Subject: Vapor-Intrusion Investigation and Sub-Slab-Depressurization-System Operation,
Round 27 August 2019 Monitoring Report
Lockheed Martin Corporation – Middle River Complex
2323 Eastern Boulevard, Middle River, Baltimore County, Maryland

Dear Mr. Dietz,

For your review please find enclosed two hard copies with a CD of the above-referenced document. This report documents the second round of indoor air and sub-slab vapor monitoring for calendar year 2019 at the Lockheed Martin Middle River Complex in Middle River, Maryland. This report contains the Round 27 (August 2019) monitoring results for Buildings A, B, and C, and background sampling locations. This report also includes a status update of the two sub-slab-depressurization vapor-intrusion-mitigation systems originally installed at the Middle River Complex in 2008.

If possible, we respectfully request to receive MDE's document review comments by March 25, 2020.

Please let me know if you have any questions. My office phone is (301) 548-2209.

Sincerely,

Thomas D. Blackman

SECTION 1
INTRODUCTION

Tetra Tech, Inc., (Tetra Tech) has prepared this report on behalf of Lockheed Martin Corporation (Lockheed Martin) to document the second round of indoor air (IA) and sub-slab vapor (SV) monitoring for calendar year 2019 at the Lockheed Martin Middle River Complex (MRC) in Middle River, Maryland. This report contains the Round 27 (August 2019) monitoring results for Buildings A, B, and C, and background sampling locations. This report also includes a status update of the two sub-slab-depressurization (SSD) vapor-intrusion-mitigation systems originally installed at the Middle River Complex in 2008: one beneath the Building A plating shop and the other beneath the southern portion of the Building C basement. This monitoring is part of an ongoing investigation to evaluate whether volatile organic compounds (VOCs) in sub-slab vapors (associated with soil and groundwater chemicals of concern [COC] at the site) might be moving into indoor air at Middle River Complex facilities, and to evaluate whether subsurface vapor contamination remains at concentrations dictating continued operation of the sub-slab-depressurization mitigation system, or if a transition/exit strategy can be performed. The second monitoring round for calendar year 2019 continues investigations previously described in the reports listed in Table 1-1.

This report is organized into the following sections:

- Section 2—Round 27 Indoor-Air and Vapor-Intrusion Investigation: Briefly summarizes previous investigations and interim measures and describes the sampling methodology used for the current investigation round.
- Section 3—Round 27 Results: Presents the results of the August 2019 investigation.
- Section 4—Sub-Slab-Depressurization-System Data Analysis: Summarizes the operation and monitoring of the sub-slab-depressurization systems in Buildings A and C for the reporting period from April 1 to September 30, 2019.

- Section 5—Conclusions: Presents conclusions based on the Round 27 sampling results.
- Section 6—References: Lists the references used in this report.

Tables, figures, and appendices are at the end of the report body following Section 6.

SECTION 2
ROUND 27 INDOOR-AIR-QUALITY AND VAPOR-INTRUSION INVESTIGATION

This section briefly summarizes previous investigations and interim measures and describes the sampling methodology used in the current investigation round.

2.1 PREVIOUS INVESTIGATIONS AND INTERIM MEASURES

The indoor air (IA) and sub-slab vapor (SV) investigation described herein was initially designed to evaluate whether volatile organic compounds (VOCs) associated with soil and groundwater contamination at the site might be moving into IA at Middle River Complex (MRC) facilities. Tetra Tech, Inc. (Tetra Tech) industrial hygienists chose the initial sampling locations for Buildings A, B, and C during a 2006 site reconnaissance. Additional sampling locations were selected throughout program implementation based on previous IA and SV monitoring results, site conditions, and internal operations (Tetra Tech, 2017d).

Although IA results had predominantly been below risk-based screening levels after the first three rounds of sampling in February 2006, December 2006, and April 2007 (with one trichloroethene [TCE] exceedance in 109 samples [1]), two sub-slab depressurization (SSD) vapor intrusion mitigation systems (one beneath the former Building A plating shop and the other beneath the southern portion of the Building C basement) were installed at the MRC in 2008 (Tetra Tech, 2008d), based on elevated SV concentrations detected beneath the buildings. The Building A SSD system (SSDS) was expanded in 2010 (Tetra Tech, 2010c), in 2016 (Tetra Tech, 2016d), and again

[1]One TCE concentration (36 micrograms per cubic meter [µg/m^3]) out of 109 total samples (including duplicates) exceeded the previously used MDE indoor air screening level (25 µg/m^3). The exceedance was observed in the duplicate sample of a field-duplicate pair; TCE was not detected in the corresponding parent sample. Since then, the indoor air screening level has been reduced to 8.8 µg/m^3; even so, that result would have been the only exceedance.

A site-specific TCE screening-level of 35 µg/m^3 for indoor air has been derived for the Building A basement based on limited exposure potential in the basement. This screening level was approved by the Maryland Department of the Environment (MDE) in July 2017. However, the site-specific screening level for the basement does not represent a final risk-based indoor air cleanup criterion.

in 2017 (Tetra Tech, 2017f) after elevated SV concentrations were detected at additional locations. The Building C SSDS was expanded in 2012 (Tetra Tech, 2012c) and 2013 (Tetra Tech, 2013c) for similar reasons (elevated SV concentrations in the central portion of the basement). Subsequent rounds of IA sampling indicated that main floor contaminant concentrations in IA resulting from vapor intrusion (VI) were being controlled by the SSDSs.

Building A Vapor Assessment and Mitigation Optimization

However, recent investigations in Building A and the Building A basement have identified elevated TCE concentrations in SV, water (groundwater and water in sumps), and in basement IA. The following presents a list of subsequent VI investigations in Building A and the Building A basement from 2014–2018, followed by a more detailed description of each investigation:

(a.) portable gas-chromatograph/mass-spectrometer (GC/MS) surveys of IA and sub-slab air from within Building A basement floor features (e.g., sumps, drains) in February 2014 and April 2016 (Tetra Tech, 2014b, 2016b)

(b.) installation of three portable air-filtration units in January 2015 in the Building A basement to mitigate TCE exceedances in indoor air (Tetra Tech, 2016d)

(c.) installation and sampling of additional Vapor Pin™ vapor monitoring points (VMPs), including seven in the eastern wall of Building A basement, two in the Building A basement floor, and one beneath the main floor of Building A in March 2016 (Tetra Tech, 2016b)

(d.) collection of air and water samples from select floor features (i.e., sumps, drains) in Building A basement in May 2016 (Tetra Tech, 2016b, 2016c)

(e.) a continuous air-monitoring survey of SV and breathing-zone IA in the Building A basement over two months (February 24 to April 21, 2017) (Tetra Tech, 2017b)

(f.) a test to determine the effects resulting from covering select floor features (e.g., sumps and drains that had exhibited the highest TCE concentrations) on basement IA concentrations in March 2017 (Tetra Tech, 2017b)

(g.) flow testing in two sumps in the southern portion of Building A basement to determine the volume of water being discharged from each individual sump back to Lift Station #5 in March–May 2018; and sampling of water in Building A basement sumps in March 2018, including water from a sump (not previously sampled) in the utility corridor between Building A basement and the Drop Hammer Building; an assessment of the data obtained from this study sought to determine a constructible, cost-effective

solution that effectively controls water and vapor accumulation in the sumps (Tetra Tech, 2018e).

Elevated TCE concentrations detected in air within, and above, select floor features (e.g., sumps) in the Building A basement led to the installation (as an interim measure) of three additional air-purifying filters (for a total of six filters) in the basement in May 2017 (Tetra Tech, 2018b). The continuous air-monitoring survey also identified significant sources of IA contamination in the basement at sumps associated with abandoned and/or removed heaters (Tetra Tech, 2017b). In addition to the new air-purifying filters, additional activities were completed in the summer of 2017 in Building A and its basement to address the elevated VOC results in SV and sump water from several recent investigations. A closed-circuit television (CCTV) camera survey of floor features in the Building A basement, including the sumps in existing and former heating rooms, the air-duct network that runs behind the eastern basement wall, the storm-drain line that runs north/south under the basement floor, and the smaller floor drains, was conducted to determine their condition, identify possible breaches, and better understand their direction and design. The CCTV survey indicated that the underground network of floor drains, pipes, and manholes/sumps are interconnected. Floor drains that might have mitigated water infiltration in and near pits associated with former equipment in Building A appeared to be connected to nearby sumps and storm drains. Other floor drains appeared to have been abandoned, which is supported by information received while conducting historical interviews of on-site personnel (Tetra Tech, 2018b).

In March/April 2016 (Tetra Tech, 2016b) and March 2017 (Round 22), sampling location SV-175-A (Figure 2-1) on the Building A basement floor had the highest TCE concentrations (460,000 and 650,000 micrograms per cubic meter [$\mu g/m^3$], respectively). The maximum August 2017 (Round 23) SV TCE concentration (21,000 $\mu g/m^3$) was also detected at location SV-175-A. Location SV-175-A was removed from the sampling list and not sampled in February 2018 (Round 24) since consistently elevated TCE concentrations detected during previous sampling negated the need to continue collecting data from this location at that time. High TCE SV concentrations (2,500 $\mu g/m^3$ to 16,000 $\mu g/m^3$) were also noted at two locations (SV-171-A and SV-173-A) in the eastern wall of the Building A basement during 2016 (Tetra Tech, 2016b), at three locations (SV-170-A, SV-171-A, and SV-173-A) in the eastern wall of the Building A basement in

2017 (in both the March [Round 22] and August [Round 23] sampling), and at two locations (SV-171-A and SV-173-A) in the eastern wall of the Building A basement in February 2018 (Round 24).

These high TCE concentrations prompted a pilot test conducted on July 6, 2017; this test evaluated the feasibility of extracting vapors from within the basement duct system at former heater room A-9/sump HRS-5 (located immediately adjacent to SV-175-A, where the highest TCE concentrations have been detected historically) using the existing SSDS (Tetra Tech, 2018b). The pilot test was successful, HRS-5 was left connected to the SSDS, and the system continues to extract vapor from this sealed sump.

In July 2017 (Tetra Tech, 2017b), a FROG 4000™ gas-chromatograph/photoionization detector (GC/PID) survey of the main floor of Building A assessed whether TCE detected in indoor air near the basement sumps was migrating through air ducts connected to the sumps, and through the floor air-vents, to the main floor of Building A. TCE detections ranging from 32.8 µg/m^3 to 103.7 µg/m^3 were recorded in samples collected from inside the vents and in IA above the vents; therefore, in September 2017 each air vent on the main floor (regardless of screening results) was sealed using a vapor barrier and a bolted-down steel plate. Sealing these floor vents on the main floor of Building A closed off this exposure pathway and prevented further migration of TCE vapor from the basement. A subsequent FROG 4000™ survey in October 2017 verified seal integrity at the 42 air-vent locations and confirmed the absence of IA TCE near the vents. No TCE was detected in any IA sample collected; all results were non-detected (Tetra Tech, 2018c).

In January–May 2018, Tetra Tech conducted an inspection of the sump pumps in Building A basement and conducted flow testing in two sumps (SP1/SP1A and the utility corridor sump) in the southern portion of Building A to measure the volume of water being discharged (via polyvinyl chloride [PVC] piping) from each sump to sanitary sewer Lift Station #5. Water samples were also collected from sumps in Building A basement during this investigation. Information gained from the January–May 2018 studies was used to determine constructible, cost-effective solutions that control water and vapor accumulation in Building A basement sumps (Tetra Tech, 2018e). Mitigation strategies have been proposed and subsequently approved by Maryland Department of the Environment (MDE) (Tetra Tech, 2019), and will be implemented (starting in December 2019) with the abandonment of sump HRS-5. After monitoring for potential unintended consequences

(i.e., flooding of the basement), two additional sumps (HRS-6 and HRS-7) in the southern portion of Building A basement will be abandoned. There are no plans to mitigate sumps SP1/SP1A and the utility corridor sump.

The sump inspection determined that the pump in sumps SP1/SP1A was the only one in the target area (southern portion of Building A basement) that pumps a significant volume of water back to Lift Station #5, and subsequently the sanitary sewer system. Only a small amount of water (less than three gallons) was collected in the utility corridor sump over a two-month period. The respective TCE concentrations detected in sump water at SP1/SP1A during the last three sampling events were: 120 microgram(s) per liter (µg/L) and 2,700 µg/L in May 2016; 160 µg/L and 440 µg/L in March 2017; and 160 µg/L (SP1 only)[2] in March 2018. The TCE concentration detected in the utility corridor sump was 53 µg/L. These concentrations are two to three orders of magnitude higher than the TCE concentrations (2.3 µg/L and 2.6 µg/L) detected in water samples collected from Lift Station #5, indicating that dilution is likely occurring at the lift station due to the other discharged water it receives. Various pipes discharge into the lift station, including those carrying heating, ventilation, and air conditioning (HVAC) condensate water. This additional water is likely responsible for the apparent low concentration of TCE concentrations detected at Lift Station #5 as compared to the concentrations detected at the sumps.

2.2 INVESTIGATION PROCEDURES

The sampling plan for Round 27 was based on historical detections, information obtained during site reconnaissance, and a review of historical information and reports. IA and SV samples were collected from Buildings A, B, and C during Round 27 sampling. Relevant guidance from the United States Environmental Protection Agency [USEPA] (USEPA, 1996, 2004, 2012, and 2015) and the Maryland Department of the Environment [MDE] (MDE, 2006) was used to develop the investigation methodology.

[2]The only sample collected in March 2018 was from SP1, as the focus at that time was on that sump. Note that sumps SP1/SP1A are connected underground.

2.2.1 Sampling Approach

IA and SV sampling within Buildings A, B, and C was completed in accordance with the work plan for Rounds 24–29 (Tetra Tech, 2017d). Background outdoor air samples were collected from the same sampling locations as had been used for the previous Round 26 (Figure 2-2). Not all existing monitoring points inside the subject buildings were sampled during Round 27. As in previous rounds, samples were selectively collected in or adjacent to areas where contaminants had been detected previously, or in areas where contaminants are currently suspected of being present.

TCE has been targeted as a primary chemical of concern (COC); it has a history of use at the site; has been detected in groundwater and soil gas; can be toxic to human health depending upon the dose received and the duration and means of exposure; and is mobile in the environment. Historical sampling locations and the sub-slab VMPs sampled in Buildings A, B, and C during this round are shown in Figures 2-3, 2-4, and 2-5, respectively. IA sampling locations were co-located with most of the monitored SV sampling locations to evaluate IA and any possible relationship between SV and IA in Building A, B, and C.

Round 27 sampling was performed on August 14 and 15, 2019. Seventy-two samples (and eight duplicates) were collected using Summa® canisters as follows:

- four background ambient-air samples were collected at the same locations used in the previous round
- 35 IA samples (and four duplicates) from Buildings A, B, and C:
  - 15 IA samples (and two duplicates) from Building A
  - two IA samples from Building B
  - 18 IA samples (and two duplicates) from Building C
- 33 SV samples (and four duplicates) from Buildings A, B, and C:
  - 16 SV samples (and two duplicates) from Building A
  - two SV samples from Building B
  - 15 SV samples (and two duplicates) from Building C

- The "-A," "-B," and "-C" suffixes in the sampling location designations correspond with Buildings A, B, and C, respectively.

2.2.1.1 Building C Basement Machine Shop

Five IA samples from Building C (144-C, 145-C, 146-C, 150-C, and 152-C) were collected in the machine shop of the Lockheed Martin Rotary and Mission Systems (RMS) (formerly the Lockheed Martin Mission Systems & Training [MST] mechanical prototype laboratory [MPL]). Monitoring continues in this area because TCE was detected in IA at a concentration greater than its screening level during Round 15 (August 2013). The five sampling locations that provide data for possible worker-exposure areas within the MPL are:

- 144-C: machine shop area
- 145-C: cubicle area
- 146-C: kitchen area
- 150-C: kitchen area
- 152-C: machine shop area

2.2.1.2 Building A Basement

Five SV samples (three in the eastern wall of the Building A basement [170-A, 171-A, and 173-A], one in the Building A basement floor [174-A], and one beneath the main floor of Building A [168-A]), were collected during Round 27 to target possible TCE sources, including a former underground storage tank and vapor degreasers associated with former plating shop operations.

2.2.2 Sampling Procedures

Before SV sampling, the tubing for each VMP was purged of atmospheric air, allowing SV to enter the probe and tubing. Purging was performed by attaching the sample tubing to a low-flow sampling pump set to an approximate flow rate of 200 cubic centimeters per minute to minimize the potential mobilization of SV that could bias the sample. Three volumes (i.e., the volume of the sample probe and tube) were purged to ensure that collected samples were representative of SV conditions. IA samples were collected at standard breathing-zone levels as on-site conditions allowed (e.g., on a shelf, or top of cabinet); otherwise, IA samples were collected on the ground surface. Select samples were co-located with the corresponding SV sampling locations.

Each SV sample was collected over one hour and each IA sample was collected over an eight-hour period using preconditioned Summa® canisters to ensure subsurface equilibration and avoid high negative pressure that might mobilize SV and bias the IA results. The one-liter stainless-steel canisters were equipped with in-line particulate filters and integral controllers that control the rate of filling during sampling. SV samples were collected through Teflon® tubing attached to the stainless-steel Vapor Pins® or vapor implants. Each sampling location was routinely inspected during the sampling period to ensure appropriate operation of sampling devices, sample integrity, and to document conditions within the area that might affect results. Samples were collected by opening the valve on the canister, which allowed air to enter the canister at the rate set by the controller (a one-liter canister over a period of one hour [for SV] and over a period of eight hours [for IA]). Controllers were calibrated in the laboratory and shipped to the field with a sufficient flow rate that would maintain the necessary vacuum pressure in the Summa® canister for the one-hour and eight-hour sampling intervals. Samples were collected and analyzed for VOCs by USEPA Method Toxic Organic-15 (TO-15). SV samples were collected in accordance with standard operating procedures developed by the USEPA Environmental Response Team for soil vapor sampling (USEPA, 1996), and methodologies developed by the USEPA Office of Research and Development (USEPA, 2004). After sampling had been completed, each canister was closed and sent to an off-site laboratory (TestAmerica, Inc. in Knoxville, Tennessee) under proper chain of custody procedures.

2.2.3 Observations

The SSD systems in the Building C basement area and the Building A plating shop were shut down approximately 24 hours before sampling began. The SSD systems were restarted within one hour after sampling had been completed in Buildings A and C; this is consistent with previous monitoring episodes. The following observations were recorded during the August 2019 sampling:

- Mean outdoor ambient temperature during the sampling period was 79 degrees Fahrenheit (°F) on August 14, 2019 and 78°F on August 15, 2019. Barometric pressure increased slightly during the sampling period, from 29.63 inches of mercury (in. Hg) to 29.84 in. Hg. Wind direction on August 14 was from the west/northwest and on August 15 from the east/northeast, with average wind speed ranging from calm to 13 miles per hour (mph). Skies were mostly cloudy on August 14 and August 15, 2019.

- No precipitation (rain) was recorded on August 14 or August 15, 2019.

- Water was present in the Building B flush-mounted vault (shallow subsurface groundwater accumulation) at sampling locations 121-B and 140B, preventing sample collection. Alternate IA and SV samples were collected at nearby locations 101-B and 100-B, respectively.

- IA and SV samples from 118-A and SV sample from 139-A were collected in the bond-layup room (Building A production floor), where a positive-pressure air-conditioning system was operating. The door adjacent to 139-A was opened and closed frequently during sampling.

- The lid for sample location 081-A could not be removed because it had been painted over when the floor was painted; therefore, an SV sample was not collected at 081-A. A replacement SV sample was collected at nearby location 139-A.

- Sampling location 015-A is in the former plating shop area (Building A production floor). After the sampling round in August 2015, this area had undergone redevelopment and construction. A new floor has been installed, and this area is now an extension of the bond-layup room. IA and SV samples from 015-A were collected in this newly expanded bond-layup room (former plating shop), where a positive-pressure air-conditioning system was operating.

- Sampling locations 018-A, 093-A, 116-A, and 138-A were collected in the Building A basement. Samples from four locations in the basement were added to the sampling program in the work plan (Tetra Tech, 2017d) due to ongoing TCE VI investigation there. These include three additional sampling locations in the eastern wall (170-A, 171-A, and 173-A) and one in the floor (174-A).

- The air-purifying units in the Building A basement were operating when samples were collected.

- Several IA and SV samples (018-A, 021-A, 075-A, 078-A, 079-A, 081-A, 117-A, 118-A, 100-B, and 101-B) were collected near operating overhead ceiling fans and/or floor fans used to cool the building during warmer months.

- A paint and dangerous goods labeled cabinet was located near IA and SV sampling location 0136-A.

- Painting and copper shavings were being conducted near IA and SV sampling location 076-A.

- Painting and dust were located in the area of IA and SV sampling location 101-B.

- The IA and SV samples from 168-A were collected near the location of a former vapor degreaser on the main floor of Building A.

- IA and SV samples in Building C basement at locations 001-C and 004-C were collected approximately 70 feet from a bay door to the outside that was opened intermittently.

- Samples IA-144-C through IA-146-C, IA-150-C, and IA-152-C in Building C basement were collected in a positive-pressure, air-conditioned room (the RMS MPL machine shop).

- Building A is a one-story building, except for a basement corridor under an open-air loading dock on its western side. Roof vents approximately 50 feet above the work floor were open in Building A during Round 27 sampling. The large doors at the loading docks on the western side of the building were also open to allow carts, forklifts, personnel, and equipment to pass. Increased ventilation associated with open doors and roof vents might have affected concentrations in samples collected on the first floor of Building A. No personnel or other activities were observed in the Building A basement.

- The bay doors across the southern end of Building B were open during sampling. The automatic bay door at the southeastern corner of Building B was opened and closed quickly to allow carts and equipment to pass. The opening of the bay doors might affect concentrations in samples collected from the southernmost sampling locations (IA-100-B and IA-101-B). Open roof vents were also observed in Building B during sampling.

- The Building C basement is generally accessed via two automatic rolling doors on its eastern and southern sides. These doors open and close quickly to allow carts and forklifts to pass. The automatic rolling door approximately 40 feet east of sampling location 141-C was opened and closed intermittently during the day. The bay doors at the southern and southeastern sides of the Building C basement were open during the sampling period. This might have influenced IA concentrations in the samples collected from locations 001-C and 004-C.

- The most personnel and greatest activity were observed in Building B, in locations from the thrust-reverser assembly area in the southern portion of the building to the machining area in its central portion. Similar activity was observed in Building A, where activity was generally focused in the expanded bond-layup room (former plating shop area) and autoclave areas, and in the parts and assembly areas. No activity was observed in the southern portion of Building C. Light activity (three people) was observed in the machine shop area in Building C basement.

- The southern end of the Building C basement is mostly vacant, having been cleared of workstations and equipment by MRA Systems, Inc. (MRAS) (Note that ownership of MRAS was transferred from General Electric (GE) to Singapore Technologies Engineering, Ltd. (ST Engineering). Some materials are being temporarily stored in this area.

- The pressure gauges on most Summa® canisters responded instantaneously upon opening the valve by dropping to between -25 in. Hg and -30 in. Hg. Two pressure gauges (IA-145-C and IA-DUP2-C) had beginning pressures of less than - 25 in. Hg. The ending readings on pressure gauges of most Summa® canisters were between -3 in. Hg and -9 in. Hg when

sampling was complete. Despite these varied pressure readings and faulty gauges, all regulators operated properly and collected adequate sample volumes. Pressure readings for each Summa® canister are recorded on the chain of custody forms (Appendix A).

Samples were analyzed for the current target-compound list, last amended on February 12, 2012:

- 1,1,1-trichloroethane (1,1,1-TCA)
- 1,1,2-trichloroethane (1,1,2-TCA)
- 1,1-dichloroethane (1,1-DCA)
- 1,1-dichloroethene (1,1-DCE)
- 1,2,3-trimethylbenzene (1,2,3-TMB)
- 1,2,4-trichlorobenzene
- 1,2,4-trimethylbenzene (1,2,4-TMB)
- 1,2-dichloroethane (1,2-DCA)
- 1,3,5-trimethylbenzene (1,3,5-TMB)
- Benzene
- carbon tetrachloride
- chlorodifluoromethane (Freon 22)
- chloroform
- *cis*-1,2-dichloroethene (*cis*-1,2-DCE)
- dichlorodifluoromethane
- ethylbenzene
- methylene chloride
- methyl-tertiary-butyl ether (MTBE)
- naphthalene
- tetrachloroethene (PCE)
- toluene
- *trans*-1,2-dichloroethene (*trans*-1,2-DCE)
- trichloroethene (TCE)
- vinyl chloride (VC)
- xylenes (total)

All samples collected during Round 27 were submitted to TestAmerica in Knoxville, Tennessee, for analysis via GC/MS using cryogenic concentration (as described in Sections 9 and 10 of USEPA Method TO-15 [USEPA, 1999]). This method was used because of its low detection limits (in the parts-per-billion by volume range), and because it can quantify all VOCs of concern. TestAmerica is certified in USEPA Method TO-15 analysis and meets all quality assurance/quality control requirements specified in the TO-15 methodology.

All samples were stored at ambient temperatures and shipped to the laboratory via overnight carrier. All samples were submitted and analyzed within the method's specified 30-day holding time. All appropriate chain of custody documentation was completed for each sample (see Appendix A). A table listing TestAmerica's method detection limits is in Appendix B; Appendix C contains the laboratory analytical reports. Data-validation reports and supporting documentation are in Appendix D.

Validated analytical data were qualified in accordance with USEPA *National Functional Guidelines for Organic Superfund Methods Data Review* (USEPA, 2017). Attaching data qualifiers to analytical results signifies a quality-control noncompliance. During Round 27, the following data qualifiers were applied to data after validation if applicable:

- *J*—indicates an estimated result below the reporting limit, or an estimated result greater than the reporting limit with a quality control nonconformance.
- *U*—indicates the chemical was not detected at the numerical detection limit (i.e., at the sample-specific quantitation limit).
- UJ—indicates the chemical was not detected at the (estimated) numerical detection limit (i.e., the sample-specific quantitation limit).

Field duplicate sampling results were evaluated based on the following criteria: a relative percent difference of less than or equal to 50% when both original and duplicate results were greater than the reporting limit, or a difference within two times the reporting limit when original and duplicate results were less than or equal to the reporting limit. Detected results for chlorodifluoromethane and methylene chloride in sample IA-088-C-27 and its corresponding duplicate were qualified as estimated (*J*) due to field duplicate precision, as were detected results for 1,1-DCE, ethylbenzene, and total xylenes in sample SV-102-C-27 and its corresponding duplicate (Appendix D). In addition, detected results for methylene chloride in sample SV-116-A-27 and its corresponding duplicate were qualified as estimated (*J*) due to field duplicate precision (Appendix D). No other results were qualified for field duplicate imprecision during Round 27. Original and field duplicate results were considered separately when evaluating exceedances; i.e., if an analyte's concentration in either the original or duplicate sample exceeded criteria, that exceedance is noted. In summary statistics (e.g., frequency of detection counts), field duplicate pairs were counted as one sample, and calculated averages were reported (e.g., in the "average of all values" calculation), as shown on Section 3 tables.

In addition to the results qualified for field duplicate imprecision, several other minor issues were identified during data validation. Some results were qualified as estimated (*J* or UJ, as applicable) for calibration noncompliance. Several detected results were also qualified as estimated (*J*) due to laboratory-identified chromatographic interference, laboratory control sample noncompliance, or uncertainty near the detection limit for detections less than the reporting limit. Additionally,

methylene chloride results in several samples were qualified as non-detected (*U*) or estimated (*J*) due to laboratory blank contamination. However, no major problems were identified during data validation.

2.3 OCTOBER 2019 RESAMPLES

The Building A SSDS was discovered offline during the September 23, 2019 system check, and based on the SSDS hour counter reading taken at that time, the system had not been operating since September 11, 2019. This prompted additional IA sampling at seven locations (015-A, 018-A, 021-A, 079-A, 117-A, 136-A, and 168-A) within or close to the radius of influence of the Building A SSDS on October 2, 2019. This resampling was conducted to determine the quality of IA in Building A and Building A Basement after the 12-day SSDS shutdown. Results of the October sampling are discussed separately in Section 3. During the October resampling event the following observations were recorded:

- A large fan was on and running inside the room when sample IA-018 was collected.
- A large fan (located about 20 feet away) was pointed in the general direction of IA-136, and that fan was turned on at some time during the eight-hour sample collection period.
- Workers were painting approximately 100 feet away from sampling location IA-117 when the Summa canister was picked up; the painting had started at some time after initial placement of the Summa® canister.

SECTION 3
ROUND 27 RESULTS

All analytical results for indoor air (IA) and background (ambient air) samples were compared to screening levels for industrial air; these levels are based on United States Environmental Protection Agency (USEPA) *Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites* (USEPA, 2019). Screening the chemicals of concern (COC) uses the lower of the carcinogenic (*ca*) or noncarcinogenic (*nc*) values. Carcinogenic values are based on a 1×10^{-5} (i.e., a one-in-100,000 probability) excess cancer-risk, whereas the noncarcinogenic values are based on a hazard quotient of 1 (i.e., the "no adverse effect" level). For samples collected in the Building A basement only, indoor air levels of trichloroethene (TCE) were compared to a Maryland Department of the Environment (MDE)-approved basement-specific screening level of 35 micrograms per cubic meter ($\mu g/m^3$), based on the limited exposure potential for workers entering the basement.

These risk benchmarks were selected in accordance with Maryland Department of the Environment (MDE) requirements. Analytical results were also compared to federal Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs). Alternate values, such as the "Threshold Limit Values" published by the American Council of Governmental Industrial Hygienists, were used for chemicals without published permissible exposure limits.

Sub-slab vapor (SV) sampling results were compared to SV screening values derived in accordance with the methods discussed in USEPA's *OSWER Technical Guide for Assessing and Mitigating the Vapor Intrusion Pathway from Subsurface Sources to Indoor Air* (USEPA, 2015), and were calculated by dividing indoor-air (IA) screening levels by a conservative attenuation factor (AF) of 0.03. The AF represents the adjustment applied to IA screening levels to account for concentration reductions due to diffusive, advective, and/or other attenuating mechanisms as vapor migrates from the sub-slab to IA. Simply stated, SV is expected to dilute upon movement into IA; the AF is the ratio of the IA concentration to its SV concentration under a conservative

vapor-intrusion (VI) scenario. The recommended AF in the 2015 USEPA guidance results in higher SV screening values than those used for sampling rounds before August 2012, when an earlier USEPA AF of 0.1 was used. USEPA further acknowledges that applying the AF of 0.03 to industrial buildings is conservative (i.e., more protective of human health and the environment), because the value was developed based on residential VI studies and does not account for industrial buildings that generally have thicker building slabs and stronger heating/ventilation/air-conditioning (HVAC) systems than residential homes.

3.1 ROUND 27 DATA ANALYSIS

The sampling-round designation (R27) is not included when identifying samples or sampling locations in the following text, because all data discussed in this section are from Round 27. For example, an IA sample collected from vapor monitoring point (VMP) 076 (e.g., sample IA-076-A-R27) is referred to as "076-A." If comparisons are made to specific samples from previous sampling rounds, they will be identified as such in the text or by using the round-designation suffix (e.g., R06 for Round 6).

Descriptive statistics for Round 27 IA and SV samples are shown in Tables 3-1 and 3-2, respectively. Summary statistics for TCE and naphthalene in IA over time are shown in Tables 3-3 and 3-4, respectively, and indicate that detected concentrations of TCE and naphthalene from Round 27 are less than or within the ranges of concentrations detected during previous sampling rounds. Figures 3-1, 3-2, and 3-3 show Round 27 exceedances in Buildings A, B, and C, respectively. The following chemicals were detected in Round 27 IA and/or SV samples at concentrations exceeding their respective MDE industrial risk-management benchmarks:

- IA—naphthalene and TCE
- SV—1,1-dichloroethane (1,1-DCA), TCE, and vinyl chloride (VC)

3.1.1 Building A

Tables 3-5 and 3-6 present the Building A IA and SV results, respectively. Locations with exceedances are shown in Figure 3-1. One detected IA concentration (9.3 µg/m^3) of TCE at location 093-A in the basement exceeded its project IA screening level of 8.8 µg/m^3, but was less than the basement-specific TCE screening level of 35 µg/m^3, and is therefore not an exceedance.

Additionally, one detected naphthalene IA concentration (4.3 µg/m^3) in the duplicate sample collected at 018-A was greater than its screening level (3.6 µg/m^3); however, naphthalene was not detected in the corresponding parent sample at 018-A.

TCE was the only analyte detected in SV at concentrations exceeded screening levels. TCE was detected in all Round 27 SV samples and exceeded its screening level (293 µg/m^3) in six samples; TCE is further discussed below.

3.1.1.1 TCE in Building A Basement

Beginning in Round 15 (August 2013), TCE has periodically been detected in IA in the Building A basement at concentrations greater than its project IA screening level (8.8 µg/m^3), including Round 17 (August–November 2014), Round 20 (February 2016), Round 22 (March 2017), Round 25 (August 2018), and Round 27 (August 2019). However, IA TCE concentrations have not exceeded the Building A basement-specific screening level for TCE (35 µg/m^3) approved by MDE in 2017. The basement screening-level was developed to account for reduced exposure potential in the basement, as compared to exposure on the main floor of Building A. Access to the Building A basement is controlled by management.

TCE was detected in IA at all four Building A basement sampling locations (018-A, 093-A, 138-A, and 174-A) in Round 27, but at concentrations less than its basement-specific screening level. Detected IA TCE concentrations were 3.9 µg/m^3 and 3.6 µg/m^3 in parent and duplicate samples (respectively) at location 018-A, 9.3 µg/m^3 at location 093-A, 5.1 µg/m^3 at location 138-A, and 8.2 µg/m^3 at location 174-A.

Note that this is the fifth VI sampling round since vapor extraction began at the HRS-5 sump. This sump has been identified as likely the primary contributor of TCE impacts to indoor air in the Building A basement. Vapor is now being extracted there continuously under normal sub-slab depressurization system (SSDS) operating conditions; however, per sampling protocol, the SSDS was temporarily shut down for approximately 24 hours before IA and SV sampling started, and restarted immediately after sampling had been completed.

TCE exceeded its SV screening level (293 µg/m^3) at four basement locations (170-A, 171-A, 173-A, and 174-A) in the central portion of Building A, near or within the radii of influence of the sub-slab depressurization (SSD) systems; exceedances were 340 µg/m^3 at 170-A, 2,200 µg/m^3 at 171-A, 10,000 µg/m^3 at 173-A, and 4,400 µg/m^3 at 174-A. Locations 170-A, 171-A, and 173-A are in the eastern wall of the Building A basement and 174-A is in the basement floor; these locations were added to the semiannual IA/SV sampling in Round 22. SV TCE concentrations at sampling locations 171-A and 173-A have been exceeding the screening level since Round 22. SV TCE concentrations at sampling locations 170-A and 174-A also exceeded the screening level in several previous sampling rounds since they have been added to the sampling program.

3.1.1.2 TCE in First Floor of Building A

TCE (0.21*J* µg/m^3) was detected in IA in only one of 11 Round 27 first-floor Building A samples at a concentration an order of magnitude below its IA screening level (8.8 µg/m^3).

SV TCE exceeded its screening level (293 µg/m^3) at only two first floor locations, 118-A (420 µg/m^3) and 136-A (500 µg/m^3), during Round 27. Location 118-A is in the central portion of Building A and within the radii of influence of the SSD systems. Location 118-A is within the bond-layup room, where a positive-pressure-air-conditioning system was operating at the time of sample collection. TCE SV exceedances have been consistently observed at this location (118-A) since Round 18. TCE SV concentrations at 118-A in Round 19 (900 µg/m^3), Round 20 (2,300 µg/m^3), Round 21 (890 µg/m^3), Round 22 (2,000 µg/m^3), Round 23 (690 µg/m^3), Round 24 (1,500 µg/m^3), Round 25 (590 µg/m^3), Round 26 (1,800 µg/m^3), and Round 27 (420 µg/m^3) are all at least one order of magnitude (i.e., a power of 10) less than the SV concentration detected in Round 18 (13,100 µg/m^3).

SV TCE exceedances were also noted at location 136-A (in the eastern portion of Building A, near the radius of influence of the SSD system) in Rounds 20 through 25. However, the SV TCE concentration at this location during Round 26 was 270 µg/m^3 (less than the SV screening level of 293 µg/m^3). SV TCE concentrations at SV 136-A in Round 21 (850 µg/m^3), Round 22 (300 µg/m^3), Round 23 (790 µg/m^3), Round 24 (380 µg/m^3), Round 25 (660 µg/m^3), Round 26 (270 µg/m^3), and Round 27 (500 µg/m^3) have decreased by a factor of approximately 100 since the SSDS was

expanded to this location in 2016, after a reported TCE-vapor concentration of 35,000 µg/m^3 during Round 20.

The SV TCE concentration at first floor location 168-A, added to the semiannual sampling in Round 22 (and located within the radii of influence of the SSD systems), was less than the screening level during Rounds 26 and 27, but exceedances were noted at this location during previous sampling rounds including Round 25. SV TCE concentrations at sampling location 168-A exceeded the screening level in Rounds 22 through 25 (22,000 µg/m^3 [in Round 22]; 8,300 µg/m^3 and 7,900 µg/m^3 [for original and duplicate, respectively, in Round 23]; 1,300 µg/m^3 [in Round 24]; and 950 µg/m^3 and 920 µg/m^3 [for original and duplicate, respectively, in Round 25]), but have notably decreased over time following the SSDS expansion. Concentrations at location 168-A during Round 26 and 27 were 180 µg/m^3 and 270 µg/m^3, respectively, and were less than the SV TCE screening level (293 µg/m^3).

3.1.2 Building B

Tables 3-7 and 3-8 present Building B IA and SV results, respectively. Sampling locations within Building B are shown on Figure 3-2. No IA or SV exceedances were noted during Round 27. Similarly, no exceedances were noted in Building B IA or SV samples during Rounds 19 through 26. During Round 18, only one slight naphthalene exceedance (4.2 µg/m^3) was detected in IA at location 140-B, and this concentration only marginally exceeded its screening level (3.6 µg/m^3). No exceedances were noted in Building B IA or in SV samples during Round 17. Prior IA naphthalene exceedances were noted at locations 140-B (6.5 µg/m^3) and 0-33B (4*J* µg/m^3) during Round 16 (February 2014), 033-B (5 µg/m^3) during Round 15 (August 2013), and 057-B (3.8 µg/m^3) during Round 6 (July 2009). Prior naphthalene exceedances of the SV screening level (120 µg/m^3) were noted at several locations during Rounds 6, 9, and during Rounds 11 through 15, with the most recent exceedances at locations 140-B (250 µg/m^3) and 123-Z (160 µg/m^3) during Round 15 (August 2013).

3.1.3 Building C

Tables 3-9 and 3-10 present Building C IA and SV results, respectively. All detected IA concentrations were less than their associated screening levels during Round 27.

TCE was detected in three of 18 IA samples, but at low concentrations (0.54*J* µg/m^3 to 1.1*J* µg/m^3) and less than its screening level (8.8 µg/m^3). TCE was detected at all 15 SV sampling locations, and TCE exceedances in SV were noted at four locations (Figure 3-3):

- 060-C (570 µg/m^3), in the east-central portion of Building C, and within the SSD radius of influence
- 102-C (1,200 µg/m^3 and 890 µg/m^3 in parent and duplicate samples, respectively), in the central portion of Building C near REC #31 (former Patriot plating line), and external to the SSDS radius of influence
- 133-C (620 µg/m^3) in the central portion of Building C, north of REC #31 (former Patriot plating line), and within in the SSD radius of influence
- 141-C (330 µg/m^3), south of the museum room and north of the machine shop, in the northeastern portion of Building C, and within the SSDS radius of influence

SV TCE concentrations at 102-C also exceeded its screening level during Rounds 22 through 26. In the previous three sampling rounds (Rounds 24, 25, and 26), SV TCE exceedances were also detected at locations 060-C and 133-C, and SV TCE exceedances were detected at location 141-C during Rounds 24 and 26.

Although an SV TCE exceedance was detected in the southern portion of Building C at location 001-C during Rounds 21 and 25, no exceedance at that location was detected during Rounds 22 through 24, or during Rounds 26 and 27. An SV TCE exceedance was detected at location 113-C, in the south-central portion of the building, during Round 21, but not during Rounds 22 through 27. SV TCE exceeded its screening level at location 126-C during Rounds 22 through 26, but not during Round 27. Note that some uncertainty exists regarding Round 27 SV results for locations 126-C and 149-C, as historical trends indicate that the SV data for these locations may have been mislabeled. This is further discussed as part of the VC discussion below. Regardless, Round 27 SV concentrations of TCE at both locations (3.7 µg/m^3 at 126-C, and 200 µg/m^3 at 149-C) were less than the screening level (293 µg/m^3). SV TCE exceedances at location 152-C, in the east-central portion of Building C, were noted during Rounds 22 and 23, but not during Rounds 24 through 27. SV TCE exceedances in Building C appear to be sporadic and do not follow an observable spatial pattern.

During Round 27, a sole VC exceedance (2,700 µg/m^3) of its screening level (933 µg/m^3) was detected in SV at location 149-C. SV exceedances of VC had not been detected at location 149-C during previous rounds of sampling; however, SV exceedances of VC have consistently been observed at location 126-C since Round 12, with recent concentrations as follows: Round 18 (1,310 µg/m^3), Round 19 (16,000 µg/m^3), Round 20 (3,100 µg/m^3), Round 21 (5,000 µg/m^3), Round 22 (2,600*J* µg/m^3), Round 23 (3,300 µg/m^3), Round 24 (2,700 µg/m^3), Round 25 (6,300 µg/m^3), and Round 26 (1,100 µg/m^3). VC exceedances in SV at location 126-C have occurred during recent sampling rounds (i.e., in Rounds 12–26). As mentioned previously, historical data, as compared to Round 27 data, appear to indicate that the SV samples for locations 149-C and 126-C may have been mislabeled (switched) during the current sampling round. Note that VC was not detected in IA during Rounds 12 through 27.

In addition to the screening level exceedances discussed above, SV exceedances of 1,1-DCA (2,900 µg/m^3 and 3,800 µg/m^3 in the parent and duplicate samples, respectively) were also detected at 102-C during Round 27 (the screening level is 2,567 µg/m^3). No Round 27 SV naphthalene concentrations exceeded its screening level in Building C; however, the naphthalene concentration detected in the duplicate sample at location 102-C (120 µg/m^3) was equal to its screening level (note that the naphthalene concentration in the parent sample at this location was 77 µg/m^3). Exceedances of 1,1-DCA and naphthalene in SV were noted at location 102-C during Round 22 (3,900 µg/m^3 for 1,1-DCA and 310 µg/m^3 for naphthalene), Round 23 (5,900 µg/m^3 for 1,1-DCA, and 180 µg/m^3 for naphthalene), Round 24 (5,600 µg/m^3 for 1,1-DCA and 180*J* µg/m^3 for naphthalene), Round 25 (7,900 µg/m^3 and 7,600 µg/m^3 for 1,1-DCA in parent and duplicate samples, respectively, and 280*J* µg/m^3 and 330*J* µg/m^3 for naphthalene in parent and duplicate samples, respectively), and Round 26 (4,800 µg/m^3 for 1,1-DCA and 210 µg/m^3 for naphthalene). No exceedances were detected during Round 21. Naphthalene and 1,1-DCA were not detected in IA during Round 27 but have been detected in IA in previous sampling rounds (i.e., in Rounds 10 and 11 for 1,1-DCA, and during Rounds 10, 11, 13 through 16, 18, 23, and 25 for naphthalene) at concentrations less than screening levels.

During Round 27, IA and SV concentrations of tetrachloroethene (PCE) did not exceed its screening levels; PCE detections in IA and SV have also been below its screening level in

Rounds 18 through 26. An IA exceedance of PCE (870 µg/m^3, as compared to its IA screening level of 180 µg/m^3) was detected at location 149-C in a Round 18 resample, collected because the TCE concentration at the same location approached, but did not exceed, its screening level in the original sample. Before Round 18, PCE had never been detected in IA or SV in Building C. PCE has not been detected above its detection limit in most SV samples collected at and near location 149-C over time, suggesting that the sole PCE exceedance in IA at location 149-C during Round 18 is anomalous, and possibly attributable to some IA source rather than to VI. PCE was not detected in IA or SV at 149-C during Round 27 but was detected in SV at 126-C with a low concentration (0.29*J* µg/m^3), less than its screening level (6,000 µg/m^3). As mentioned previously, historical data patterns indicate that the SV samples for locations 149-C and 126-C may have been mislabeled (i.e., switched) in the current sampling round.

3.2 BACKGROUND AMBIENT-AIR SAMPLES

Outdoor-air-quality (i.e., background) samples provide baseline concentrations for COC that can be compared to interior concentrations. Comparison to background indicates whether chemicals detected in IA are more likely associated with an exterior (i.e., background) or interior source (e.g., chemicals used in the workplace, or with past spills of chemicals absorbed to above-slab building materials, or sub-slab sources). Analytical results for Round 27 ambient (background) air samples are shown in Table 3-11. Figure 2-2 shows the background sampling locations used for Round 27; these locations are sufficiently far from site operations to avoid any possible site influence.

Table 3-12 lists chemicals detected in background samples and compares IA concentrations to the maximum detected background concentration. Nine VOCs were detected in background samples, and all chemicals detected in background samples were also detected in IA samples. All detected background concentrations are below their respective IA screening criteria. Table 3-12 evaluates whether chemical concentrations detected in IA are possibly due to interior sources, or if they simply reflect background conditions, using the following logic:

- When IA concentrations are equal to or less than background concentrations, IA concentrations likely reflect background conditions.

- When IA concentrations are greater than background concentrations and/or sub-slab concentrations, other interior sources are possibly contributing to IA concentrations.

- The presence of chlorinated degradation-products in IA samples (at concentrations less than those detected in SV samples), but not in background samples, suggests that sub-slab sources might contribute to these IA concentrations.

The chemicals exceeding screening levels in IA (i.e., TCE and naphthalene) were not detected in background samples; therefore, IA exceedances are likely due to indoor (or possibly SV) sources rather than being reflective of background conditions. However, IA detections of several chemicals at concentrations less than screening levels may be influenced by background. As presented in Table 3-12, chemicals with most of their IA detections below background (benzene and carbon tetrachloride) are likely influenced by ambient background contaminant sources. The remaining contaminants, detected in both ambient air and in IA, might be due to IA sources (and possibly VI to IA), and/or ambient background conditions. In any case, all background contaminants also detected in IA in Round 27 are below IA screening levels.

3.3 BUILDING A SSDS SHUTDOWN EVENT INDOOR AIR RESAMPLING

As noted in Section 2.3, the Building A SSDS was discovered offline during the September 23, 2019 system check, and according to the SSDS hour counter reading taken at that time, the system had not been operating since September 11, 2019. Resampling of seven IA locations within or close to the radius of influence of the Building A SSDS (i.e., locations 015-A, 018-A, 021-A, 079-A, 117-A, 136-A, and 168-A) took place on October 2, 2019; (Figure 3-4); these sampling results are in Table 3-13. Only one IA exceedance was detected: naphthalene (9.2 µg/m^3) at location 018-A exceeded its IA screening level of 3.6 µg/m^3. Note that a naphthalene exceedance (4.3 µg/m^3) was also noted at the same location (018-A) in August 2019.

SECTION 4
SUB-SLAB-DEPRESSURIZATION-SYSTEM DATA ANALYSIS

This section summarizes the operation and monitoring activities for the sub-slab-depressurization (SSD) systems (SSDS) in Buildings A and C for the reporting period from April 1 to September 30, 2019. A detailed account of these activities is in the October 16, 2019, remedial action progress report (Appendix E). The location and layout of the SSD systems, and associated sub-slab vapor (SV) extraction points and vapor monitoring points (VMPs), along with the process and instrumentation diagrams for the Building A and Building C SSD systems, are shown in Figures 1 through 5 of Appendix E. This section discusses SV sampling results, extraction points, system influent, vacuum influence, and SSDS performance.

4.1 SUB-SLAB VAPOR MONITORING POINTS

Tables 4-1 and 4-2 summarize the concentrations of target volatile organic compounds (VOCs) detected at SV monitoring points to date near the SSD systems in Building A (in the lay-up room [former plating shop on the main floor], basement, and eastern area [on main floor]), and in the Building C basement, respectively.

4.1.1 Building A

SV samples collected to date near the Building A SSDS are listed by location in Table 4-3. VMPs 015-A (on the main floor of Building A); 078-A, 079-A, and 136-A (in the eastern area of Building A); 168-A (in the northern area of Building A); and 093-A and 116-A (in the basement of Building A) were sampled in August 2019 (see Figure 2 in Appendix E).

VMPs 015-A (on the main floor of Building A) and 018-A (in the basement) had originally been scoped to be sampled regularly as part of the facility-wide semiannual SV and indoor-air (IA) monitoring program (see Figure 2 in Appendix E). However, VMP 018-A has not been sampled

since February 2014, because water regularly collects in its flush-mounted vault. Subsequently, VMPs 093-A and 116-A were added to the SSDS monitoring program.

The highest SV trichloroethene (TCE) concentrations detected at VMPs 015-A, 018-A, 079-A, 136-A, and 168-A before and after the Building A SSDS began operation are shown in Table 4-4. The concentrations detected at VMPs 015-A, 079-A, 136-A, and 168-A in August 2019 were at least one order of magnitude (i.e., 10 times) lower than the concentrations detected before SSDS extraction began operating in the area.

While a significant decline in TCE concentrations has been observed at 015-A, concentrations continue to fluctuate over time, with some apparent seasonal variation (higher in summer [August] as compared to winter [February]) since 2017. For example, TCE was detected at an estimated 2.3 micrograms per cubic meter ($\mu g/m^3$) in February 2017, at 51.5 $\mu g/m^3$ in August 2017, at 6.3 $\mu g/m^3$ in February 2018, at 73 $\mu g/m^3$ in August 2018, at 4 $\mu g/m^3$ in February 2019, and at 10 $\mu g/m^3$ during the August 2019 event (Figure 4-1). VOC-impacted groundwater likely provides a continuing source of VOCs to SV at 015-A. Similar fluctuations have also occurred at 018-A between August 2011 and February 2014.

VMPs 079-A and 136-A are near extraction points installed during the system expansion completed in April 2016. August 2019 results show that these locations have had more than a 90% decrease in total VOCs since the SSDS was expanded. Figure 4-2 shows that since August 2016, the summer (August) sampling results at these two points are higher than the winter (February) results, with what appears to be seasonal fluctuation.

VMP 168-A is near the system extraction point SSD-39-A, installed during the third-phase of system expansion completed in July 2017; this location continued to show VOC concentration decreases in August 2019 (TCE at 270 $\mu g/m^3$) as compared to concentrations in August 2018 (TCE at 950 $\mu g/m^3$) and before third-phase expansion in February 2017 (TCE at 22,000 $\mu g/m^3$) (see Table 4-1 and Figure 4-2). However, seasonal variation is also apparent at this point, as the August 2019 VOC concentrations were higher than the concentrations in February 2019.

Concentrations observed after SSDS startup were generally lower than concentrations detected

before the system began operation. VOC reductions at 018-A (in the basement, and last sampled in 2014 due to consistently high groundwater levels) might be more limited than those experienced at main floor VMPs, because the shallow groundwater table (typically less than one foot below the basement slab) possibly impedes vapor flow.

4.1.2 Building C

SV samples collected to date near the Building C SSD system are listed in Table 4-5. These points are within 100 feet of the Building C SSD-system extraction points in the basement; most[3] are within the vacuum influence of SSD-system operations. VMPs 001-C, SSD-4-C (in the southern basement area); and 060-C, 088-C, 113-C, 126-C, 133-C, 141-C 149-C, 152-C, 153-C, and 155-C (in the mid-basement area) were sampled in August 2019 (see Figure 4 in Appendix E).

The highest TCE concentrations in Building C were observed at VMPs 001-C, SSD-4-C, 060-C, 113-C, and 133-C before SSDS extraction began in those areas. The most recent concentrations are summarized in Table 4-6. August 2019 TCE concentrations are lower than the concentrations measured before SSD-system startup and are apparently reaching asymptotic levels after several years of vapor extraction in the area. The August 2019 TCE concentrations at VMPs 001-C, 060-C, 088-C, 113-C, 126-C[4], 133-C, 141-C, 149-C, 153-C, and 155-C were similar to the concentrations measured in the previous semiannual event (February 2019). TCE concentrations were higher at SSD-4-C (160 µg/m^3) and 152-C (150 µg/m^3) in August 2019 as compared to February 2019 concentrations (0.55 µg/m^3 and 49 µg/m^3, respectively) likely due to seasonal variation. Historical concentrations are presented in Table 4-2 and Figure 4-3.

Concentrations of vinyl chloride (VC) observed at 126-C (north of the SSDS extraction points) have also decreased since the SSD-system expansion (see Figure 4-4), but, as shown on Figure 4-4, VC concentrations in sub-slab vapor at 126-C have varied over time with what appears to be seasonal fluctuation; summer (August) sampling results are higher than the winter (February) results. VC has not been detected in SSDS influent samples or in groundwater samples collected from a nearby well pair (MW-88A/B).

[3]Locations 001-C, SSD-4-C, 060-C, 113-C, 127-C, 133-C, 135-C, 149-C, 152-C, 153-C, 155-C, and 156-C
[4]The laboratory results for 126-C and 149-C were erroneously switched by the laboratory.

4.2 SUB-SLAB VAPOR EXTRACTION POINTS

The Building A and Building C SV extraction points are not sampled as part of the semi-annual SSDS monitoring program, because the combined influent for the Building A system is sampled monthly, and the Building C system is sampled every two months (influent sampling results are presented in Section 4.4). Figure 2 in Appendix E shows the Building A extraction points (North, South, Basement North, and Basement South), horizontal extraction laterals, extraction pipe from basement sump HRS-5, and vertical extraction points in Building A (SSD-34-A, SSD-35-A, SSD-36-A, SSD-37-A, SSD-38-A, and SSD-39-A). Figure 4 in Appendix E shows the vertical extraction points in Building C: SSD-21-C, SSD-23-C, SSD-26-C, SSD-27-C, SSD-28-C, SSD-29-C, SSD-30-C, SSD-31-C, SSD-32-C, SSD-33-C, and SSD-34-C.

4.3 VACUUM INFLUENCE

Induced vacuum levels of target-area sub-slab VMPs over time are shown on the following figures in Appendix E: Figure 6 (Building A lay-up room and basement), Figure 7 (Building A eastern area), Figure 8 (Building C southern basement area), and Figure 9 (Building C mid-basement area). Representative vacuum measurements from the September 23, 2019 monitoring episode are indicated on plan views on Figures 10, 11, 12, and 13 of Appendix E. Vacuum influence associated with SSDS VMPs is checked biweekly. The target vacuum is 0.01 inches of water column or greater. (Note: negative vacuums at some points indicate pressure readings that are considered not influenced by the SSDS; pressure readings are likely due to undetermined local features.)

As indicated in the September 2019 progress report (Appendix E), extraction trenches near the Building A lay-up room induce a vacuum equal to or greater than 0.01 inches water column over an approximately 5,900-square-foot area; this area encompasses all SV monitoring points that had elevated VOC concentrations before system startup. The trenches in the Building A basement induce a vacuum over an approximately 2,000-square-foot area that encompasses three of the four VMPs used to measure the SSDS induced vacuum in the basement. The extraction wells in the eastern area of Building A induce a vacuum over an approximately 6,100-square-foot-area and encompass nine of 15 VMPs used to measure the SSDS induced vacuum in that area. Extraction point SSD-39-A in the western area of Building A is inducing vacuum at two nearby VMPs; the associated area of induced vacuum influence is approximately 880 square feet.

The Building C basement extraction wells induce vacuum influence over an approximately 3,800-square-foot area in the southern end of the basement, while the extraction wells in the mid-basement area induce vacuum influence over an approximately 32,900-square-foot area. In the mid-basement, 14 of 20 accessible monitoring points are within the target area shown to have vacuum influence.

SSD systems are performing as designed except for a lack of induced vacuum near SSD-136-A in the eastern area of Building A, as indicated by the lack of influence seen at 136-A-N and 162-A. However, TCE concentrations at 136-A and 136-A-N have both decreased more than 98% since the system was expanded in 2016.

4.4 INFLUENT-VAPOR SAMPLES

Influent-vapor samples are collected monthly to monitor the Building A SSDS operation, and once every two months to monitor the Building C SSDS operation. VOC concentrations at the granular activated-carbon (GAC) influent, midpoint (after the lead drum), and effluent (after the second drum) points are monitored to determine when the midpoint concentration reaches 50% of the influent; when the 50% breakthrough is reached, or at Tetra Tech's discretion with concurrence from Lockheed Martin Corporation (Lockheed Martin), the lead GAC drum is changed out. These samples also allow monitoring of influent-concentration trends over time. Samples are collected directly from all three sampling ports of both SSD systems by connecting a clean one-liter Summa® canister (batch certified) to the Teflon® tubing of each sampling port and opening the valve for approximately one minute. The samples were submitted to TestAmerica Laboratories, Inc. (TestAmerica) in Knoxville, Tennessee for VOC analysis using United States Environmental Protection Agency (USEPA) Toxic Organic Method (TO-15).

Tables 4-7A and 4-7B summarize the influent-vapor concentrations of target VOCs in samples over time (from system startup in March 2008 through August 2019). These results are displayed graphically on Figures 14 and 15 in Appendix E. Tables 4-7A and 4-7B also provide average influent concentrations for the current (April–September 2019) and previous (October 2018–March 2019) six-month reporting periods. The six-month average-influent (total) VOC concentration during the current reporting period is slightly lower than the average-influent VOC

concentration during the previous semiannual reporting period in Building A (1,373 µg/m^3 versus 1,429 µg/m^3) and slightly higher in Building C (73 µg/m^3 versus 49 µg/m^3). Overall, influent VOC concentrations for both SSD-systems have been relatively stable or slowly decreasing since 2009 (see Figures 14 and 15 in Appendix E).

The goal of the SSD systems is to maintain a negative pressure below the slab (relative to the room space), thus minimizing VOC migration from the sub-slab soil into indoor air. VOC mass removal occurs by treatment of the vapor drawn out to maintain the vacuum.

VOC removal rates for SSDS influent mass in Building A ranged from 0.02 to 0.05 pounds per day (lbs/day); these rates are slightly lower than the removal rates observed in the previous semiannual reporting period (0.04 to 0.07 lbs/day). The Building A system has removed eight pounds (lbs) of VOCs during this reporting period, eight pounds during the previous reporting period, and has removed approximately 198 lbs since system startup in March 2008.

The VOC removal rate in Building C during the current reporting period was slightly higher than the previous reporting period, approximately 0.03 pounds per month (lbs/month) compared to 0.02 lbs/month. The Building C SSDS has removed 0.18 lbs of VOCs this reporting period, 0.12 lbs during the previous reporting period, and has removed 12.4 lbs since system startup in March 2008.

4.5 SYSTEM PERFORMANCE

In general, flow rates and induced vacuums for the SSD systems are performing as designed except for a lack of induced vacuum near SSD-136-A in the eastern area of Building A. We will continue to monitor system induced vacuum performance; however, some localized areas are likely to remain not amenable to induced vacuum, due to the heterogeneous structure of subsurface soil and water accumulation in the subsurface of these older structures. The induced-vacuum influence of the Building A system is over 5,900 square-feet on the main floor (encompassing the lay-up room), 2,000 square-feet in the basement, 6,100 square-feet in the northern and eastern areas, and 880 square feet in the western area. The induced-vacuum influence of the Building C SSDS extends over an approximately 3,800 square-foot area in the southern basement, and over approximately 32,900 square-feet in the mid-basement area.

SECTION 5
CONCLUSIONS

5.1 CONCLUSIONS

Tetra Tech, Inc., (Tetra Tech) has completed Round 27 of vapor-intrusion (VI) monitoring (the second of two scheduled in 2019) in Buildings A, B, and C at the Middle River Complex (MRC) (owned by LMC Properties, Inc.) in Middle River, Maryland. This ongoing investigation seeks to evaluate whether volatile organic compounds (VOCs) in sub-slab vapor (associated with soil and groundwater chemicals of concern [COC] at the site) might be moving into indoor air (IA) at the Middle River Complex facilities, and whether subsurface vapor contamination remains present at concentrations that dictate continued operation of the sub-slab-depressurization (SSD) vapor-intrusion-mitigation systems (or if a transition/exit strategy can be performed). The data set is composed of indoor air and sub-slab vapor (SV) samples collected in August 2019. Ambient air samples were also collected at four outdoor background locations around the perimeter of the Middle River Complex. Indoor air samples collected following the Building A sub-slab-depressurization shutdown event are also discussed separately from the Round 27 data. All data were validated to ensure compliance with analytical method requirements.

Indoor air data were compared to risk-based screening levels for industrial air set at the 1×10^{-5} (i.e., one-in-100,000 probability) risk level for carcinogens, or at a hazard quotient of 1 for noncarcinogens (as published in the United States Environmental Protection Agency [USEPA] *Regional Screening Levels for Chemical Contaminants at Superfund Sites* [USEPA, 2019]). For samples collected in the Building A basement only, indoor air levels of trichloroethene (TCE) were compared to a Maryland Department of the Environment-approved basement-specific screening level of 35 micrograms per cubic meter ($\mu g/m^3$), based on the limited exposure potential for workers entering the basement. Indoor air samples were also compared to federal Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs). Alternate values, such as the "Threshold Limit Values" published by the American Council of Governmental

Industrial Hygienists, were used for chemicals without published permissible exposure limits. SV data were compared to screening values derived using methods described in *OSWER Technical Guide for Assessing and Mitigating the Vapor Intrusion Pathway from Subsurface Sources to Indoor Air* (USEPA, 2015) by applying an attenuation factor of 0.03 to the indoor-air screening values.

Historically, trichloroethene and naphthalene have been the prevalent contaminants of concern in indoor air at this site. In Round 27, trichloroethene was not detected in indoor air in Building B, but was detected in indoor air in Buildings A and C. Trichloroethene was detected in eight of 35 indoor air samples collected during Round 27. Only one indoor air trichloroethene detection at a location in the Building A basement was greater than the (unadjusted for the basement) MDE screening level of 8.8 $\mu g/m^3$ (see plan view in Figure 5-1), but this concentration was less than the Building A basement-specific screening level (35 $\mu g/m^3$), and was therefore not an exceedance. The reduced trichloroethene indoor air concentrations in the Building A basement, as compared to previous years, are attributable to sealing and extracting vapors from basement sump HRS-5; this sump was connected to the Building A sub-slab-depressurization system in June 2017.

In Round 27, naphthalene was detected in only one of 35 indoor air samples at a concentration (4.3 $\mu g/m^3$) that exceeded its screening level (3.6 $\mu g/m^3$). This sole naphthalene detection occurred in a duplicate sample (location 018-A) in Building A; naphthalene was not detected in the corresponding parent sample. Sub-slab vapor naphthalene was detected in six of 33 samples. The maximum naphthalene sub-slab vapor concentration (detected in a duplicate sample at location 102-C) was approximately equal to the screening level (120 $\mu g/m^3$). The sub-slab vapor naphthalene concentration in the corresponding parent sample (77 $\mu g/m^3$) was less than the screening level. Naphthalene was not detected in indoor air in Buildings B or C.

5.1.1 Building A

Trichloroethene exceeded its screening level in sub-slab vapor during Round 27. Trichloroethene concentrations detected in Building A indoor air and sub-slab vapor are summarized below.

Basement

- Trichloroethene was detected in indoor air at all four Building A basement sampling locations, but at concentrations less than its basement-specific screening level (35 µg/m^3), which was derived to account for reduced potential exposure in the basement. At one of the basement locations (093-A), the indoor air trichloroethene concentration was greater than its (unadjusted for the basement) industrial worker screening level (8.8 µg/m^3). Historical indoor-air trichloroethene concentrations in the Building A basement samples have never exceeded the basement-specific screening level but have exceeded the industrial screening level.

- Trichloroethene was detected at concentrations greater than the sub-slab vapor screening level (293 µg/m^3) in vapor samples collected from behind the eastern basement wall at locations 170-A, 171-A, and 173-A, as well as in a sample collected from the Building A basement floor at location 174-A. Direct measurement of air above the sumps and of air trapped in the covered sumps indicates that the sumps and drains in the Building A basement are the sources of the trichloroethene.

- Information gained from the January–May 2018 studies was used to determine constructible, cost-effective solutions that control water and vapor accumulation in Building A basement sumps (Tetra Tech, 2018e). Mitigation strategies have been proposed and were subsequently approved by Maryland Department of the Environment (MDE) (Tetra Tech, 2019), and will be implemented starting (in December 2019) with the abandonment of sump HRS-5. Two additional sumps (HRS-6 and HRS-7) in the southern portion of Building A basement will be abandoned after they are monitored for unintended consequences (e.g., potential flooding of the basement). There are no plans for mitigation of sumps SP1/SP1A and the utility corridor sump.

Main floor

- A trichloroethene exceedance (420 µg/m^3) of its screening level (293 µg/m^3) was detected in sub-slab vapor at location 118-A in the bond layup room east of the former plating shop on the main floor, and at 136-A (500 µg/m^3) in the eastern area of Building A. Sample 118-A was collected where a positive-pressure air-conditioning system was operating. This sampling location is near the radii of influence of the sub-slab depressurization systems. Location 136-A is also located near the radii of influence of the SSD system. Indoor air concentrations of trichloroethene on the main floor of Building A were all less than the screening level.

The sub-slab-depressurization system in Building A appears to be operating as designed (except for limited vacuum influence in the SSD-136-A area) and appears to be effectively mitigating sub-slab vapor intrusion from known source areas of sub-slab vapor contamination, in concert with the indoor-air filtration units and control of vapor emissions from the sumps. Contaminants are constantly removed from soil vapor during system operation, and indoor air concentrations in the

main part of Building A (excluding the basement) rarely exceed screening values. Filter cartridges are changed-out quarterly; no other maintenance is required.

The Building A sub-slab-depressurization system was discovered offline during the September 23, 2019 system check. According to the system's hour counter reading taken at that time, it had not been operating since September 11, 2019 (or for at least 12 days). Resampling of seven indoor air locations within or close to the radius of influence of the Building A system (i.e., locations 015-A, 018-A, 021-A, 079-A, 117-A, 136-A, and 168-A) took place on October 2, 2019. Only one indoor air exceedance (naphthalene at 9.2 $\mu g/m^3$ [location 018-A]) of its indoor air screening level (3.6 $\mu g/m^3$) was detected. (Note that a naphthalene exceedance (4.3 $\mu g/m^3$) was also noted at the same location [018-A] in August 2019.) All other indoor air results collected from Building A following the unscheduled 12-day system shutdown were less than applicable screening levels.

Although basement occupancy is restricted, and screening levels related to restricted occupancy are not exceeded, this area will continue to be monitored as the sub-slab-depressurization system continues to operate. Figures 5-2A, 5-2B, and 5-2C show concentrations of trichloroethene and naphthalene in Building A in sub-slab vapor samples, in indoor air of the basement, and in indoor air on the first floor of the building (respectively). Direct measurement of air above the sumps and of air trapped in the covered sumps historically has indicated that the sumps and drains in the Building A basement have been the primary trichloroethene sources. Mitigation efforts including the abandonment of select sumps (HRS-5, HRS-6, and HRS-7) in the southern portion of the basement will be initiated in December 2019.

5.1.2 Building B

No exceedances were noted in the Building B indoor air or sub-slab vapor samples during Round 27. The most recent exceedance of the indoor air screening level was during Round 18, when one slight exceedance of naphthalene was detected (February 2015).

5.1.3 Building C

Trichloroethene was detected at concentrations below its screening level in three of 18 indoor air samples collected from Building C during Round 27. Sub-slab vapor exceedances of

trichloroethene (at concentrations ranging from 330 µg/m^3 to 1,200 µg/m^3) were detected at four locations in Round 27: at 060-C, in the east-central portion of Building C, and within the system's radius of influence; at 102-C, in the central portion of Building C near the former Patriot plating line and outside of the radius of influence of the Building C system; at 133-C, in the central portion of Building C, north of the former Patriot plating line, and within in the system's radius of influence; and at 141-C, south of the museum room and north of the machine shop, in the northeastern portion of Building C, within the radius of influence of the Building C system. These Round 27 exceedances in sub-slab vapor are consistent with those observed in other recent sampling rounds (e.g., Rounds 21 through 26).

Vinyl chloride was detected in sub-slab vapor at location 149-C at a concentration (2,700 µg/m^3) greater than its screening level (933 µg/m^3) during Round 27. However, during previous sampling (Rounds 18 through 26), vinyl chloride exceedances in sub-slab vapor have occurred at location 126-C and not at 149-C, indicating that sub-slab vapor results reported for these two sampling locations (126-C and 149-C) during Round 27 may have been swapped. Locations 126-C and 149-C are near each other in the northern portion of the Building C basement. Concentrations of vinyl chloride in sub-slab vapor at 126-C have decreased since the sub-slab depressurization system expansion, but have fluctuated over time. Vinyl chloride has not been detected in groundwater near 126-C, nor in indoor air, despite the presence of trichloroethene in nearby groundwater monitoring well MW-88A at concentrations up to 1,500 micrograms per liter (µg/L) in 2009.

Sub-slab vapor concentrations of 1,1-dichloroethane (2,900 µg/m^3 and 3,800 µg/m^3 in parent and duplicate samples, respectively) exceeded its screening level (2,567 µg/m^3) at location 102-C during Round 27. The maximum sub-slab vapor detection of naphthalene (120 µg/m^3 in a duplicate sample at location 102-C) was equal to (but did not exceed) its screening level during Round 27; the corresponding parent sample concentration (77 µg/m^3) was less than the screening level (120 µg/m^3). Sub-slab vapor concentrations of 1,1-dichloroethane and naphthalene exceeded their screening levels at location 102-C during other recent sampling rounds (e.g., Rounds 17, 18, 20, 22, 23, 24, 25, and 26). The sub-slab vapor concentrations of naphthalene and 1,1-dichloroethane in Building C do not appear to impact indoor air concentrations, as these analytes were either not

detected in indoor air or were detected at concentrations less than indoor air screening levels during previous sampling rounds.

In general, sub-slab vapor concentrations of volatile organic compounds have decreased in the southern basement area (SSD-4-C) of Building C since system startup in March 2008. Vapor monitoring points (060-C, 088-C, 113-C, 126-C, 133-C, and 135-C) in the mid-basement area also show lower concentrations, as compared to results before system expansion in May 2013.

The absence of any Building C indoor air screening-level exceedances for any compound suggests that vapor intrusion is likely not occurring. The sub-slab-depressurization system in Building C appears to be operating as designed, and appears to be effectively mitigating sub-slab vapor intrusion from known source areas of sub-slab vapor contamination. Figures 5-3A and 5-3B show Round 27 sub-slab vapor and indoor air concentrations (respectively) of 1,1-dichororethane, trichloroethene, and vinyl chloride in Building C.

- October 2019 Sampling Locations
- Sump or Sump Pit
- SSD Radius of Influence
- Buildings A, B and C
- Building A Basement
- Building B and C Basement
- Excavation Area
- SSD Treatment Unit

All results in microgram(s) per cubic meter (µg/m^3).

X - moved from original location once.

Screening Levels Exceeded

Chemical	Indoor Air	Soil Vapor
Naphthalene	3.6	NA

NA – Not applicable

IA - Indoor Air
SSD - Sub-slab Depressurization
SV - Soil Vapor
TCE - Trichloroethene

August 2019 Sub-Slab Vapor TCE Concentration

- 10000 ug/m3
- 1000 ug/m3
- 293 ug/m3
- 0.1 ug/m3

TRICHLOROETHENE SAMPLING RESULTS ROUND 27 BUILDINGS A, B AND C

Legend

- IA, 1st Floor
- IA, Basement
- SV
- SSD Treatment Unit
- SSD Radius of Influence
- Buildings A, B and C
- Building B and C Basement
- Tunnel
- NA — Indicates no indoor air results were collected.
- NA — Indicates no soil vapor results were collected.

(1) Historical data concentrations indicate that SV results at locations 126-C and 149-C may have been swapped during Round 27. Results are presented as reported by the laboratory (i.e., the data were not altered to account for this).

All units in µg/m^3.
All location IDs begin with "AIR-."
DUP - Duplicate sample. IA - Indoor air.
J = Estimated value. NA - Not applicable.
SSD = Sub-slab Depressurization. SV - Sub-slab vapor.
TCE - Trichloroethene. U - Not detected.

ug/m3 - microgram per cubic meter.
X - moved from original location once.
XX - moved from original location twice.
Indoor air quality results shown in blue type.
Soil vapor results shown in green type.
Exceedances labeled in ***bold italicized*** print.

A shaded maximum background value indicates that the maximum detected value from the site data exceeds the maximum background value.

A bolded chemical name/criterion indicates that its concentration exceeds background and the industrial air RSL based on an HQ of 0.1 or an ILCR of 1×10^{-6} (i.e., one-tenth of screening value listed).

A bolded/shaded chemical name/criterion indicates that its concentration exceeds background and the industrial air RSL based on an HQ of 1 or an ILCR of 1×10^{-5} (i.e., the screening value presented).

Footnotes:

1 - Sample and duplicate are considered two separate samples when determining the minimum and maximum concentrations but are considered one sample when determining frequency of detection, average, standard deviation, and the number of samples exceeding screening criteria.

2 - Values presented are sample-specific quantitation limits.

3 - One-half the detection limit was used to represent non-detected results in calculating the average of all results and the standard deviation.

4 - Exceedance counts are based on detected results only.

5 - USEPA Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites, May 2019. RSLs for carcinogens were adjusted to be based on a lifetime cancer risk of 1E-05. RSLs for noncarcinogens were not adjusted and represent a hazard quotient (HQ) of 1.

6 - Occupational Safety and Health Administration (OSHA) Permissible Exposure Limit (PEL).

Definitions:

ca = screening value based on 1×10^{-5} carcinogenic risk

HQ - hazard quotient

ILCR - incremental lifetime cancer risk

J - estimated value

µg/m^3 - micrograms per cubic meter

N = National Institute for Occupational Safety and Health Recommended Exposure Limit

NA - not applicable/not available

nc = noncarcinogenic screening values based on noncarcinogenic hazard quotient = 1

ND - not detected

OSHA - Occupational Safety and Health Administration

PEL - permissable exposure limit

RSL - regional screening level

USEPA - United States Environmental Protection Agency

A bolded chemical name/criterion indicates that the maximum concentration exceeds the industrial air RSL divided by 0.03 based on an HQ of 0.1 or an ILCR of 1×10^{-6} (i.e., one-tenth the screening value presented).

A bolded/shaded chemical name/criterion indicates that the maximum concentration exceeds the industrial air RSL divided by 0.03 based on an HQ of 1 or an ILCR of 1×10^{-5} (i.e., the screening value presented).

Footnotes:

1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations, but are considered one sample when determining frequency of detection, average, standard deviation, and the number of samples exceeding criteria.

2 - Historical data concentrations indicate that sub-slab vapor results at locations 126-C and 149-C may have been swapped during Round 27. Results are presented as reported by the laboratory (i.e., the data were not altered to account for this).

3 - Values presented are sample-specific quantitation limits.

4 - One-half the detection limit was used to represent non-detected results in calculating the average of all results and the standard deviation.

5 - Screening values derived in accordance with Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (November 2002). Screening values are equal to United States Environmental Protection Agency (USEPA) Industrial Air Screening Values divided by an attenuation factor 0.03, and correspond to a target cancer risk level of 1.0E-05 or a hazard quotient (HQ) of 1.

6 - Exceedance counts are based on detected results only.

Definitions:

-- = no criterion available

ca = screening value based on carcinogenic effects

HQ = hazard quotient

ILCR = incremental lifetime cancer risk

J = estimated value

NA = not available

nc = screening value based on noncarcinogenic effects

RSL = regional screening level

All results are in µg/m³.

(1) The original sample and duplicate are considered as two separate samples when determining the minimum and maximum concentration and as one sample when determining the frequency of detection.

(2) Values presented are sample-specific quantitation limits.

(3) The average of the original sample and duplicate is used for determining the average of all values, average of detected values, and 95% UCL.

(4) One-half the detection limit was used to represent non-detected results in calculating the average of all results.

(5) Value is the non-carcinogenic industrial air regional screening level corresponding to HQ = 1 (USEPA, May 2019).

(6) Field duplicate pair samples are counted as one sample in determining the number of samples exceeding the screening level. The field duplicate pair is considered to exceed the screening level if either the original or duplicate sample is greater than the screening level.

(7) The maximum detected concentration (36 µg/m³) was detected in a duplicate sample, and the corresponding original sample concentration (0.75 µg/m³) is considerably less than the maximum concentration. Resampling at the same location found concentrations that were closer to the original sample concentration.

(8) There are less than five samples; therefore, a UCL is not presented.

(9) There are less than three detections; therefore, a UCL is not presented.

(10) There are no trichloroethene results for the Building B basement from the February 2019 sampling event.

(11) There are no trichloroethene results for the Building C first floor.

Definitions:

HQ - hazard quotient
J - estimated value
µg/m³ - micrograms per cubic meter
NA - not applicable/not available
UCL - upper confidence limit
USEPA - United States Environmental Protection Agency

All results are in µg/m^3.

(1) The original sample and duplicate are considered as two separate samples when determining the minimum and maximum concentration and as one sample when determining the frequency of detection.

(2) Values presented are sample-specific quantitation limits.

(3) The average of the original sample and duplicate is used for determining the average of all values, average of detected values, and 95% UCL.

(4) One-half the detection limit was used to represent non-detected results in calculating the average of all results.

(5) Value is the carcinogenic industrial air regional screening level corresponding to 1×10^{-5} risk level (USEPA, May 2019).

(6) Field duplicate pair samples are counted as one sample in determining the number of samples exceeding the screening level. The field duplicate pair is considered to exceed the screening level if either the original or duplicate sample is greater than the screening level.

(7) There are less than three detections; therefore, a UCL is not presented.

(8) There are less than five samples; therefore, a UCL is not presented.

(9) There are no naphthalene results for the Building C first floor from historical or February 2019 sampling events.

Definitions:

HQ - hazard quotient

ILCR - incremental lifetime cancer risk

J - estimated value

µg/m^3 - micrograms per cubic meter

UCL - upper confidence limit

USEPA - United States Environmental Protection Agency

A benchmark of 3.6 µg/m^3 corresponds to ILCR = 1×10^{-5}.

Shaded cells indicate a concentration greater than the risk-based screening level.

Bolded cells indicate that the analyte is detected in the sample.

1-This location is in the basement, where the TCE screening level is 35 µg/m^3 (not 8.8 µg/m^3); and therefore not an exceedance.
The higher TCE screening level is based on reduced exposure potential to basement air, and was approved by MDE in 2017.

Shaded cells indicate a concentration greater than the risk-based screening level.

Bolded cells indicate that the analyte is detected in the sample.

1-This location is in the basement, where the TCE screening level is 35 µg/m^3 (not 8.8 µg/m^3); and therefore not an exceedance.
The higher TCE screening level is based on reduced exposure potential to basement air, and was approved by MDE in 2017.

Industrial Air Screening Levels from USEPA RSLs for Chemical Contaminants at Superfund Sites, May 2019
ca =carcinogenic screening values based on 1×10^{-5} carcinogenic risk
nc = noncarcinogenic screening values based on noncarcinogenic hazard quotient = 1

-- = not available
A = American Council of Governmental Industrial Hygenists Theshold Limit Value
J = estimated value
MDE = Maryland Department of the Environment

VINYL CHLORIDE	933	ca	0.33 U	0.33 U

Notes: All sample concentrations are in micrograms per cubic meter (µg/m^3)

Shaded cells indicate a concentration greater than risk-based screening level.

Bolded cells indicate that the analyte is detected in the sample.

1 - Screening values derived in accordance with Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (November 2002). Screening values are equal to United States Environmental Protection Agency (USEPA) Industrial Air Screening Values divided by an attenuation factor of 0.03, and correspond to a target cancer risk level of 1×10^{-5}.

-- = not available

ca = screening value based on carcinogenic effects

J = estimated value

nc = screening value based on noncarcinogenic effects

U = nondetect

Notes: All sample concentrations are in micrograms per cubic meter (µg/m^3)
Shaded cells indicate a concentration greater than risk-based screening level.
Bolded cells indicate that the analyte is detected in the sample.

1-Screening values derived in accordance with Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (November 2002). Screening values are equal to United States Environmental Protection Agency (USEPA) Industrial Air Screening Values divided by an attenuation factor of 0.3, and correspond to a target cancer risk level of 1×10^{-5}.
2 - Historical data concentrations indicate that sub-slab vapor results at locations 126-C and 149-C may have been swapped during Round 27. Results are presented as reported by the laboratory (i.e., the data were not altered to account for this).

-- = not available
ca = screening value based on carcinogenic effects
J = estimated value
nc = screening value based on noncarcinogenic effects
U = nondetect
UJ = non-detected value is estimated

All concentrations are in micrograms per cubic meter air ($\mu g/m^3$).

Shaded cells indicate a concentration greater than the risk-based screening level.

Bolded cells indicate analyte was detetected in background sample(s).

Industrial Air Screening Levels from USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, May 2019

-- = not available

A = American Council of Governmental Industrial Hygienists Theshold Limit Value

ca = screening value based on 1×10^{-5} carcinogenic risk

J = estimated value

N = National Institute for Occupational Safety and Health Recommended Exposure Limit

nc = screening value based on noncarcinogenic hazard quotient = 1

OSHA PEL = Occupational Safety and Health Administration Pemissible Exposure Limit

U = not detected

USEPA = United States Environmental Protection Agency

TABLE 3-12

ANALYTE CONCENTRATIONS IN BACKGROUND AIR SAMPLES COMPARED TO INDOOR AIR SAMPLES - AUGUST 2019 LOCKHEED MARTIN CORPORATION MIDDLE RIVER COMPLEX MIDDLE RIVER, MARYLAND

Analyte	Maximum Background Concentration ($\mu g/m^3$)	Maximum Indoor Air Sample Concentration ($\mu g/m^3$)[1]	Number of Indoor Air Samples with Detects[1]	Number of Indoor Air Detects < Background[1][2]	Number of Indoor Air Detects = Background[1][2]	Number of Indoor Air Detects > Background[1][2]
BENZENE	0.58	0.74	32	26	2	4
CARBON TETRACHLORIDE	0.5	0.59	32	27	1	4
CHLORODIFLUOROMETHANE	1.8	38	33	15	0	18
CHLOROFORM	0.21	0.89	32	3	1	28
DICHLORODIFLUOROMETHANE	1.9	2.9	34	8	3	23
ETHYLBENZENE	0.3	3.7	31	0	0	31
METHYLENE CHLORIDE	10	340	26	10	0	16
TOLUENE	3.6	150	33	10	0	23
TOTAL XYLENES	1.4	15	33	2	0	31

1 - The original sample and duplicate are considered as two separate samples when determining the minimum and maximum concentration, but are considered one sample when determining the number of samples with detects and the number of samples less than, equal to, or greater than background.

2 - If one sample in a duplicate pair was greater/equal to background and the other sample in the duplicate pair was less than background, the maximum detected concentration in the field duplicate pair was used to represent the field duplicate pair.

Four background samples and 35 indoor air samples were analyzed in Round 27.

Shaded cells indicate a concentration greater than the risk-based screening level.

Bolded cells indicate that the analyte is detected in the sample.

*This location is in the basement. The TCE screening level for basement samples is 35 ug/m^3 based on reduced exposure potential in the basement. The screening level was approved by MDE in 2017.

-- = not available

A = American Council of Governmental Industrial Hygenists Theshold Limit Value

J = estimated value

MDE = Maryland Department of the Environment

N = National Institute for Occupational Safety and Health Recommended Exposure Limit

Industrial Air Screening Levels from USEPA RSLs for Chemical Contaminants at Superfund Sites, May 2019

ca =carcinogenic screening values based on 1×10^{-5} carcinogenic risk

nc = noncarcinogenic screening values based on noncarcinogenic hazard quotient = 1

OSHA PEL = Occupational Safety and Health Administration Pemissible Exposure Limit

RSLs= Regional Screening Levels

U = not detected

Notes:

Data presented in this table is from sub-slab vapor samples.

VOC = volatile organic compound
SSDS = sub-slab depressurization system
µg/m^3 = micrograms per cubic meter
- = not detected (below reporting limit)
N/A = compound not reported
N/S = not sampled

J = estimated value
J+ = estimated value, may be biased high
K = value is biased high
NS = not sampled
N/A = sampling data for this location not previously included in this table

Note: Sample at location 141-C was collected in September 2013 rather than August 2013.

Note: The August 2019 results for 149-C were mistakenly switched by the laboratory with the results for 126-C. The results in this table are the results believed to correspond to 126-C and 149-C.

Notes:
Data presented in this table is from sub-slab vapor samples.
µg/m^3 = micrograms per cubic meter
- = not detected (below reporting limit)
DL = diluted analysis
NA = compound not reported
NS = not sampled
NA = compound not reported
K = value is biased high
L = value is biased low
VOC = volatile organic compound
SSDS = sub-slab depressurization system

Notes:
- —point(s) not sampled.
N/A—point may have been sampled but the results were not applicable to the SSD-system.
Points with an “SSD” designation were installed and are monitored for the SSD-system.
Points without the SSD designation are used for the vapor-intrusion monitoring program.

TABLE 4-4

TRICHLOROETHENE CONCENTRATIONS BEFORE AND DURING SSDS OPERATION, BUILDING A
LOCKHEED MARTIN MIDDLE RIVER COMPLEX, MIDDLE RIVER, MARYLAND

Vapor Monitoring Point	*Before SSD-system operation**		*During SSD-system operation (most recent concentration)*	
	Date	*Sub-Slab Vapor Concentration ($\mu g/m^3$)*	*Date*	*Sub-Slab Vapor Concentration ($\mu g/m^3$)*
015 A	April 2007	326,000	August 2019	10
018 A	August 2010	64,000	February 2014	174
079-A	February 2016	3,500	August 2019	150

* value reported is for total xylenes
-- - non-detect (below detection limit)
B - compound was found in the blank and sample
NA - not applicable/not analyzed
NS - not sampled
SSD - sub-slab depressurization
SV - soil vapor
D - duplicate
J - estimated value

MRC AUGUST 2019 Round 27 IA/SV SAMPLE LOG SHEET

Date: August 14, 2019

SAMPLING DATA:

SOIL VAPOR SAMPLE

SV Sample ID:	SV-001-C-27
SV Canister #:	11720
SV Regulator #:	7255
SV Start Time:	9:05 AM
SV Start Pressure:	-30
SV Stop Time:	10:24 AM
SV Stop Pressure:	0

INDOOR AIR QUALITY SAMPLE

IAQ Sample ID:	IA-001-C-27
IAQ Canister #:	09552
IAQ Regulator #:	11669
IAQ Start Time:	7:51 AM
IAQ Start Pressure:	-30
IAQ Stop Time:	4:31 PM
IAQ Stop Pressure:	-4

SAMPLE COLLECTION INFORMATION:

Analysis	Container Requirements	Collected
TO-15	1 Liter and 6 Liter Canisters	☒ Yes ☐ No
		☐ Yes ☐ No
		☐ Yes ☐ No

LOCATION:

OBSERVATIONS / NOTES:

Original can for SV-001 damaged (-1 pressure)

APPENDIX C—LABORATORY ANALYTICAL REPORTS

eurofins | Environment Testing TestAmerica

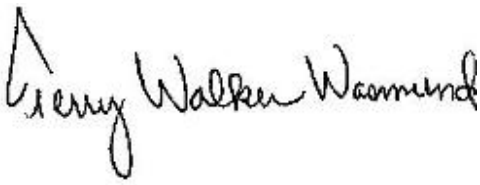
ANALYTICAL REPORT

Job Number: 140-16367-1

Job Description: MMRC SV/IAQ Round 27, MRC, Baltimore, MD

For:
Tetra Tech, Inc.
20251 Century Blvd
Suite 200
Germantown, MD 20874

Attention: Samantha Brenner



Approved for release.
Terry Walker Wasmund
Project Manager II
8/30/2019 2:40 PM

Terry Walker Wasmund, Project Manager II
5815 Middlebrook Pike, Knoxville, TN, 37921
(865)291-3000
terry.wasmund@testamericainc.com
08/30/2019

cc: Ms. Michelle Woeber

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins TestAmerica Project Manager.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Qualifiers

Air - GC/MS VOA

Qualifier	Qualifier Description
*	LCS or LCSD is outside acceptance limits.
B	Compound was found in the blank and sample.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Job Narrative
140-16367-1

Receipt
The samples were received on 8/17/2019 at 10:30 AM. The samples arrived in good condition and properly preserved.

Air - GC/MS VOA - Method TO-15 LL
EPA methods TO-14A and TO-15 specify the use of humidified "zero air" as the blank reagent for canister cleaning, instrument calibration and sample analysis. Ultra-high purity humidified nitrogen from a cryogenic reservoir is used in place of "zero air" by Eurofins TestAmerica Knoxville.

The continuing calibration verification (CCV) associated with batch 140-32704 exhibited % difference of > 30% for Vinyl chloride; however, the results were within the LCS acceptance limits. The EPA method requires that all target analytes in the continuing calibration verification standard be within 30% difference from the initial calibration. According to the laboratory standard operating procedure, the continuing calibration is acceptable if it meets the laboratory control sample acceptance criteria.

Vinyl chloride recovered outside control limits for the LCS associated with analytical batch 140-32704. This is not indicative of a systematic control problem because this was random marginal exceedances. Qualified results have been reported.

Sample IA-075-A-27 (140-16367-16) was diluted due to the abundance of non-target analytes. Elevated reporting limits (RLs) are provided.

Can Certification Comments:
Due to the large number of analytes in the CCV, there is a high probability that one or more analytes will recover outside acceptance limits. The laboratory's SOP allows for several analytes to recover outside criteria for this method when analyzing for a full list. The CCV associated with the can cleaning batches had analytes outside control limits. These results have been reported and qualified

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Comments
No additional comments.

Summa Canister Dilution Worksheet

Client: Tetra Tech, Inc.

Job No.: 140-16367-1

Lab Sample ID	Canister Volume (L)	Preadjusted Pressure ("Hg)	Preadjusted Pressure (atm)	Preadjusted Volume (L)	Adjusted Pressure (psig)	Adjusted Pressure (atm)	Adjusted Volume (L)	Initial Volume (mL)	Dilution Factor	Final Dilution Factor	Date	Analyst
140-16367-3	1	-12.2	0.59	0.59	3.1	1.21	1.21		2.04	2.04	08/17/19 15:08	Knight, Benjamin K

Formulae:

Preadjusted Volume (L) = (Preadjusted Pressure ("Hg) + 29.92 "Hg * Vol L) / 29.92 "Hg

Adjusted Volume (L) = (Adjusted Pressure (psig) + 14.7 psig * Vol L) / 14.7 psig

Dilution Factor = Adjusted Volume (L) / Preadjusted Volume (L)

Where:

29.92 "Hg = Standard atmospheric pressure in inches of Mercury (“Hg)

14.7 psig = Standard atmospheric pressure in pounds per square inch gauge (psig)

EUROFINS/TESTAMERICA KNOXVILLE SAMPLE RECEIPT/CONDITION UPON RECEIPT ANOMALY CHECKLIST **Log In Number:** **16367**

Review Items	Yes	No	NA	If No, what was the problem?
1. Are the shipping containers intact?	/			☐ **Containers, Broken**
2. Were ambient air containers received intact?			/	☑ Checked in lab
3. The coolers/containers custody seal if present, is it intact?	/			☐ Yes ☐ NA
4. Is the cooler temperature within limits? (> freezing temp. of water to 6 °C, VOST: 10°C) Thermometer ID :_____ Correction factor: _____			/	☐ **Cooler Out of Temp, Client Contacted, Proceed/Cancel** ☐ **Cooler Out of Temp, Same Day Receipt**
5. Were all of the sample containers received intact?	/			☐ **Containers, Broken**
6. Were samples received in appropriate containers?	/			☐ **Containers, Improper; Client Contacted; Proceed/Cancel**
7. Do sample container labels match COC? (IDs, Dates, Times)	/			☐ **COC & Samples Do Not Match** ☐ **COC Incorrect/Incomplete** ☐ **COC Not Received**
8. Were all of the samples listed on the COC received?	/			☐ **Sample Received, Not on COC** ☐ **Sample on COC, Not Received**
9. Is the date/time of sample collection noted?	/			☐ **COC; No Date/Time; Client Contacted**
10. Was the sampler identified on the COC?	/			☐ **Sampler Not Listed on COC**
11. Is the client and project name/# identified?	/			☐ **COC Incorrect/Incomplete**
12. Are tests/parameters listed for each sample?	/			☐ **COC No tests on COC**
13. Is the matrix of the samples noted?	/			☐ **COC Incorrect/Incomplete**
14. Was COC relinquished? (Signed/Dated/Timed)	/			☐ **COC Incorrect/Incomplete**
15. Were samples received within holding time?	/			☐ **Holding Time - Receipt**
16. Were samples received with correct chemical preservative (excluding Encore)?			/	☐ **pH Adjusted, pH Included (See box 16A)** ☐ **Incorrect Preservative**
17. Were VOA samples received without headspace?			/	☐ **Headspace (VOA only)**
18. Did you check for residual chlorine, if necessary? (e.g. 1613B, 1668) Chlorine test strip lot number:_____			/	☐ **Residual Chlorine**
19. For 1613B water samples is pH<9?			/	☐ If no, notify lab to adjust
20. For rad samples was sample activity info. Provided?			/	☐ Project missing info

Definitions/Glossary

Client: Tetra Tech, Inc. Job ID: 140-16367-1
Project/Site: MMRC SV/IAQ Round 27, MRC, Baltimore, MD

Qualifiers

Air - GC/MS VOA

Qualifier	Qualifier Description
*	LCS or LCSD is outside acceptance limits.
B	Compound was found in the blank and sample.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
PQL	Practical Quantitation Limit
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)

Job Narrative
140-16367-1

Receipt
The samples were received on 8/17/2019 at 10:30 AM. The samples arrived in good condition and properly preserved.

Air - GC/MS VOA - Method TO-15 LL
EPA methods TO-14A and TO-15 specify the use of humidified "zero air" as the blank reagent for canister cleaning, instrument calibration and sample analysis. Ultra-high purity humidified nitrogen from a cryogenic reservoir is used in place of "zero air" by Eurofins TestAmerica Knoxville.

The continuing calibration verification (CCV) associated with batch 140-32704 exhibited % difference of > 30% for Vinyl chloride; however, the results were within the LCS acceptance limits. The EPA method requires that all target analytes in the continuing calibration verification standard be within 30% difference from the initial calibration. According to the laboratory standard operating procedure, the continuing calibration is acceptable if it meets the laboratory control sample acceptance criteria.

Vinyl chloride recovered outside control limits for the LCS associated with analytical batch 140-32704. This is not indicative of a systematic control problem because this was random marginal exceedances. Qualified results have been reported.

Sample IA-075-A-27 (140-16367-16) was diluted due to the abundance of non-target analytes. Elevated reporting limits (RLs) are provided.

Can Certification Comments:
Due to the large number of analytes in the CCV, there is a high probability that one or more analytes will recover outside acceptance limits. The laboratory's SOP allows for several analytes to recover outside criteria for this method when analyzing for a full list. The CCV associated with the can cleaning batches had analytes outside control limits. These results have been reported and qualified

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Comments
No additional comments.

Detection Summary

Client: Tetra Tech, Inc. Job ID: 140-16367-1

FORM V
AIR - GC/MS VOA INSTRUMENT PERFORMANCE CHECK

Lab Name: Eurofins TestAmerica, Knoxville Job No.: 140-16367-1

SDG No.:

Lab File ID: RBFBH19X.D BFB Injection Date: 08/19/2019

Instrument ID: MR BFB Injection Time: 16:27

Analysis Batch No.: 32744

M/E	ION ABUNDANCE CRITERIA	% RELATIVE ABUNDANCE	
50	15.0 - 40.0 % of mass 95	28.3	
75	30.0 - 60.0 % of mass 95	58.7	
95	Base Peak, 100% relative abundance	100.0	
96	5.0 - 9.0 % of mass 95	7.3	
173	Less than 2.0 % of mass 174	0.4	(0.5) 1
174	50.0 - 120.00 % of mass 95	81.1	
175	5.0 - 9.0 % of mass 174	6.2	(7.7) 1
176	95.0 - 101.0 % of mass 174	78.5	(96.8) 1
177	5.0 - 9.0 % of mass 176	5.0	(6.4) 2

1-Value is % mass 174 2-Value is % mass 176

THIS CHECK APPLIES TO THE FOLLOWING SAMPLES, MS, MSD, BLANKS AND STANDARDS:
