Re: Transmittal of the Revised Pages to the Preliminary Investigation Report for Greater Strawberry Point Former Buildings KC, KJ, and KQ Area and Comment Responses
Martin State Airport, 701 Wilson Point Road, Middle River, Maryland

Dear Mr. Carroll:

For your use and reference, please find enclosed two hard copies with CDs of the above-referenced documents. This response to comment document and revised pages address comments received from the Maryland Department of the Environment via email on March 20, 2015.

If you have any questions or require any additional information please contact me by phone at 240-676-5392, or via e-mail at paul.calligan@lmco.com.

Sincerely,

Paul E. Calligan

Section 1
Introduction

On behalf of Lockheed Martin Corporation (Lockheed Martin), Tetra Tech, Inc. (Tetra Tech) has prepared this report presenting the results of a preliminary investigation of the former locations of buildings KC, KJ, and KQ ("the site") in the Greater Strawberry Point (GSP) area of Martin State Airport (MSA) in Baltimore County, Maryland. This area formerly housed several airport maintenance facilities, two nuclear research buildings (KC and KJ), and a liquid-metal test facility (KQ). It is referred to in previous Greater Strawberry Point and Martin State Airport reports as recognized environmental condition (REC) #11.

The investigation scope includes the following tasks: review of available regulatory records related to the licensing and oversight of historical operations at the former locations of buildings KC and KJ; a ground-surface gamma radiation survey for health and safety screening within the area of interest; and non-invasive geophysical surveys to investigate subsurface features. The information developed in this report will guide future Phase II site characterization efforts. The study objective is to obtain information regarding specific historical operations performed at the former locations of buildings KC, KJ, and KQ, and to investigate (using a subsurface geophysical survey) whether any remnants of the former buildings remain.

This report is organized as follows:

Section 2—Background: Briefly describes the site history and previous facility investigations, including Martin State Airport and Strawberry Point Facility.

Section 3—Historical Records Review: Presents the results from various records searches, including Freedom of Information Act (FOIA) requests and records from government agencies.

Section 4—Field Investigation: Provides the methodology and results of the gamma surface scan and the geophysical survey.

Section 5—Summary: Presents the overall findings of this investigation, including any conclusions made based on the records review and the geophysical survey.

Section 6—References: Cites references used to compile this report.

Appendix A contains historical maps and documents, Appendix B contains copies of Freedom of Information Act (FOIA) requests and agency responses, Appendix C contains Nuclear Regulatory Commission (NRC) Freedom of Information Act and online records, Appendix D contains Maryland Department of the Environment (MDE) records, Appendix E contains Maryland Aviation Administration (MAA) records, and Appendix F contains other relevant historical records. Appendix G consists of a photographic log, Appendix H contains gamma scan documentation, and Appendix I contains the subcontractor's geophysical investigation report.

Section 2
Background

This section presents the site description and background, including site history.

2.1 SITE BACKGROUND

2.1.1 Martin State Airport

Martin State Airport (MSA) is in eastern Baltimore County, Maryland on the peninsula between Frog Mortar Creek and Stansbury Creek; both creeks are tributaries of Middle River. Eastern Boulevard (Route 150) bounds the site to the north and the Lockheed Martin Corporation (Lockheed Martin) Middle River Complex (MRC) borders the site to the west. Figure 2-1 shows the location of Greater Strawberry Point (GSP). MSA is a regional airport, home to private and corporate aircraft, a flight training school, and the Maryland Air National Guard (MDANG). MDANG occupies the northeastern corner of the airport property.

The MSA Main Terminal facility (west of the MDANG facility and north of GSP) is at 701 Wilson Point Road, Middle River, Maryland. The current MSA property (approximately 775 acres) was part of the Glenn L. Martin Company's approximately 1,260-acre property, which included what is now the MRC complex. A search of Maryland land records and deeds indicates that the Glenn L. Martin Company purchased six parcels of land (identified as 701 Wilson Point Road) from private landowners during the spring and summer of 1929. During the 1940s and 1950s, nine additional parcels at this location were acquired from private landowners. The Glenn L. Martin Company and American-Marietta Corporation merged to become Martin Marietta Corporation in 1961. In 1969, Martin Marietta Corporation transferred the properties to Chesapeake Park, Inc., a subsidiary, which then transferred what is now the MSA property to the State of Maryland in 1975.

Aerial photographs indicate that many of the original MSA Main Terminal facilities (three runways, Hangars 1 through 6, and the administration building) were developed between 1939 and 1941. When the property was transferred to the State of Maryland in 1975, the Maryland Aviation Administration (MAA) assumed ownership and operations of MSA and the Main Terminal. The approximate 775-acre MSA property is owned by the Maryland Department of Transportation

(MDDOT). The facility is fenced, and the main entrance is at the Main Terminal facility on Wilson Point Road. Figure 2-2 shows the location of the MSA Main Terminal facility.

The 104th Tactical Fighting Group, later reorganized as the 175th Wing of the Air National Guard, occupied the MDANG facilities in 1955. The 135th Tactical Air Group was located southwest of the MDANG facility at MSA in the 1960s and 1970s, and was relocated to the current MDANG facilities in October 1980. The MDANG facility currently leases 175 acres from the MAA in the northeastern quadrant of MSA. The MDANG facility includes taxiways, parking aprons, operations and training buildings, general supply and ammunition storage facilities, fuel storage structures, maintenance shops and sheds, and aircraft hangars. See Figure 2-2 for the location of the MDANG facility.

2.1.2 Strawberry Point and Greater Strawberry Point Facility

Strawberry Point (SP) is within the confines of the MSA at the southern tip of the peninsula, between the confluence of Stansbury and Frog Mortar Creeks. SP can be accessed from Wilson Point Road via Strawberry Point Road via a secured unmanned gate. The wooded area (approximately 25 acres) at the south end of the peninsula at SP was previously investigated (Tetra Tech, 2008). The wooded area is bounded by earthen berms near the water line and thick brush and trees cover the entire area. Much of the SP wooded area was filled during the 1940s, reportedly by deposition of dredge spoils from Stansbury and Frog Mortar Creeks. A locked gate controls the entrance to the wooded area.

The remainder of the area referred to as GSP is a cleared and partially developed 75-acre site comprising a former seaplane ramp, hangars, fuel tank farm, police building, and maintenance buildings. It extends from the southern end of the peninsula to the northern end bordering Taxiway J, and eastward from Stansbury Creek to Taxiway F. The airport runway is northeast of GSP.

The United States Navy leased GSP from the Glenn L. Martin Company from December 23, 1943 until 1963. During occupancy, the Navy used a large hangar for seaplane maintenance, launching, and recovery operations. The former hangar and surrounding GSP area was known as the Naval Weapons Industrial Reserve Plant No. 148. The United States Air Force subsequently occupied the facility (Permit No.1-N-MD-714) from December 16, 1963 until 1967.

The southern portion of the GSP near the wooded portion of the site contained 10 buildings during Navy and Air Force use. These included the beach house (Building No. 3), the pumping station (Building No. 4), the chlorination station (Building No. 5), two power-fence service houses (Buildings No. 6 and 9), solvent storage (Building No. 7), the equipment storage building (Building No. 8), the power-fence switch-house (Building No. 10), the delivery hangar (Building ND/No. 11), and a general storage building (Building No. 12). A tank farm containing aboveground storage tanks (ASTs) for aircraft fuels was adjacent to the wooded area, near the southernmost tip of the developed area. Figure 2-3 is an index map of current and historical building numbers.

During the same period (1940s to 1960s), the northern portion of GSP was developed with several improvements related to naval weapons research. These structures included the induction test building (Building No. 13), the control house (Building No. 14), the noise suppression building (Building No. 15), the jet test shed (Building No. 16), the storage building (Building No. 17), the propulsion test building (Building No. 22), the compressor shed (Building No. 23), the engine test building (Building No. 24), and the vibration/slosh test building (near the location of current ground surface mounding). A missile testing area along a straight road northwest of the propulsion test building included the hyper-therm test facility (Building No. 25), the propellant storage shed (Building No. 18), the furnace building (Building No. 19), the acetylene storage shed (Building No. 20), the Vanguard tower (Building No. 21), the block house (Building No. 26), and three coupon test sheds (Buildings No. 27, No. 28, and No. 29).

Several buildings dedicated to nuclear research and testing were constructed between 1957 and 1965. These facilities were farther northwest, along a former dirt road at the northern end of the GSP wooded area. Two main research buildings were designated as the critical test building (Building No. 36/Building KC) and the radioisotope lab (Building No. 35/Building KJ). Figure 2-3 shows the location of these facilities. Historical maps and aerial photographs depicting the locations of the former buildings in the 1960s are in Appendix A.

Historical records indicate that two underground storage tanks (USTs) were installed during the time that the Navy and Air Force used facilities in the southern portion of GSP. A 10,000-gallon heating oil UST adjacent to the delivery hangar (Building ND) stored fuel for the hangar's heating system. This UST was closed in place in 1987 by the State of Maryland (subsequent to Navy and Air Force occupancy), when the hangar's heating system was converted from fuel oil to natural

gas. Both the lease and permit held by the Air Force expired on November 30, 1967. In 1961, the Glenn L. Martin Company merged with Marietta Corporation to form Martin Marietta Corporation. On June 30, 1975, MSA was conveyed to MDDOT. The State of Maryland currently uses GSP to house and maintain police and medevac helicopters. The southern portion of GSP is occupied by the Baltimore County Marine Police.

Eleven USTs have been removed from the Main Terminal and GSP since 1983, and no evidence of leakage has been reported. The large hangar designated Building ND was demolished in 1989; two adjacent hangars that currently house the Maryland State Police were constructed in 1989 and 1990. Today, GSP has a tank farm consisting of 12 ASTs for jet fuel, fuel oil, and gasoline, along with a pump house and other ancillary buildings currently used by the airport. As many as six ASTs at the tank farm are used by other tenants. Oil spills were reported in 1989 and 1990 during construction of the new hangar, when fuel oil returns and receiving lines to two 12,000-gallon ASTs in the tank farm were severed. No additional information regarding these spills has been found in Maryland Department of the Environment (MDE) records (Defense Environmental Restoration Program for Formerly Used Defense Sites [DERP-FUDS], 1991).

2.1.3 Former Radiological Research Facilities

Former Buildings KC and KJ were constructed around 1957 as research and development facilities for nuclear-reactor fuel elements. Documentation indicates that the operations at former buildings KC and KJ were carried out under multiple Atomic Energy Commission[1] (AEC) licenses and amendments. The radioisotopes used in Buildings KC and KJ were managed under AEC license specifications that included engineering controls and limitations on the types and quantities of source materials that could be stored or handled.

These buildings were at the northern end of the GSP wooded area, west-northwest of the former Vanguard area, along a curved dirt road connecting Strawberry Point Road to a former airfield-maintenance storage building (Building No. 37). Building KC, the larger of the two nuclear buildings, was on the east side of the dirt road across from the former maintenance storage building. Its location (with respect to present features) was in the grass-covered area northwest of the wooded area, partially underlying the current Taxiway J surface, about halfway between

[1]The AEC's nuclear licensing, regulatory, and oversight responsibilities were assigned to the Nuclear Regulatory Commission (NRC), which was created when the AEC was abolished by the federal Energy Reorganization Act of 1974.

Taxiway F and the corporate hangar apron. Former Building KJ was approximately 330 feet southwest of Building KC, on the eastern side of the former dirt road and across the road from the former organic material and maintenance storage sheds. This location is at the northern edge of the current stormwater-detention basin spanning the northern GSP wooded area, near a sedimentation-basin discharge-structure. The basin directs runoff from portions of MSA toward Stansbury Creek. Figure 2-4 shows the location of the former facilities and the current layout.

Building KC (the critical test facility) housed two test cells, a storage vault, and a liquid fluidized-bed reactor (LFBR; also labeled as a third test cell in building layout plans). The operations in Building KC reportedly included the bundling of uranium fuel tubes and testing under subcritical conditions (e.g., releasing energy without a sustaining nuclear chain-reaction). The license amendments for Building KC indicate that planned research operations included testing of prototype reactor cores using uranium fuel sources, including the first "MH-1A" reactors installed by the United States government on aircraft carriers to provide energy for military operations in remote locations (NRC, 1957). The completed MH-1A fuel assemblies were reportedly stored in test cells at Building KC. The presence of an underground wastewater dump/holding tank reportedly under Building KC (according to a 1994 NRC closeout report) could not be verified during the NRC's closeout inspection (NRC, 1995).

The radioisotope laboratory (Building KJ) was used to assemble and develop prototype photovoltaic generators using radioisotopes (primarily americium and curium) as an energy source (NRC, 1963), according to NRC records. The Martin Company was issued a license amendment in 1957 to process radioactive americium (Am-241) and curium (Cm-242) in Building KJ (NRC, 1995). This initial permit was an extension of license No. 19-1398, held for nuclear research and fuel processing performed in Building D (which was located nearby at what is now the Lockheed Martin MRC) before construction of the GSP nuclear facilities. An NRC closeout report indicates that no production processing was conducted in Building KJ, and that only a small source of americium was used for development operations (NRC, 1995). A February 12, 1965 application for a byproduct-material license for Building KJ was found in NRC files (NRC, 1995). This application requested the addition of promethium-147 to license 19-1398 for research activities. The promethium was to be used in powder coatings as a photon source or catalyst in experimental photovoltaic generators.

The liquid-metal test facility (Building No. 34/Building KQ) was just south of the nuclear research facilities on the eastern side of the former dirt road. Its location is near the central, northwestern boundary of the current GSP wooded area, within the existing drainage detention basin. A 1970 survey and topographic map of Chesapeake Park, Inc. shows a transformer pad (approximately 15-foot square) southeast of the liquid-metal test facility and between the building and the former edge of the wooded area. Research and records reviews to date have not documented the former usage of (and/or operations of) the liquid-metal test facility (Building KQ).

Several sheds were near the nuclear labs, including a "field service storage" shed across the road from Building KJ and an organic material storage shed across from Building KQ. A historical facility drawing dated 1963 (Appendix A) indicates that radiological research buildings and surrounding facilities at GSP were serviced by an eight-inch vitreous-clay-pipe sanitary-sewer (Martin Company, 1963). The sewer line began at Building KC and continued southwest to a pump station near Strawberry Point Road. The pump station directed sanitary sewer flow from the northern end of GSP past the Main Terminal and east to Eastern Boulevard. The radiological research facilities and surrounding storage buildings were removed by the State of Maryland sometime between 1995 and 2000 to construct Taxiway J. The current status of the sanitary sewer pipes formerly connected to the nuclear research facilities is unknown.

2.2 PHYSICAL FEATURES

2.2.1 Land Use

MSA is generally characterized as a moderately developed tract in a largely suburban, moderate density, populated setting. Land use surrounding MSA is, to a significant degree, a combination of mixed suburban, industrial, and light-to-moderate commercially developed and woodland tracts. MSA is bordered on the north by Eastern Boulevard (Maryland Route 150) and Amtrak railroad tracks. Undeveloped woodland tracts and low-density residential properties are north of MSA and the Amtrak line. The eastern, southern, and western boundaries of MSA are bordered by Frog Mortar and Stansbury Creeks. These are wide, brackish, tidal tributaries of the Chesapeake Bay. The Lockheed Martin MRC, a facility that assembles missile-launching systems and aircraft parts, is along MSA's northwestern boundary. The Tilley Chemical Company occupies a parcel at the southwest corner of the MRC, and General Electric, Inc. is the main tenant of the MRC and Chesapeake Industrial Park. Low- to medium-density residential land use and light commercial land use (e.g., shopping centers, convenience stores, restaurants, etc.) are beyond the creeks north,

east, and west of MSA. Farther east and west of MSA are the high-density residential communities of Bengies Corner and Hawthorne Park.

2.2.2 Climate

The climate at MSA is characterized as humid temperate, with hot, humid summers and relatively mild winters. The Middle River, Maryland area receives an average of 42 inches of precipitation annually, distributed evenly throughout the entire year. Rainfall occurs normally in spring, summer, and fall in the form of showers and thunderstorms. During winter, precipitation is in the form of light to heavy rain or snow. Tropical storms in late summer and fall, and occluded, meso-scale frontal systems (i.e., coastal low-pressure systems) occasionally provide short-term, above-average precipitation to the area.

2.2.3 Physiography

MSA is in the western shore of the Coastal Plain physiographic province. The Coastal Plain comprises sediments composed of alluvium from the Pleistocene Epoch and the Potomac Group from the Cretaceous Period. Coastal Plain sediments begin at the fall line and follow a regional dip to the southeast at approximately 110 feet per mile (Hansen and Edwards, 1986). The Fall Line is the division between the Piedmont and Atlantic Coastal physiographic provinces, and refers to an imaginary line connecting waterfalls or changes in stream flow between the hard-rock upland areas of the Piedmont and the soft-sediment lowland areas of the Coastal Plain. The Coastal Plain is generally characterized by low topographic relief. However, steep embankments and hills are found along stream channels, rivers, and the Chesapeake Bay.

2.2.4 Topography

Most of the land surface at MSA is generally flat to gently sloping in the areas of the airport runway, taxiways, and surrounding support operations. The airport runway forms a northwest to southeast-trending topographic ridge or drainage divide that gently slopes from the northwest to the southeast end. Runway elevations range from slightly over 20 feet above mean sea level (msl) at the northern end of the runway to slightly over 10 feet above msl at the southern end. The land also slopes northeastward and southwestward, away from the runway toward Frog Mortar Creek and Stansbury Creek.

GSP is southwest and south of the runway. Site topography ranges from flat to gently sloping to the southwest toward Stansbury Creek. In the northern portion of GSP, land elevations range from approximately 11 feet above msl near the runway to nearly mean sea level along the Stansbury Creek shoreline. A manmade drainage-channel and stormwater-detention basin are along the northwest edge of the GSP wooded area, between the current Lockheed Martin corporate hangar and the current tree line. Localized topography along Taxiway J and the paved areas adjacent to the corporate hangar is sloped toward these features, and surface water drainage follows a southerly slope toward Stansbury Creek.

2.2.5 Surface Water Hydrology

Stansbury Creek is the nearest surface water body to recognized environmental condition (REC) #11, and is approximately 800 feet south-southwest of the former nuclear research facilities. Stansbury Creek is a wide, brackish, tidal tributary of the middle Chesapeake Bay. Surface water runoff from Taxiways F and J enters Stansbury Creek via localized drainage channels and storm sewers.

A drainage channel along the northern tree line of the GSP wooded area receives surface water drainage from the wooded area (Figure 2-4). This channel directs flow southerly to a stormwater culvert that passes below Strawberry Point Road to Stansbury Creek. A stormwater-detention basin is west of the drainage channel; it spans the northern border of the GSP wooded area from Taxiway F to the truck canopy and deluge tank south of the corporate hangar.

Stormwater enters the detention basin via three storm-drain inlets that convey runoff from the developed areas west of Taxiway J. Two storm drains pass below Taxiway J and enter the basin near the location of former Buildings KC and KJ. Stormwater entering the basin from these two inlets originates primarily from the grassy area between the runway and Taxiway F and from the Main Terminal southeast to REC #11. The third stormwater inlet enters the drainage basin near the northeast corner of the existing corporate hangar. Stormwater entering the basin at this inlet originates from storm drains in the concrete apron north and east of the corporate hangar. The detention basin contains tall grass, and the soils in the basin usually remain wet.

Drainage from the northern GSP stormwater-detention basin flows southwest, where it joins flow from the stormwater culvert crossing below Strawberry Point Road. It then appears to drain to the wetlands connected to Stansbury Creek. This localized drainage system appears to have been

constructed around 2000 when the Lockheed Martin corporate hangar was built, and is separate from two stormwater outfalls (Outfalls 007 and 012) in Stansbury Creek that are managed under the MSA National Pollutant Discharge Elimination System (NPDES) permit. Although the drainage-detention basin at REC #11 is closer to Outfalls 007 and 012, the *MSA Stormwater Pollution Prevention Plan* (Maryland Environmental Service [MES], 2010) reports that it is part of the Outfall 006 drainage area.

Outfall 006 receives drainage from: vehicle/equipment maintenance and de-icing operations; chemical waste storage areas; taxiway and runway access; parking, maintenance, and auto-shop areas; a fuel farm; private tenant hangars; and storage piles of soil, asphalt millings, and stone. The approximately 85-acre drainage area includes pervious grassy surfaces along Strawberry Point Road and between parking areas and dense tree zones. It also includes impervious surfaces consisting of portions of Strawberry Point Road, taxiways, hangar and maintenance buildings, and aircraft and vehicle parking areas. Monitoring for Outfall 006 is at the exit of an existing storm-drain system discharging into Stansbury Creek.

2.2.6 Regional Geologic and Hydrogeologic Conditions

MSA is in the western shore of the Coastal Plain physiographic province. Regional and local studies (Vroblesky and Fleck, 1991; Chapelle, 1985) indicate that MSA lies on the Patapsco Formation. This formation consists of complex and interbedded mixtures of gray, brown, and red sands, silts, and clays originating from sediment deposition in a low coastal plain traversed by low-gradient meandering streams. Below the Patapsco Formation is a regionally extensive, thick-clay confining unit known as the Arundel Formation. It is a massive and probably impermeable unit underlying MSA and surrounding area.

The GSP area has been historically documented as having poor surface/soil drainage. The 1989 preliminary assessment report for Martin State Airport states that the former nuclear buildings are in the Lenoir-Urban land complex, a soil type that is somewhat poorly drained and has a slow permeability (Maryland Hazardous and Solid Waste Management Administration [MHSWMA], 1989). The former shoreline of Stansbury Creek extended more than 1500 feet north of its present location, passing along what is now the west side of the Black and Decker hangar into a wet grassy area that has never been developed. The former northern reach of the creek was partially filled in 1941; its current shoreline was filled in approximately 1945. Natural drainage patterns near the

former creek bed about 600 feet west of the former Buildings KC and KJ make the entire area vulnerable to wet soil conditions.

2.2.7 Vicinity Subsurface Conditions

Subsurface conditions at MSA have been studied since at least 1987 (MHSWMA, 1989). Detailed studies of subsurface conditions are ongoing and extensive data are available for the Dump Road Area and eastern portion of MSA. More recently, subsurface data have been collected at GSP and the western and southern portions of MSA during investigations completed from 2009 through 2012 (Section 2.3). Numerous shallow soil borings at GSP have been advanced to depths up to 40 feet to collect soil samples for subsurface lithologic information and soil and groundwater samples for chemical analyses. Subsurface conditions in the GSP REC #11 area are summarized below.

2.2.7.1 Geology

Lithology encountered in the soil borings advanced across SP and GSP varies. At RECs in the southern portion of GSP, intermittent sand and clay layers of moderate thickness predominate the relatively shallow subsurface, and are often associated with varying amounts of silt. This lithology overlays a thick northwesterly dipping layer of stiff clay that is encountered at depths ranging from approximately six feet below grade in the southeastern portion of the area to 25 feet below grade in the western portion. The clay layer may be contiguous with the shallow dipping clay in the southern portion of GSP. REC #11 lithology is comprised of sand, clay, and occasional silt layers that vary in thickness and frequency. A layer of dense intermingled sand, silt, and clay lenses below these materials is encountered at depths ranging from about 15 to 30 feet below grade.

2.2.7.2 Hydrology

Groundwater depths (measured from the top of the well casings) in REC #11 range from 3.94 feet to 10.46 feet; corresponding groundwater elevations ranged from 1.75 feet to 4.1 feet. Groundwater elevations are reported in North American Vertical Datum 1988 (NAVD88). At REC #11, groundwater flow is generally to the southeast, and is consistent with regional groundwater flow toward the southeast tip of MSA where Frog Mortar and Stansbury Creeks converge. Groundwater flow in the southwestern portion of REC #11 is locally influenced by the large drainage swale between the wooded area and Taxiway J.

2.3 SUMMARY OF PREVIOUS INVESTIGATIONS

Studies of the SP and GSP areas began in 2007 with a Phase I environmental assessment focused on the SP wooded area (Tetra Tech, 2008). The Phase I objective was to evaluate historical site activities pertaining to the wooded area, tank farm, former hangar area (Building ND), facility maintenance yard, and nuclear research buildings (Tetra Tech, 2008). The investigation reviewed historical facility documents, drawings, photographs, aerial photographs, government records (NRC, United States Environmental Protection Agency [USEPA], MDE, and Baltimore County), and related permits and violations. Interviews with former and current employees, a visual site inspection, and geophysical investigations of the wooded area were also included. During the Phase I environmental assessment, several RECs related to SP and GSP were identified, and are summarized below by area:

- REC #1—the wooded area at the southern tip of SP
- RECs #2, 3, 4, 5, and 6—known as the ramp area, covers approximately eight acres over the southern, developed portion of GSP, and includes the former hangar area (Building ND) and supporting infrastructure
- RECs #7, 8, 9, and 10—an approximately 16-acre area in the central portion of GSP, north of the ramp area and Taxiway F, east of the MSA runway, and south of the GSP northern wooded area; it also includes the current MSA maintenance facility
- REC #11—an approximately two-acre area in the northern portion of GSP that includes the former nuclear research facilities (Buildings KC and KJ)

Subsurface (intrusive) investigations of soil and groundwater conditions have been performed at the GSP RECs listed above (RECs #7 to #11). REC #1 was addressed in 2008 as a separate investigation (Tetra Tech, 2009). A subsurface investigation for RECs #2 through #11 was completed in 2010 (Tetra Tech, 2010). An additional Phase II investigation in 2011 (Tetra Tech, 2012a) and follow-on investigation in 2012 focused on the RECs #7 through #11 areas (Tetra Tech, 2013).

To date, 170 soil borings have been advanced at GSP, and chemical characterization of soil samples was performed on each boring. Nineteen soil borings were completed at REC #11 (the area containing the former nuclear research facilities) in 2010 (Tetra Tech, 2010), 20 borings were advanced in 2011 (Tetra Tech, 2012a), and 15 borings were completed in 2012 (Tetra Tech, 2013). An additional 45 membrane-interface probe (MIP) borings have been completed to characterize

subsurface conductivity at GSP, including 15 borings at the REC #11 area in 2012 (Tetra Tech, 2013). Twenty monitoring wells have been installed at REC #11; an additional three temporary well points were installed in 2010 to characterize groundwater quality.

2.3.1 2010 Phase II Site Investigation

A Phase II environmental investigation in April and May 2010 assessed subsurface conditions at GSP RECs #2 through #11 (Tetra Tech, 2010). The following field investigations were completed in REC #11:

- Soil borings were advanced to a depth of 25 feet at 19 locations in REC #11. Soil samples were collected continuously for lithologic characterization; soils were screened in the field for volatile organic compounds (VOCs) using a portable photoionization detector (PID). Select soil samples from each boring were submitted for fixed-laboratory chemical analyses of VOCs, semivolatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), metals, total petroleum hydrocarbons (TPH)-diesel-range organics (DRO), and TPH-gasoline-range organics (GRO).

- DPT-probe groundwater samples were collected at two locations in REC #11 and submitted to a fixed laboratory for chemical analyses of VOCs, SVOCs, PCBs, metals, TPH-DRO and TPH-GRO.

- Three temporary wells were installed at DPT soil boring locations, and groundwater samples were collected and submitted to a fixed laboratory for chemical analyses of VOCs, SVOCs, PCBs, metals, TPH-DRO and TPH-GRO.

The following summarizes the results of the 2010 investigation findings specific to the REC #11 study area:

- REC #11 subsurface lithology varied and ranged from an area in the north comprised of nearly all silty clay (to a depth of 25 feet) to an area in the center of REC #11 consisting of 12 feet of silty sand and sandy silt overlying 13 feet of clay. Lithology in the southern portion of the REC was comprised mostly of sandy silt and a few clay layers.

- The water table at GSP ranged from just below the ground surface to nearly eight feet below grade. Shallower groundwater levels tended to be along the eastern portion of GSP in areas where shallow clay was observed. Groundwater elevations indicate that groundwater beneath GSP generally flows in a southeasterly direction toward Stansbury Creek and Frog Mortar Creek.

- Trace- to low-concentrations of VOCs were detected in soil samples collected at all GSP RECs. However, these levels were less than Maryland residential and nonresidential soil standards. Trichloroethene (TCE), a chlorinated solvent detected at the Dump Road area of MSA, was detected at low concentrations in deep soil samples at REC #11. Some of the highest concentrations of SVOCs in GSP were detected at REC #11. However, most

detections were less than residential and nonresidential standards. SVOC concentrations slightly exceeded residential standards at several RECs, and some SVOC concentrations in REC #11 exceeded nonresidential standards. However, these exceedances were limited to surface and shallow soil at a maximum depth of seven feet below grade.

- PCB concentrations ranging from 3,100–12,000 µg/kg in three shallow-soil samples at REC #11 exceeded the Maryland residential and nonresidential soil standards of 320 and 1,400 µg/kg (respectively). A fourth shallow sample at REC #11 (1,200 µg/kg) exceeded the residential standard only.

- Concentrations of arsenic, total chromium, iron, manganese, nickel, and vanadium in soil exceeded standards in most samples. Iron and manganese concentrations varied greatly, and may be due to fill material or former buildings. Although arsenic and vanadium frequently exceeded their risk-based standards, concentrations of these two metals were generally similar to MDE's anticipated typical concentrations (ATCs) or "regional background" concentrations for the eastern region of Maryland. Therefore, concentrations of arsenic and vanadium appear to be consistent with local background and not indicative of a release at GSP.

- Concentrations of arsenic, beryllium, iron, manganese, nickel, and vanadium exceeded groundwater standards in one or more groundwater samples. Several exceedances appear to be the result of high turbidity in the samples. VOCs and SVOCs detected in groundwater samples did not exceed standards, and were typically common laboratory contaminants and artifacts of laboratory analyses.

2.3.2 2011 Additional Phase II Site Investigation

Between May and July 2011, an additional Phase II site investigation further characterized areas of soil and groundwater contamination initially identified during the 2010 GSP Phase II site investigation. The *Additional Phase II Site Investigation Report* (Tetra Tech, 2012a) summarizes the results of the test pit explorations, soil borings, soil sampling, and groundwater monitoring well installation and sampling performed within REC #8, #9, #10, and #11 at GSP. The 2011 investigation included the advancement of 40 soil borings, excavation of 12 test pits, installation of eight monitoring wells, and collection of soil and groundwater samples for chemical analyses. Human health and ecological risk assessments were also performed to quantify potential risks to human receptors and ecological impacts from detected chemicals at GSP (Tetra Tech, 2012a).

The findings pertinent to the study area in the 2011 additional Phase II site investigation and risk assessment are summarized below:

- TCE was detected at low concentrations in one or more deep soil samples in REC #11, but all were less than MDE residential and nonresidential soil standards.

- TCE concentrations in groundwater exceeded MDE and federal groundwater criteria in three REC #11 area wells (GSP-MW-01, GSP-MW-04, and GSP-SB/WP-89).

- TPH-DRO was detected in groundwater at concentrations exceeding the MDE standard in three REC #11 groundwater samples (GSP-MW-01, GSP-MW-02, and GSP-MW-03).

- TPH-DRO concentrations exceeded MDE residential soil standards in five soil samples at REC #11, and exceeded both the residential and nonresidential standards in two surface soil samples from REC #11.

- PCBs (primarily Aroclor 1260) were detected in GSP soil boring samples at concentrations ranging from 19–3,400 µg/kg. Aroclor 1260 concentrations in four shallow soil samples at REC #11 exceeded both the Maryland residential and nonresidential soil standards.

- Two of the highest SVOC concentrations in soils, and greatest occurrence of concentrations exceeding residential and nonresidential soil criteria, were identified in subsurface soil samples from REC #11 (GSP-SB-120-18–20 and GSP-SB-121-6–8).

- Detected concentrations of arsenic and vanadium exceeded MDE residential criteria and their eastern Maryland ATCs in soil sample GSP-SB-111-6–8 (southeast of REC #11). Detected concentrations of arsenic and vanadium exceeded their MDE criteria in most soil samples, but were within the range of the eastern Maryland ATCs.

- The human health risk assessment identified regulatorily unacceptable risks for hypothetical child trespassers, lifelong recreational users, and lifelong residents, from ingestion, dermal contact, and inhalation of polycyclic aromatic hydrocarbons (PAHs) (expressed as benzo[a]pyrene-equivalents [BaPEq]) in surface and subsurface soils at REC #11. Potential exposure to manganese in surface and subsurface soil by future construction workers was also associated with regulatorily unacceptable risks. TCE was retained as a chemical of concern for hypothetical future residents at REC#11, based on potential exposure to groundwater due to direct contact, ingestion, and inhalation. Based on the results of groundwater sampling and qualitative risk analysis, TCE was also considered a potential vapor-intrusion risk for a hypothetical future resident or worker.

- The human health risk estimates were calculated in a conservative manner to assist risk managers tasked with making risk management decisions for the GSP RECs. These sites are currently within the airport area and are not used for residential or recreational purposes, so the potential for trespassing is very limited. Site groundwater is not used as a domestic water supply source. Thus, largely, the risk estimates are for *hypothetical* receptor exposure, should land use change in the future.

- The streamlined ecological risk assessment identified potential risks to birds and mammals based on exposure to Aroclor 1260 in surface soil at REC #11.

2.3.3 2012 Greater Strawberry Point Supplemental Soil and Groundwater Characterization

A supplemental soil and groundwater characterization was conducted at GSP in 2012 at RECs #7 through #11 to further determine the nature and extent of environmental contamination in soil and

groundwater. Specific chemical constituents and their concentrations in soil and groundwater were identified using field-screening techniques and fixed-laboratory analyses. Chemical analytical results were screened against Maryland human health standards for soil and groundwater to assess the need for additional sampling or to support no further action.

The following field investigations were completed in REC #11 during the 2012 investigation:

- Soil and groundwater were screened using MIP to a maximum depth of 44.6 feet below grade at 15 locations in REC #11 to help locate and delineate possible areas of subsurface contamination.

- Soil borings were advanced at 15 locations in REC #11 to 40 feet below grade via DPT to collect soil lithologic information, to screen soil in the field for VOCs using a PID, and to collect soil samples for fixed-laboratory chemical analyses of VOCs, SVOCs, PCBs, metals, TPH-DRO, TPH-GRO, and toxicity characteristic leaching procedure (TCLP) analytes.

- Four new groundwater monitoring wells were installed in REC #11 and two soil samples from each well boring were submitted to a fixed laboratory for chemical analyses of VOCs, SVOCs, PCBs, metals, TPH-DRO, and TPH-GRO.

- Groundwater samples were collected in April 2012 from existing monitoring wells and submitted to a fixed laboratory for the same chemical analyses listed above.

- Groundwater samples were collected in October 2012 from the newly installed monitoring wells and submitted to a fixed laboratory for previously listed chemical analyses.

- Static groundwater levels were initially measured at the newly installed monitoring wells and at existing monitoring wells on October 4, 2012. The static groundwater levels were measured again on October 23–26, 2012, and these levels were used to develop groundwater-elevation contour maps.

- Horizontal and vertical coordinates were surveyed for the MIP borings, DPT-advanced soil borings, and monitoring wells.

The following summarizes the results of these activities:

- The water table at GSP ranged from 4.45 feet to 13.3 feet below grade (measured from the top of the well casings). Groundwater elevations range from -6.69 feet NAVD88 at GSP-MW18 (REC #11) to 8.18 feet NAVD88 at GSP-MW-14 (REC #7).

- Groundwater elevations indicate that groundwater beneath the GSP generally flows in a southerly direction toward Stansbury Creek and Frog Mortar Creek.

- MIP screening indicated possible VOCs in soil in REC #11. Several elevated responses were recorded, especially from the electron-capture detector (ECD) in the southwestern portion of the REC.

- Trace to low concentrations of VOCs (including TCE) were detected in soil samples collected at all RECs. However, no sample in REC #11 exceeded the Maryland residential soil standard.

- SVOCs were detected in soil at several RECs, but most SVOC concentrations were less than the residential and nonresidential standards. BaPEq and associated compounds were the only SVOCs detected at concentrations exceeding their screening criteria. In REC #11, 13 soil samples contained BaPEq at concentrations exceeding the residential screening criterion, with five also exceeding the nonresidential screening criterion.

- No soil concentrations of PCB, TPH-DRO, or TPH-GRO exceeded MDE cleanup standards in samples collected during the 2012 investigation.

- Concentrations of arsenic, chromium, and vanadium in soil exceeded standards in some samples from all investigated RECs. Although arsenic and vanadium frequently exceeded their risk-based standards, detected concentrations of these two metals were generally similar to MDE ATCs for the eastern region of Maryland. Thallium was detected at a concentration exceeding its residential screening criterion in one sample from REC #11, although at a concentration below its ATC. Therefore, concentrations of these metals appear to be consistent with local background and not indicative of a release at the GSP.

- Low concentrations of the metals arsenic, barium, and chromium were detected in one of two samples collected from REC #11 and submitted for TCLP analysis, while a low concentration of the SVOC 3&4-methylphenol was detected in the other sample. TCLP results do not indicate constituent concentrations at hazardous levels.

- TCE was detected in groundwater at concentrations exceeding its MDE criterion in two REC #11 wells (GSP-MW-4 and GSP-MW-18). Two additional VOCs (1,2-dichloroethane and vinyl chloride) exceeded their respective MDE criteria in REC #11 groundwater samples collected from GSP-MW-18.

- The SVOC naphthalene was detected in groundwater at one REC #11 well (GSP-MW-18) at a concentration exceeding its MDE criterion.

- At REC #11, TPH-DRO concentrations exceeded MDE criteria in four of eight wells: GSP-MW-1 and GSP-MW-20 in the eastern portion of REC #11, and GSP-MW-4 and GSP-MW-18 in the southwest portion of REC #11

2.4 CURRENT SITE CONDITIONS AND OPERATIONS

The investigation area for Buildings KC, KJ, and KQ includes an approximate two-acre partially wooded area at the northern end of GSP. Currently, REC #11 contains no structures east of the Lockheed Martin hangar except for the stormwater detention basin and associated stormwater drainage systems and has no planned improvements. Former Buildings KC, KJ, and KQ were

demolished in 2000 so that Taxiway J and the corporate hangars could be constructed. The stormwater detention basin was constructed when Taxiway J and related midfield improvements were constructed. The detention basin supports tall wetlands vegetation (most greater than four feet high). South of the detention basin is a stream channel that intermittently drains REC #11 and overflow from the detention basin. A large earthen berm, nearly 20 feet wide and five feet tall, is between the drainage basin and stream channel.

The REC #11 area is bounded to the north by Taxiway J, to the east by Taxiway F, to the west by Strawberry Point Road, and to the south by a wooded area extending south to REC #10 and the former Vanguard area. A flat grassy area lies north of REC #11 beyond Taxiway J and between the leased hangars and Taxiway F. The Lockheed Martin corporate hangar is northwest of REC #11 at the western end of Taxiway J. The Black and Decker hangar is immediately northwest of the Lockheed Martin hangar. A grassy median and the main MSA runway are east of REC #11 beyond Taxiway F. Aircraft traffic occurs daily on Taxiway F and planes regularly taxi to and from the corporate hangar area across Taxiway J. Figure 2-4 shows the current features in and around Buildings KC, KJ, and KQ.

Section 3
Historical Records Review

The following section summarizes agency information requests and the historical records review. This records research supplements previous records reviews conducted during a previous site investigation (Tetra Tech, Inc. [Tetra Tech], 2008), as described in Section 2.3.

3.1 FEDERAL AND STATE RECORD SEARCHES

Tetra Tech sent written Freedom of Information Act (FOIA; Public Information Act 5 U.S.C. 552) requests to the Nuclear Regulatory Commission (NRC), the Maryland Department of the Environment (MDE), and the Maryland Aviation Administration (MAA) for available records pertaining to past operations at the former nuclear research facilities in Greater Strawberry Point (GSP) Buildings KC, KJ, and KQ. The FOIA request letters and responses are in Appendix B. Records retrieved and reviewed in response to FOIA requests are summarized below. Copies of the federal and state records reviewed are in Appendices C, D, and E. In addition to requests submitted for agency-owned records, publicly available NRC records were researched and reviewed using the NRC online document repository—*Agencywide Documents Access and Management System* (ADAMS). Microfiche and electronically available records at the NRC's public library in Rockville, Maryland were also searched in person using the library system of records. Copies of ADAMS and NRC library records are in Appendix C.

3.2 NUCLEAR RESEARCH PROGRAM RECORDS OVERVIEW

The files obtained from NRC and MDE for this investigation are more extensive than those records obtained during the historical review completed for previous investigations (Section 2.3). These records provide information regarding the research performed at the site and the types and quantities of nuclear materials used. However, operational, procedural, and contractual documentation related to the programs is absent or partial; many records were presumably withheld for security reasons, given that the origins of these programs were associated with national defense. Some records obtained via this FOIA request were duplicates of those obtained during a prior site investigation (Tetra Tech, 2008).

Nuclear research was conducted in the 1950s and 1960s both at the Middle River Complex (MRC) in former Buildings C and D, as well as in former Buildings KC and KJ in Greater Strawberry Point (GSP). Original records (i.e., Atomic Energy Commission [AEC] licenses) were often universal to the Baltimore operations, without referencing a particular building or research area. In many records, specificity to a location or building can be inferred based on a reference to a program or experimental focus. For example, if the "critical facility" was referenced, the research primarily occurred in Building KC. An overview of the former Martin Company nuclear activities in the 1950s and 1960s (when research was first housed in the former Building D and then expanded to Martin State Airport) is provided below.

The Martin Company's Nuclear Division was formed in 1954. The division was centered in Baltimore but provided oversight for other nuclear research operations, including those at the radioisotopes pilot plant in Quehanna, Pennsylvania. At the MRC facilities, the Auxiliary Power Systems Department produced a variety of direct-conversion generators, including the Systems Nuclear Auxiliary Power (SNAP) generator, designed with no moving parts. It was the first to use the decay heat of radioisotopes as a basic energy source, and was developed at the MRC and Martin State Airport (MSA) facilities in the late 1950s using sealed radioisotope sources procured from Mound Laboratories in Miamisburg, Ohio (P&HS, Inc., 1987). Similar generators, used in the first nuclear-powered satellite (the Transit) and in the world's first radioisotope fueled weather station, are still used today.

Operations at former Building KC included research and development for a liquid fluidized-bed reactor (LFBR). "Packaged power plants" were also developed there, under contract with the AEC and the United States Navy. The packaged power plants were portable and used for power generation in remote military or research locations, such as McMurdo Sound, Antarctica. Some examples were the MH-1, MH-1A, PM-1, and the PM-3A. Research in the former Building KJ (radioisotope laboratory) is not well documented in the available records. The license for processing americium and curium and preparation of sealed sources (19-01398-20) in Building KJ was issued to the Martin Company in 1960. Records describing the purpose and usage of Building KQ were not located in the standard record sources described below. However, limited information regarding Building KQ was found in United States Department of Energy archived reference sources, as described in Section 3.7.

3.3 PAST RESEARCH SUMMARY

Regulatory agency records related to nuclear activities at the former facilities were reviewed during previous GSP investigations, including the 2008 Phase I environmental assessment (Tetra Tech, 2008). Many records previously reviewed were identified in this current search, due to overlapping licenses or synonymous search terms. Duplicate records were re-reviewed for information specific to Buildings KC, KJ, or KQ. This section summarizes information specific to Buildings KC and KJ that was reviewed again for this report, as documented in previously obtained NRC records (Tetra Tech, 2008). Information regarding Building KQ was not found in records obtained during previous environmental investigations.

Radiological research at Buildings KC and KJ was reportedly discontinued around 1964 and 1969, respectively. In 1965, Ebasco was licensed to dismantle and remove the LFBR from Building KC. No records of post-removal operations have been found on file, although documentation that the LFBR never achieved criticality is available (NRC, 1995). Reportedly, decontamination of the LFBR-wastewater holding tank was completed by sandblasting the tank and the residue was disposed of at a licensed burial site (NRC, 1995). According to the NRC closeout report, multiple licenses at MRC and MSA and license No. 19-01398-20 for Building KJ were terminated in late 1969 (NRC, 1995). The final cleanup and survey of Building KJ was reportedly performed by Isotopes, Inc., and included removal and disposal of the high-efficiency particle absorption (HEPA) filters used in the building. The wastewater holding tank at Building KC was reportedly abandoned in place. No records were identified that document the tank abandonment, or whether environmental testing was completed in or around the tank.

Closeout Verification Inspection Summary No. 94-001: Representatives of NRC and MDE conducted the closeout inspection of MRC and MSA facilities on November 3, 1994. The inspection and survey included MRC nuclear research laboratories (Building D and Building C), and GSP Buildings KC (critical test facility) and KJ (radioisotope laboratory). The facilities were reviewed against their issued licenses to determine if the licenses could be terminated, allowing the buildings to be released for unrestricted use. The inspectors also contacted and interviewed current and former employees of Lockheed Martin. The report concluded that no radiation above background levels was identified, and that no further action was required to release the sites for unrestricted use.

Radioisotope Laboratory (Building KJ): License No. 19-01398-20 was issued to Martin Marietta to conduct research using americium-241 (Am-241) and curium-242 (Cm-242) in Building KJ (the radioisotope laboratory). This type of work had been previously performed in Building D. The license was transferred to Isotopes, Inc. without a change in license number or work location. In late 1969, Isotopes, Inc. requested termination of the license, stating simply that all radioactive material possessed under the license had been disposed of in accordance with 10 CFR 20 by transfer to a company authorized to receive the licensed material. The AEC terminated the license without comment. No record of a termination or confirmatory survey is in the docket file. Mr. Richard Brisson (a former Martin Marietta and Isotopes, Inc. employee) stated that production processing did not occur in Building KJ, and that only small sources (microcurie amounts of Am-241, no Cm-242) were used in the building. He and one other member of the Isotopes, Inc. staff performed the final cleanup and survey of the facility, including the removal and disposal of the HEPA filters. Mr. Brisson's recollection is that this survey (demonstrating that the facility was ready for unconditional release) was sent to the AEC contracting office on Hudson St., New York City, New York (NRC, 1995).

Critical Test Facility (Building KC): Building KC, the critical test facility, was 330- feet northeast of Building KJ. The Martin Marietta LFBR was in one of the building's three "test cells." Completed MH-1A fuel assemblies were stored in the test cells under license No. SNM-53. License No. SNM-907 was issued to Ebasco Services, Inc. in 1965 to dismantle and remove the LFBR. The license included a provision to provide records for a post-removal survey to the AEC's New York Operations Office and to Martin Marietta. Although a pre-dismantling survey was performed, no records of the required post-removal survey could be found in the docket file. However, the LFBR never achieved criticality, according to documents in the file. Mr. Thomas Flynn (formerly an engineer with Raytheon-Ebasco Services, Inc.) stated that meticulous care was taken during dismantling to prevent the spread of any contamination. He further stated that an AEC inspector/health physicist from the New York field office/laboratory was on site, had overseen the final survey, and had signed the final report asserting that the dismantled LFBR had not added contamination (as compared to levels measured before operation) (NRC, 1995). Mr. Brisson confirmed that Ebasco's work produced no contamination, and stated that his group decontaminated the underground water-dump/holding tank by sandblasting the insides and disposing of the residue at a licensed burial site.

January 25, 1995 letter from NRC to Ms. Joanne Brooks, Maryland Aviation Administration: This letter was issued by NRC to confirm that the 1994 inspection identified no radiation above background levels at any of the sites. Based on these findings, no further action was recommended, and the sites were considered suitable for unrestricted use.

3.4 NUCLEAR REGULATORY COMMISSION RECORDS

Although many NRC records obtained during this investigation do not reference a specific facility, some records identify the critical facility (Building KC) or radioisotope laboratory (Building KJ), and include information for locations and types of radioactive materials used at the facilities during operation. Records obtained from NRC include ADAMs online records and public archives at the NRC library in Bethesda, Maryland. A summary of the information in the regulatory files relevant to the Greater Strawberry Point area radiological facilities is provided below.

3.4.1 Nuclear Regulatory Commission Agency-Wide Documents and Management System Research

A search of the NRC online document collection ADAMS generated multiple records that included duplicates of many previously obtained files (Tetra Tech, 2008). ADAMS records specific to Buildings KC and KJ (none for Building KQ) were obtained; relevant records are in Appendix C. Most of the records retrieved are associated with Building D activities. A brief synopsis of the records related to Buildings KC and KJ follows:

- ADAMS accession #ML080170107—This report documents the NRC closeout verification inspection (94-001) performed on 11/3/94. NRC personnel surveyed Buildings C and D at the Middle River Facility and Buildings KJ (radioisotope laboratory) and KC (critical test facility) at the Martin State Airport. The report states that an attempt was made to locate the underground dump/holdup tank described by a former employee. The inspectors were unable to locate the tank or any indication that it had been removed. We believe that the tank was probably abandoned in place. The report concluded that the facilities were suitable for unrestricted use.

- ADAMS accession #ML073400683, #ML080170088, #ML0734400526, #ML073400522, and #ML073400518—Oak Ridge National Laboratory site summaries of AEC license #19-01398-32, #STB-00187, #SNM-00053, and #SNA-00011. These reports summarize the operations and licensed quantities of radioactive material used in Building D. However, since some of the licensed activities were also performed in Buildings KC and KJ, mention is made of an NRC closeout inspection performed on 11/3/94 which addressed the operations in all three buildings.

- ADAMS accession #ML080150518—"Proposed Amendment to Byproduct Material" (license #19-01398-20). The license application discusses proposed research to be

performed in Building KJ, including experimental research on irradiated coupons of proposed reactor coolant and zircalloy (a proposed containment material). Research involved various analyses performed in ventilated hoods.

- ADAMS accession #ML080160081, #ML080160093 and #ML080160324—Correspondence between Isotopes Nuclear Systems Division, Martin Marietta Corporation, and the NRC. These documents discuss the completed decontamination of Building KJ and requests release of the building for public use. It also documents an AEC closeout inspection performed on 6/27/69, and subsequent approval of the building for unrestricted use.

- ADAMS accession #ML00070079—"Application for General License to Receive, Possess, Use, and Transfer Special Nuclear Material" is for proposed activities that were performed in Buildings D and KC, which included operation of the pilot manufacturing plant. This plant, in the basement of Building D, produced stainless-steel tubular fuel-elements containing highly enriched uranium oxide. Zero power testing of the prototype reactor cores was to occur in Building KC, according to the application.

3.4.2 Nuclear Regulatory Commission Records Produced Pursuant to Freedom of Information Act Request

Previous NRC record requests identified a large body of records possibly applicable to GSP and/or the MRC. Many of these records were publicly available online or through other public sources (e.g., ADAMS, the NRC library, etc.). Therefore, the FOIA request submitted to NRC was narrowed to documentation retrieved by NRC and not otherwise publicly available. Copies of the FOIA requests and agency responses are in Appendix B. Appendix C contains the NRC records, and any new information not obtained from prior reviews or summarized in previous reports is presented below.

Building KC operations were initially licensed in 1960 under transfer of "Special Nuclear Material" (SNM) license SNM-53 to develop and fabricate uranium/aluminum-alloy fuel elements. A 1960 letter from the Martin Company to AEC (NRC record A/45, docket No. 07000058) documents the fuel cores reportedly handled in Building KC. These operations involved fuel cell research and development using aluminum-uranium cores assembled in former Building D.

A December 12, 1957 letter from the Martin Company to the AEC (NRC record B/1, ML080320099) consists of the application for license SNM-53. An amendment to Martin Nuclear Division (MND) technical document No. 1063, "Criticality Precautions Manual," was included as an attachment to the license application. A map showing the work areas in Building KC was

included (Plate 3) with MND-1063. The map shows two test cells ("A" and "B"), a storage vault with a licensed capacity of 100 kilograms of uranium-235, and an assembly room.

A March 18, 1960 letter from the Martin Company to the AEC (record A/48, docket No. 07000058) indicates that the test cells in Building KC were being used to store PM-1 and Army Nuclear Power Program (ANPP) reactors. Subsequent correspondence on March 23, 1960 (record A/49, docket No. 07000058) refers to a storage vault in Building KC, 22 feet by 13 feet by 11 feet high, with walls of reinforced concrete nine inches thick. Birdcages (storage containers for source materials) were placed on racks along the walls at least 17 inches above the floor to avoid potential flooding. Storage racks for fuel elements were in the center of the room.

3.5 MARYLAND DEPARTMENT OF THE ENVIRONMENT RECORDS

On January 16, 2014, Tetra Tech submitted a Public Information Act (PIA) request for MDE files (Appendix B). Appendix D contains the MDE records produced by this request. Some files had been previously obtained; these records are summarized in Section 3.2. Tetra Tech reviewed a previously obtained State of Maryland report (report MD-304, "A Preliminary Assessment [PA] of Martin State Airport, Middle River, Maryland") dated March 1989 prepared by the Maryland Hazardous and Solid Waste Management Administration (MDE/MHSWMA). This PA references two memoranda prepared by MDE/MHSWMA:

- a memo dated March 30, 1989 to the Hazardous Waste Enforcement Division concerning stored materials in the abandoned Martin State Airport former nuclear research buildings
- a memo dated March 31, 1989 to the MDE Toxic Environmental Science and Health Center for Radiological Health concerning the lack of records for past generation and disposal of hazardous/radioactive waste from these facilities

These memoranda and any related correspondence were specifically requested from MDE on January 16, 2014. However, this information was not available. No new information regarding Buildings KC, KJ, or KQ was obtained via the PIA request to MDE. Note that the Closeout Verification Inspection Summary (No. 94-001), as summarized in Section 3.3, included photographs taken in 1994 of the interior of Buildings KC and KJ (Tetra Tech, 2008). The buildings were in deteriorated condition at that time (particularly Building KJ) and were overcrowded with abandoned maintenance supplies such as lime. The 1994 inspection summary did not reference the above-referenced MDE/MHSWMA memoranda.

3.6 MARYLAND AVIATION ADMINISTRATION RECORDS

On January 23, 2014, Tetra Tech contacted MAA to request records concerning the demolition of former Buildings KC, KJ, and KQ. The records MAA provided are in Appendix E. Demolition of these three buildings was carried out around 2000 by the State of Maryland as part of the "midfield" improvements at MSA. MAA provided a set of engineering drawings by TAMS Consultants, Inc. dated September 1998 entitled "Midfield Terminal Complex Site Development Phase I" (Appendix E).

The drawings note that Buildings KC, KJ, and KQ would be demolished following "removal of asbestos and other hazardous materials," and include partial floor plans for all three buildings (Sheet X-01). The Building KC floor plan includes a storage vault labeled as a "safe" and three test cells. The Building KQ floor plan identifies two tanks inside the building to be removed, but the tank volume and contents are not specified. All three buildings contained asbestos materials (e.g., floor tiles and pipe insulation). The plans present existing conditions for buildings and utilities from a construction and demolition perspective, but provide no information about environmental conditions, potential hazards associated with building components, and building-related utilities in the subsurface.

Of significance in the 1998 MAA engineering records is a topographic land survey completed by A. Morton Thomas & Associates, Inc. for the northern GSP (midfield development) in December 1996. The survey was conducted when Buildings KC, KJ, and KQ still stood. Some corners of the buildings were in the survey and provided "as-built" locations for the buildings relative to other MSA features, such as the runway. Previous maps showing these buildings approximated locations based on 1950s hand-drawn facility plans. The 1996 survey data was used to update current MSA map layers for use in GSP investigations and reports. Because the locations of Buildings KC, KJ, and KQ were adjusted, the former locations of several other buildings nearby were also adjusted. The revised maps are more accurate, and have been incorporated throughout this report.

Addendum No. 1 to the scope of work for Midfield Terminal Complex Site Development Phase I under state contract MAA-CO-97-019 dated April 27, 1998 includes questions and answers from a pre-bid site meeting. One bidder asked whether waste concrete would be allowed to be used as backfill in embankments (i.e., at the REC #11 drainage swale); the response indicates that waste concrete would not be allowed as backfill, and an addendum to the scope of work would provide

clarification. Another questioned Sheet D-01 because it does not clearly specify the types of hazardous materials removed during demolition. The response states that asbestos and traces of lead paint were the only hazardous materials anticipated to be encountered in the buildings.

Addendum No. 3 to the 1998 scope of work suggests that removal of up to 400 linear feet of underdrain pipe near Buildings KC, KJ, and KQ was a contract item. Removal of a sewer pump-station at the southern end of the dirt road was also specified in the scope of work. Therefore, the referenced underdrain may have been the former vitreous clay pipe that served as a sanitary sewer line.

3.7 OTHER HISTORICAL RECORDS

Although the FOIA requests and standard record sources examined for this investigation reveal no information regarding former Building KQ operations, a published journal article was found alluding to the liquid-metal test facility (C&E N, 1962; see Appendix F). The article indicates that in early 1962, the nuclear division of the Martin Company was finishing construction of a new research facility near Baltimore, Maryland. We assume this article and the photographs mentioned below pertain to Building KQ. The facility reportedly studied coolant systems used for the liquid-metal components of nuclear reactors used in space propulsion. Heated metals were pumped through loop systems to gather data on heat exchange.

The only test metal mentioned in the article was lithium; however, the article suggests that it was the first of many metals to be tested. Lithium was desirable for use in space systems due to its light weight. The article also mentions that cesium vapor, nickel-cadmium, and chromium were used in the test-loop apparatus (e.g., in coils and as insulators). Photographs of the liquid-metal test loop are also included in the article. No other information regarding the history of Building KQ was identified in available record sources.

A facilities map titled “Piping Distribution Mains” (dated 6/10/1963) is in Appendix F (see also Appendix A). This map shows the locations of Buildings KC, KJ, and KQ and the layout of water, gas, and sewer lines in GSP. A six- to eight-inch cast-iron pipe carried water to most of the maintenance/storage and nuclear research buildings in the area via a 12-inch county-supplied water main along Strawberry Point Road. Sanitary sewer from the GSP area was conveyed via an eight-inch vitreous-clay pipe to a pumping station formerly near the intersection of Strawberry Point Road and the former dirt road in recognized environmental condition (REC) #11. From there,

flow was directed west on Strawberry Point Road to a second pump station, where it was transferred to a 12-inch force-main sanitary-sewer line along Wilson Point Road. As described in Section 3.6, the demolition of the former pump station, and presumably the associated vitreous-clay-pipe sanitary-sewer line, were included in the demolition contract for Buildings KC, KJ, and KQ. Details regarding the condition or disposal of these materials were not identified in available records.

Section 4
Field Investigation

Field activities conducted on April 16, 2014 in the northern portion of Greater Strawberry Point included a gamma survey and geophysical survey. Photographs from the field investigation are in Appendix G. Gamma scan documentation is in Appendix H, and the contractor's geophysical survey report is in Appendix I.

4.1 GAMMA SURVEY

A gamma scan was performed at the ground surface over the entire investigation area before field activities began to screen for possible radiological hazards. This survey was performed as a health and safety measure for personnel working in the area. A Ludlum Model 2221 scaler/ratemeter combined with a Ludlum Model 44-10 gamma-scintillator probe was used for the survey. The 44-10 probe is a sodium iodide (NaI) gamma scintillator primarily used to detect high-energy gamma radiation ranging between 60 kiloelectron volts (keV) to 2 megaelectron volts (MeV); thus, it can detect gamma-emitting isotopes such as uranium-235 and cesium-134. The probe consists of a two-inch-diameter, two-inch-thick NaI crystal coupled to a photomultiplier tube housed in an aluminum canister. The scintillator/photomultiplier sends a constant stream of data to the Ludlum 2221 instrument. The electronics in the Ludlum 2221 instrument then display and output the gross count rate in counts per minute (cpm) at a rate of 1 hertz (Hz).

For this survey, the Ludlum 44-10 probe was carried 18 inches above the ground surface along survey lines spaced at five feet. Background measurements were collected in a nearby off-site area with similar surfaces (e.g., grass, concrete, and asphalt). The sensor was also tested with a cesium-137 (^{137}Cs) spike-source to ensure proper responses. Signal fall-off tests were also performed using a ^{137}Cs spike-source placed in the ground surface. Survey results in the areas of concern were similar to background and can be found in Appendix H, along with instrumentation information.

4.2 GEOPHYSICAL SURVEY

Tetra Tech performed the site geophysical surveys to locate subsurface anomalies possibly associated with buried materials. Enviroscan, Inc. (Enviroscan) conducted a reconnaissance-level electromagnetic survey over a four-acre area using a Geonics EM-61 Mark 2 metal detector and followed up with ground-penetrating radar (GPR). The primary purpose of the survey was to detect and delineate possible former building remnants, subsurface waste, or demolition debris within the investigation area. The follow-up surficial GPR survey further characterized areas of interest for possible distinct anomalies. Figure 4-1 shows the geophysical survey area. The Enviroscan geophysical investigation report is in Appendix I.

Surface conditions in the survey area consisted of the paved taxiways, grassy areas along the taxiways, the dirt access road between Taxiway F and Greater Strawberry Point (GSP), and the margins of the wooded area in the northern portion of GSP (where brush was sufficiently sparse to allow instrument navigation). Instrument navigation was not possible over the entire study area due to the uneven terrain, standing water, and dense wetland vegetation. A paved area east of the Lockheed Martin corporate hangar was also surveyed using a TW-6 pipe-and-cable locator and the GPR. Attempts were made to survey this area because the footprint of a former government-furnished equipment-storage shed appears to overlap the area. However, upon interpretation, these data were deemed not meaningful due to the presence of utilities and the perimeter fence.

4.2.1 Electromagnetic Survey Methodology

Electromagnetic (EM) mapping of the area using a Geonics EM-61 Mark 2 metal detector was performed to evaluate the presence/absence of subsurface metallic materials. The instrument uses a one-meter by one-half meter coil to transmit 150 EM pulses per second into the ground at each measurement station. A second transmitter coil is used to narrowly focus the pulses and to minimize possible interference caused by overhead and/or nearby magnetic sources (e.g., buildings, fences, power lines, surficial debris, and atmospheric EM activity).

The instrument receiver-coil measures the decay of transient electrical currents induced by the transmitted pulses. Electrical currents in moderately conductive earth materials (e.g., damp clays, mineralized or oxidized soils, etc.) dissipate rapidly, so more prolonged currents are likely due to buried metallic objects. The EM-61 Mark 2 detects and measures the prolonged transient currents

between transmitted pulses, thus providing a real-time digital read-out of the metallic content in the subsurface.

The survey scanned the investigation areas by automatically collecting EM readings at a frequency of eight readings per second along parallel profiles spaced approximately five feet apart and spanning all accessible portions of the survey area (Figure 4-1). Location control (with sub-meter accuracy) was provided by a differential global positioning system (GPS) to ensure environmental geographic information system (EGIS)-compatible mapping. Measurement locations were recorded using a mobile GPS receiver, with differential corrections applied relative to a fixed base-station GPS receiver. EM-61 and location data were analyzed on-site to identify targets for follow-on GPR scans. The larger targets identified with EM-61 were marked with plastic pin flags and/or marking paint. Many small scattered metallic items were observed with EM-61 or were visible on the surface throughout the survey area. The size and magnetic strength (density) of these metal debris items was investigated with the TW-6 pipe-and-cable locator to assess their suitability for follow-on investigation, and many of the smaller EM-61 anomalies were also marked for follow-on GPR scans.

4.2.2 Ground-Penetrating Radar Methodology

The GSSI SIR-2000 GPR instrument was used to obtain focused data in areas where the EM-61 subsurface scan indicated possible buried metallic objects. The GSSI SIR-2000 was operated with a dual frequency 800/300-megahertz antenna. First, areas of anomalous EM-61 data were re-acquired using a TW-6 pipe-and-cable locator. The TW-6 was used to locate/confirm the target anomaly, refine the target anomaly boundaries, and set the limits for GPR scans. GPR data were then collected at each follow-on location, over several parallel lines and along two perpendicular axes, to help identify the shape and orientation of the anomalies. GPR systems produce cross-sectional images of subsurface features and layers by continuously emitting pulses of radar frequency energy from a scanning antenna as it is towed along a survey profile. Radar pulses are reflected at interfaces between subsurface materials that have differing dielectric properties and return to the antenna. The GPR images are continuously displayed on a color monitor as a cross-section in real time. Areas or items exhibiting radar results of interest were marked with plastic pin flags and/or marking paint. In some cases, prior markings designating EM-61 results were adjusted based on GPR results.

4.3 GEOPHYSICAL SURVEY RESULTS

Geophysical anomalous areas of interest were identified by the EM and GPR surveys (see Figure 4-1). No anomalies were identified below Taxiway J or the concrete aprons near the hangars. Based upon the survey data, the blue rectangles/ovals shown on Figure 4-1 are representative of scattered metallic debris characteristic of urban fill. The purple rectangles/ovals shown on Figure 4-1 indicate items of interest (e.g., tanks, drums, or building remnants) based on their characteristic shape(s) in the survey data. Detailed results are provided in the geophysical investigation report in Appendix I.

Once all anomalies had been identified by EM-61, the GPR was used to ascertain physical characteristics through vertical radar imaging. Numerous small anomalies (smaller than a paint can) were scanned with GPR, but were not considered significant targets for environmental investigation because of their size. Eighteen larger anomalies were considered environmentally significant because their EM-61 images or locations indicated possible former building structures, underground storage tanks (USTs), or drums.

The GPR results for 14 of the 18 larger anomalies did not indicate of building foundations, USTs, or drums. Rather, they had the appearance of scattered (metallic) demolition debris or other metallic debris in fill. One large area of debris, shown as the largest blue rectangle on Figure 4-1, is near the former locations of two maintenance storage sheds (KH-1 and KH-2). Another area of debris, designated as a rectangle on Figure 4-1, is near the former liquid-metal test facility (Building KQ). As shown on Figure 4-1, many other former structures coincide with aircraft aprons or hangar areas that were constructed around the year 2000, but the EM-61 results do not indicate remnants of former buildings below the scanned concrete areas.

The GPR survey delineated four anomalies of interest near the former GSP REC #11 maintenance storage and nuclear research buildings that suggest structures, drums, or cylindrical objects. These four anomalies are labeled on Figure 4-1, and are described below:

- ***Anomaly of Interest 1***—a linear, upright (oriented along a plane perpendicular to the ground surface) anomaly that could indicate a possible foundation or wall remnant. This anomaly is near a former maintenance storage building (KI).
- ***Anomaly of Interest 2***—a long, high-amplitude, parabolic anomaly in the soil berm between the stormwater-detention basin and the drainage channel at the northern border of the wooded area that resembles a broken segment of large-diameter buried drain pipe,

possibly displaced or abandoned during construction of an adjacent storm drain from Taxiway J.

- ***Anomaly of Interest 3***—a parabolic response suggesting two rounded or semi-cylindrical objects each approximately 1.5- feet-wide, across their short axes. GPR images suggest an approximately two-foot separation between the objects, which may have flat or boxed edges in one direction. The area containing the similar-shaped objects within Anomaly of Interest 3 is about six feet by six feet, and the total area of the anomaly is approximately 30 feet by 35 feet. This anomaly is also within the soil berm separating the stormwater detention basin and the drainage channel. The location of Anomaly of Interest 3 appears to be near the eastern corner of former Building KQ (see Figure 4-1).

- ***Anomaly of Interest 4***—a cluster of several objects consistent with buried construction/demolition debris in the soil berm separating the stormwater-detention basin and the drainage channel, near the southernmost corner of former Building KQ.

Visual reconnaissance of the berm between the stormwater-detention basin and the wooded area identified exposed construction and demolition debris, such as bricks, metal strips, and concrete exposed and protruding from the soils along the sides of the berm (see Appendix G).

Section 5
Summary

The former sites of Buildings KC, KJ, and KQ and associated areas were investigated to evaluate historical site activities and the possible presence of subsurface remnants of the buildings and utilities. This investigation reviewed available facility drawings and aerial photographs, and agency records (Nuclear Regulatory Commission [NRC], Maryland Department of the Environment [MDE], and Maryland Aviation Administration [MAA]) for information regarding past operations and facility closure and/or demolition. A surface-gamma screening for health and safety of field investigation personnel and a geophysical investigation of the area were also conducted. A summary of the investigation findings is provided below:

- Requests for available historical license, facility operations, and demolition records were submitted through the Freedom of Information Act (FOIA) and Public Information Act (PIA) to the Nuclear Regulatory Commission and the Maryland Department of the Environment. The Freedom of Information Act and Public Information Act record search yielded records that had already been reviewed for previous investigations. Information from the records search is summarized in this report, and concerns operations and waste disposal practices at the former Martin Company Middle River nuclear facilities.

- Information regarding the former uses of Building KQ was not identified in the records reviewed. A building layout included with the demolition specifications for Building KQ indicates two storage tanks of unknown volume and contents were inside the building.

- A ground-surface scan for gamma radiation was performed in the investigation area that included the former radiological research facilities. The gamma scan was completed as a precaution for the health and safety of field-investigation personnel. Gamma results were consistent with background readings; no elevated gamma readings were identified.

- A geophysical survey was conducted over an approximate four-acre area corresponding to the accessible areas of the former Greater Strawberry Point maintenance, storage, and nuclear research facilities. The survey included electromagnetic (EM-61) and ground-penetrating radar (GPR) reconnaissance of the area.

- EM-61 data indicate numerous small or insignificant subsurface anomalies, likely representative of scattered metallic debris in fill or discarded pipe remnants. Several larger or regularly shaped anomalies were also imaged using ground-penetrating radar to help determine their shape and orientation. Of the anomalies scanned with ground-penetrating radar, four were identified with possible correlation to former buildings or utilities.

- One of the anomalies (Anomaly 1) is in the grassy field between Taxiway F and the Lockheed Martin corporate hangar. Anomaly 1 is near the former location of a maintenance storage building and may represent a buried wall or building remnant.

- Three anomalies (Anomalies 2 through 4) are in a raised-soil berm between the stormwater-detention basin and the wooded areas in northern Greater Strawberry Point. Anomaly 2 has a radar signature indicative of a piece of broken pipe, and the Anomaly 3 radar image suggests two rounded or semi-cylindrical objects, each approximately 1.5-feet-wide across their short axes. Anomaly 4 resembles possible construction or demolition debris. Anomalies 3 and 4 are close to the former Building KQ location.

Re: Request for Information under Freedom of Information Act (FOIA)/PIA
NRC records for Martin State Airport, 701 Wilson Point Road, Baltimore, Maryland 21220

Dear Sir or Madam:

This is a request under the Freedom of Information Act/Privacy Act (FOIA/PA) 5 U.S.C. 552). We are currently contracted by Lockheed Martin to review available records regarding prior operations and radioactive material handling at the above-referenced study area.

Because there have been many owners and license numbers associated with the facilities at Martin State Airport, we submit by Attachment Table 1 to be used to guide FOIA record searches for this request. The requested records are itemized by by facility name, address, license, owner, and keywords. We are interested in obtaining copies of records for all of the licenses referenced in Table 1 for the various addresses and tenants. (Note we are not requesting records specific to the separate Martin Company licensee address of 2323 Eastern Blvd. Baltimore, MD, but there may be some overlap in the records for the requested license numbers). The license information of we seek may contain one or more of the key words in Table 1. We are interested in reports, license amendments, applications, surveys, radiological health records, site inspections, and particularly maps or floor plans that may be contained in any of these records. Also of interest would be shipping and disposal records, if any, for the radiological wastes (e.g., filters, etc.) generated in any of these facilities or under any of the requested licenses.

If you have any questions concerning this request, please contact the undersigned at (301) 523-3018, or email me at Amy.McGivney@tetratech.com. We are willing to pay fees applicable to the processing of this request, however, please notify me in writing so the expense can be approved.

Sincerely,

Amy McGivney
Project Manager

From:	Burkhalter, Cornelia
To:	McGivney, Amy
Cc:	Burkhalter, Cornelia; FOIA Resource
Subject:	FOIA 2014-0087 FEE ESTIMATE
Date:	Tuesday, December 31, 2013 11:55:03 AM

Dear Ms. McGivney.

We have received the cost estimate for the search and review time of your FOIA case referenced above which was dated December 17, 2013. Region 1 has indicated that a total of 15 hours of search time, 44 hours of review time will be necessary to complete your request, which is expected to result in approximately 3000 pages.

Additionally, FSME has indicated that a total of 1 professional hour of search time, 30 minutes of clerical search time, and 1 hour of review time will be necessary to complete your request, which is expected to result in approximately 20 pages of records.

Because you were determined to be a "Commercial" requester, you will be responsible for all search, review, and duplication fees. Duplication costs may be reduced by requesting records electronically.

As such, your fee costs are as follows: 16 hours of professional search @ $56.36/hour plus 30 minutes of clerical search @ $25.16/hour = $914.34, 45 hours of professional review @ $56.36/hour = $2,536.20 and 3020 pages of duplication @ .20/page = $604.00. As such, the total fee estimate for processing your request is $4,054.54.

Pursuant to 10 C.F.R. 9.40(e), we will not continue processing your request until we receive a response from you of your willingness to pay the above-referenced fee. Additionally, because the estimated fee exceeds $250, the NRC will not process your request without the advance payment of the estimated fee.

If we have not received a response from you within 10 business days of this email, we will administratively close your request. You also may narrow the scope of your request to reduce both the estimated search and review fees associated with processing your request.

NRC FORM 509
(06-2013)

U. S. NUCLEAR REGULATORY COMMISSION
APPROVED BY OMB: 3150-0043
EXPIRES: (12/31/2014)

REQUEST NUMBER
FOIA/PA - 2014 - 0087

DATE

STATEMENT OF ESTIMATED FEES FOR FREEDOM OF INFORMATION ACT (FOIA) REQUEST

REQUESTER	NRC CONTACT	TELEPHONE
Amy McGivney	Cornelia Burkhalter	(301) 415-6600

Pursuant to the NRC's regulations, 10 CFR 9.40, 52 FR 49350, the NRC notifies a requester when estimated applicable fees exceed $25.00 or a limit stated in an FOIA request. The estimated fees for processing your FOIA request are noted below. If you wish to re-scope your request to reduce fees, you may telephone the NRC contact identified above to discuss re-scoping the request. Otherwise, please provide a written response on required action noted below. If the NRC does not receive notice from you on re-scoping your request or the required written response within 10 working days from the date of this notice, the NRC will presume that you have no further interest in NRC processing your request and will close the file on your request.

ESTIMATED FEES

SEARCH	$ 422.70	7.5 hours @ $56.36
REVIEW	$ 309.98	5.5 hours @ $56.36
DUPLICATION *	$ 206.60	1033 pages @ .20 per page
TOTAL	$ 939.28	

* Duplication estimate is based on the assumption that you want copies of disclosed records mailed directly to you. Please specify paper copy or a CD-Rom. If you choose a CD-Rom, the cost will be the cost of the CD-Rom to the NRC. If you prefer, the NRC will make disclosed records available, if appropriate, at the NRC Electronic Reading Room accessible from NRC's web site at http://www.nrc.gov/reading-rm.html. Please note your preference in the Response section below.

☑ Please note the comments provided on the attached NRC Form 509A.

☐ Your request for a waiver or reduction of fees does not provide sufficient information under 10 CFR 9.41 for the NRC to make a determination to waive or reduce fees. If you want the NRC to consider this matter further, please submit a written request pursuant to 10 CFR 9.41 within 10 working days from the receipt of this notice.

REQUIRED ACTION

☑ Please agree by signing below to pay fees as high as estimated by signing and dating the Response section of this form and returning the form to the NRC contact identified above at the U.S. Nuclear Regulatory Commission, Washington, DC, 20555-0001, or by fax to (301) 415-5130, within 10 working days from the date of this notice.

☐ Please provide an advance payment of the estimated fees by one of the methods described on the attached NRC Form 509A within 10 working days from the date of this notice. Any overpayment of fees will be refunded to you.

RESPONSE

As required above, I agree to pay fees as high as estimated. I agree to pay estimated search fees even if the NRC conducts an unsuccessful search for responsive records or determines records located are exempt from disclosure. I prefer that copies of disclosed records be provided as stated below.

☐ Mailed directly to me. ☐ Placed in the NRC Electronic Reading Room.

☐ Paper copy ☐ CD-Rom

SIGNATURE - FOIA/PA REQUESTER	DATE

NRC FORM 509 (06-2013)

Estimated burden per response to comply with this mandatory collection request: 6 minutes. This form is used to notify a requester of the amount of the estimated fees and to obtain the requester's agreement to pay the fees. Send comments regarding burden estimate to the FOIA, Privacy, and Information Collections Branch (T-5 F53), U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001, or by internet e-mail to Infocollects.Resource@nrc.gov, and to the Desk Officer, Office of Information and Regulatory Affairs, NEOB-10202, (3150-0043), Office of Management and Budget, Washington, DC20503. If a means used to impose an information collection does not display a currently valid OMB control number, the NRC may not conduct or sponsor, and a person is not required to respond to, the information collection.

NRC FORM 629 (11-2013) U.S. NUCLEAR REGULATORY COMMISSION

AUTHORIZATION FOR PAYMENT BY CREDIT CARD

APPROVED BY OMB: NO. 3150-0190 EXPIRES: 06/30/2014

Estimated burden per response to comply with this voluntary collection request: 5 minutes. Requested information will allow respondents to transfer funds electronically. Send comments regarding burden estimate to the FOIA, Privacy, and Information Collections Branch (T-5 F53), U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001, or by internet e-mail to Infocollects.Resource@nrc.gov, and to the Desk Officer, Office of Information and Regulatory Affairs, NEOB-10202, (3150-0190), Office of Management and Budget, Washington, DC 20503. If a means used to impose an information collection does not display a currently valid OMB control number, the NRC may not conduct or sponsor, and a person is not required to respond to, the information collection.

The NRC is currently accepting credit card payment of fees and other debts. If you wish to pay by credit card, complete the authorization below. If you have any questions, contact NRC's collection service provider, DEVA and Associates at (301) 415-3878.

PRIVACY ACT STATEMENT
NRC FORM 629
AUTHORIZATION FOR PAYMENT BY CREDIT CARD

Pursuant to 5 U.S.C. 552a(e)(3), enacted into law by Section 3 of the Privacy Act of 1974 (Public Law 93-579), the following statement is furnished to individuals who supply information to the U.S. Nuclear Regulatory Commission (NRC) on NRC Form 629. This information is maintained as part of a system of records designated as NRC-32 and described at 77 *Federal Register* 67225 (November 8, 2012), or the most recent *Federal Register* publication of the NRC's "Republication of Systems of Records Notices" that is available in the NRC's Agencywide Documents Access and Management System.

1. **AUTHORITY:** 5 U.S.C. 552a; 5 U.S.C. 5514; 15 U.S.C. 1681; 26 U.S.C. 6103; 31 U.S.C. Chapter 37; 31 U.S.C. 6501-6508; 42 U.S.C. 2201; 42 U.S.C. 5841; 31 CFR 900-904; 10 CFR Parts 15, 16, 170, 171; Executive Order (E.O.) 9397, as amended by E.O. 13478; and E.O. 12731.

2. **PRINCIPAL PURPOSE(S):** To collect credit card account information and provide authorization for its use to collect a payment or debt.

3. **ROUTINE USE(S):** Information contained in this system may be disclosed to debt collection contractors or to other Federal agencies for the purpose of collecting and reporting on delinquent debts and to banks enrolled in the Automated Clearinghouse (ACH) Network to collect a payment or debt when the individual has given his or her authorization for this purpose. Information may be disclosed in accordance with any of the Routine Uses listed in the Prefatory Statement of General Routine Uses, including to an appropriate Federal, State, local or Foreign agency in the event the information indicates a violation or potential violation of law; in the course of an administrative or judicial proceeding; to an appropriate Federal, State, local and Foreign agency to the extent relevant and necessary for an NRC decision about you or to the extent relevant and necessary for that agency's decision about you; in the course of discovery under a protective order issued by a court of competent jurisdiction and in presenting evidence; to a Congressional office to respond to their inquiry made at your request; to NRC-paid experts, consultants, and others under contract with the NRC, on a need-to-know basis; and to appropriate persons and entities for purposes of response and remedial efforts in the event of a suspected or confirmed breach of data from this system of records.

4. **WHETHER DISCLOSURE IS MANDATORY OR VOLUNTARY AND EFFECT ON INDIVIDUAL OF NOT PROVIDING INFORMATION:** Providing this information is voluntary. However, not providing the requested information will not provide the NRC the information and authorization required to use your credit card to collect a payment or debt.

5. **SYSTEM MANAGER(S) AND ADDRESS:** Controller, Division of the Controller, Office of the Chief Financial Officer, U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001.

FOIA/PA-2014-00087

Amy McGivney
Tetra Tech Inc.
20251 Century Blvd., Suite 200
Germantown, MD 20874-7114

Dear Requester:

We received your Freedom of Information Act/Privacy Act (FOIA/PA) request on December 17, 2013.

Your request has been assigned the following reference number that you should use in any future communications with us about your request: **FOIA/PA-2014-00087**

To ensure the most equitable treatment possible of all requesters, the NRC processes requests on a first-in, first-out basis, using a multiple track system based upon the estimated time it will take to process the request. Based on your description of the records you are seeking, we estimate completion of your request will take more than 20 working days. We will advise you of any change in the estimated time to complete your request.

Due to the unexpected events in Japan in March 2011, the NRC is processing a larger than normal volume of FOIA requests including some that have qualified for expedited processing and have therefore been placed at the front of the queue. We are doing our best to process all requests in a timely manner but our response times are being affected. We appreciate your understanding.

For purposes of assessing fees in accordance with our regulations (10 CFR 9.33), we have placed your request in the following category: **Commercial.** If applicable, you will be charged appropriate fees for: **Search, Review, & Duplication of Records.**

A sheet has been enclosed that explains in detail the fee charges that may be applicable. **Please do not submit any payment unless we notify you to do so.**

The following person is the FOIA/PA Specialist who has been assigned responsibility for your request: **Cornelia Burkhalter** at **301-415-6600.**

If you have questions on any matters concerning your FOIA/PA request please feel free to contact the assigned FOIA/PA Specialist or me at (301) 415-7169.

Sincerely,

/S/

Donna L. Sealing
FOIA/Privacy Act Officer
Office of Information Services

Enclosures:
Incoming Request
Explanation of Fees

EXPLANATION OF FEES

Requester Fee Categories

Commercial: Fees are charged for document search, duplication, and review, when records are requested for commercial purposes. Fees (above the minimum fee charge) cannot be waived for this category of requester.

Educational, Non-Commercial Scientific, News Media and Privacy Act: Fees may be charged only for document duplication when records are not sought for commercial use and the request is made by an Educational or Non-Commercial Scientific Institution, whose purpose is scholarly or scientific research; or a Representative of the News Media; or a person requesting his/her own records that are in a Privacy Act system of records. No fee is charged for the first one hundred pages of duplication for this category of requester.

Non-Excepted: For any request not described above (Non-Excepted), fees may be charged for document search and duplication. No fee is charged for the first two hours of search time or for the first one hundred pages of duplication for this category of requester.

Fee Schedules

Fee schedules provide only for the recovery of the direct costs of search, duplication, or review. Review costs include only the costs for initial examination of a document to determine whether it must be disclosed and to determine whether to withhold portions that are exempt from disclosure. The fee schedule is as follows:

Search & Review Conducted By	**Rate**	
! SES/COMMISSIONER	$90.53/hour	(ES-maximum)
! PROFESSIONAL	$56.36/hour	(GG-13, Step 6)
! CLERICAL	$25.16/hour	(GG-7, Step 6)
Duplication Charges	$.20 per page	

Fees for non-standard search or duplication will be charged at the actual cost (e.g. providing copying of audio tapes or conducting computer searches).

Minimum Fee: No fee will be charged unless the fee is equal to or greater than $25.00.

When to Pay Fees

If we estimate that fees will not exceed $25.00 or you have stated in your request a higher amount that you are willing to pay, we assume your willingness to pay up to $25 or the amount stipulated and you will be billed after we have completed your request.

If we estimate that fees will exceed $25.00 or any amount that has been stated by you in your request, we will not proceed with your request until we have notified you and obtained your agreement to pay the estimated fees.

If we estimate fees will exceed $250, you will be required to pay the estimated fees in advance before we proceed further with your request. If, while processing your request, we find that the actual fees exceed the estimated fee, we will obtain your consent to pay the additional fees before continuing to process your request. If the actual fees to process your request are less than any advance payment you have made, you will be refunded the overpayment amount.

Fee Waivers

A waiver or reduction of fees may be granted for furnishing documents if a requester, by fully addressing the eight factors in 10 CFR 9.41, clearly demonstrates that disclosure of the information is in the public interest because it is likely to contribute significantly to public understanding of the operations or activities of the government and is not primarily in the commercial interest of the requester.

Subject: FEE ESTIMATE FOR FOIA 2014-0087

Dear Ms. McGivney.

Please review the attached fee estimate carefully. A copy of your request is also attached. The fee amount is based on 7.5 hours of professional search time, 5.5 hours of professional review time and 1033 pages of duplication.

If you agree to pay the fees, please sign the form as indicated and return via fax or e-mail within 10 business days or by January 31, 2013. If a response is not received within 10 business days from the date of this notice, your request will be closed.

If you have any questions, please contact me via telephone or e-mail.

Thank you.

Re: Request for Information under Freedom of Information Act (FOIA)/PIA
NRC records for Martin State Airport, 701 Wilson Point Road, Baltimore, Maryland 21220

Dear Sir or Madam:

This is a request under the Freedom of Information Act/Privacy Act (FOIA/PA) 5 U.S.C. 552). We are currently contracted by Lockheed Martin to review available records regarding prior operations and radioactive material handling at the above-referenced study area.

Because there have been many owners and license numbers associated with the facilities at Martin State Airport, we submit by Attachment Table 1 to be used to guide FOIA record searches for this request. The requested records are itemized by by facility name, address, license, owner, and keywords. We are interested in obtaining copies of records for all of the licenses referenced in Table 1 for the various addresses and tenants. (Note we are not requesting records specific to the separate Martin Company licensee address of 2323 Eastern Blvd. Baltimore, MD, but there may be some overlap in the records for the requested license numbers). The license information of we seek may contain one or more of the key words in Table 1. We are interested in reports, license amendments, applications, surveys, radiological health records, site inspections, and particularly maps or floor plans that may be contained in any of these records. Also of interest would be shipping and disposal records, if any, for the radiological wastes (e.g., filters, etc.) generated in any of these facilities or under any of the requested licenses.

If you have any questions concerning this request, please contact the undersigned at (301) 523-3018, or email me at Amy.McGivney@tetratech.com. We are willing to pay fees applicable to the processing of this request, however, please notify me in writing so the expense can be approved.

Sincerely,

Amy McGivney
Project Manager

Report of Observations

Type of Inspection/Observations: _____ Date 85/02/13

Facility Name: Glenn L. Martin State Airport, Box 1, 701 Wilson Point Road, Balto Md 21220

Remarks: John Beazley, Barry Chambers, Valer. Doyle, and Mike Griffen met with J. Leonard Wood and Jake West at the Martin State Airport office on Feb 13 at 1300hrs J. Leonard Wood is the Martin State Airport manager. John Beazley, Barry Chambers, Valeri Doyle, and Mike Griffen accompanied Leonard Wood on a tour of the Facility. [redacted] Tech Sgt. Charles Smith of the Air Guard accompanied us when touring the facility east of the air strip.

From the beach along Frog Motar Creek, concrete rubble, corrugated steel pipe, and a couple of drums were observed in the side of the Fill. Indiscriminate dumping was observed at this site in the past as noted in the inspection report of Sept 16, 1981 by James Curtis from this office.

West of the airstrip several areas of dumping were observed. A deer carcass, cylinders of refrigerant, assorted junk, and rubble were observed. Thirty nine drums were observed by the KJ building; some, but not all, of the drums were empty. One empty drum, denatured ethanol, had a 'Tilly Chemical' label. Drums were observed in the fill area near the KJ building, again demonstrating the indiscriminate waste handling practices at this facility. Photographs were taken by Barry Chambers during this survey.

Mr Griffen discussed the ground water contamination with Mr. Wood and informed Mr. Wood that the airport will have to contract out for surveying and analysis regarding the ground water contamination. Since the Maryland Environmental Service handles the sampling required in the airport's NPDES permit and operates the waste treatment plant at the airport, the recommendation that MES be used as consultant was made.

Mr. Chambers recommends that this site be put on a remedial clean up list such as the State Superfund list and/or the Federal Superfund list.

Mr. John Beazley

Thru: Mr. John Koontz

TO Mr. Frank Henderson From Mr. Paul Thompson Date 2/26/85

Subject Glenn L. Martin State Airport, Baltimore County

Staff investigation of this site indicates improper waste disposal practice.

These include:

1. acid and waste oil disposal pits (at least 4)
2. landfilling (indiscriminate)
3. explosives disposal (deactivated bombs, we're told!) into dredge holes in Frog Mortar Creek.

Private labs show trace organic (L 1-ppb range) contamination of two potable wells on site, yet sampling does not substantiate this.

Therefore, this site should be added to your next published list of sites for future assessment and/or investigation.

Dear Ms McGivney,

The Maryland Department of the Environment (MDE) received your recent request for information under the Public Information Act (PIA). Your request has been assigned the tracking number listed above. Please use this number in all communications referring to this request.

After the search for information is complete, I will notify you as to whether or not pertinent records exist. We address PIA requests in the order in which we receive them. There may be fees associated with the search or production of documents. If files exist, I will notify you of an estimated cost and you will be required to provide payment authorization before documents will be produced or sent to you.

You may find it helpful to review the following information regarding the PIA process:

To: "MDE.PIA@maryland.gov" <MDE.PIA@maryland.gov>

Dear Sir or Madam,

This email is to request a search and retrieval of specific MDE Radiological Health archived records under the Public Information Act. Tetra Tech is conducting environmental due diligence research for a property in Middle River, Maryland on behalf of a former property owner. The property was located on a former dirt road at the current Martin State Airport, 701 Wilson Point Road, Middle River, Baltimore County, Maryland.

The property of interest may be identified by the above address (Martin State Airport) in MDE records, or listed by name under former tenants of two nuclear fuel research facilities which previously operated at said location between 1957 and 1966, approximately. Former tenant names include Martin Company, Ebasco, Raytheon, Radioisotopes, Inc, and Isotopes, Inc. The facilities were known as the Martin Critical Facility, or Critical Test Facility, and the Radioisotope Lab. After termination of Nuclear Regulatory Commission (NRC) Licenses (est. 1965-1970), these buildings were abandoned for several years before being demolished around 2000 by the State of Maryland (Maryland Aviation Administration). In 1989, while the buildings were still present, MDE was involved in a joint inspection of the facilities with NRC to help determine suitability for unrestricted use. Tetra Tech reviewed a State of Maryland report (report MD-304, "A Preliminary Assessment of Martin State Airport, Middle River, Maryland") prepared by the Maryland Hazardous and Solid Waste Management Administration (MDE/HSWMA) and dated March 1989, which contains reference to two memoranda: (1) Memo dated March 30, 1989 from MDE/HSWMA to the Hazardous Waste Enforcement Division, concerning materials in storage in the abandoned, above-referenced buildings; and (2) Memo dated March 31, 1989 from MDE/HSWMA to the MDE Toxic, Environmental Science and Health, Center for Radiological Health concerning lack of records of past generation and disposal of hazardous and radioactive waste from these facilities. By this PIA request, we are making specific request for these memoranda, any related correspondence or files, and information on the final disposition of these files. We also request any records you may have concerning the demolition of these facilities around 2000.

We sincerely appreciate your assistance with this request. I can be contacted at the number below for more information or with any questions.

Sincerely,
Amy McGivney

Subject: PIA Request - Hazardous waste records from 1989
Date: Thursday, January 16, 2014 5:28:00 PM

Dear Ms. Stephens,

This email is to request a search and retrieval of specific MDE Hazardous and Solid Waste division archived records under the Public Information Act. The subject request was also submitted to MDE's Radiological Health division and Colleen Williams referred my request to you. Tetra Tech is conducting environmental due diligence research for a property in Middle River, Maryland on behalf of a former property owner. The property was located on a former dirt road at the current Martin State Airport, 701 Wilson Point Road, Middle River, Baltimore County, Maryland.

The property of interest may be identified by the above address (Martin State Airport) in MDE records, or listed by name under former tenants of two nuclear fuel research facilities which previously operated at said location between 1957 and 1966, approximately. Former tenant names include Martin Company, Ebasco, Raytheon, Radioisotopes, Inc, and Isotopes, Inc. The facilities were known as the Martin Critical Facility, or Critical Test Facility, and the Radioisotope Lab. After termination of Nuclear Regulatory Commission (NRC) Licenses (est. 1965-1970), these buildings were abandoned for several years before being demolished around 2000 by the State of Maryland (Maryland Aviation Administration). In 1989, while the buildings were still present, MDE was involved in a joint inspection of the facilities with NRC to help determine suitability for unrestricted use. Tetra Tech reviewed a State of Maryland report (report MD-304, "A Preliminary Assessment of Martin State Airport, Middle River, Maryland") prepared by the Maryland Hazardous and Solid Waste Management Administration (MDE/HSWMA) and dated March 1989, which contains reference to two memoranda: (1) Memo dated March 30, 1989 from MDE/HSWMA to the Hazardous Waste Enforcement Division, concerning materials in storage in the abandoned, above-referenced buildings; and (2) Memo dated March 31, 1989 from MDE/HSWMA to the MDE Toxic, Environmental Science and Health, Center for Radiological Health concerning lack of records of past generation and disposal of hazardous and radioactive waste from these facilities. By this PIA request, we are making specific request for these memoranda, any related correspondence or files, and information on the final disposition of these files. We also request any records you may have concerning the demolition of these facilities around 2000.

We sincerely appreciate your assistance with this request. I can be contacted at the number below for more information or with any questions.

Sincerely,
Amy McGivney

Subject: PIA Request - Radiological Health Division
Date: Wednesday, January 08, 2014 4:05:58 PM

Dear Sir or Madam,

This email is to request a search and retrieval of specific MDE Radiological Health archived records under the Public Information Act. Tetra Tech is conducting environmental due diligence research for a property in Middle River, Maryland on behalf of a former property owner. The property was located on a former dirt road at the current Martin State Airport, 701 Wilson Point Road, Middle River, Baltimore County, Maryland.

The property of interest may be identified by the above address (Martin State Airport) in MDE records, or listed by name under former tenants of two nuclear fuel research facilities which previously operated at said location between 1957 and 1966, approximately. Former tenant names include Martin Company, Ebasco, Raytheon, Radioisotopes, Inc, and Isotopes, Inc. The facilities were known as the Martin Critical Facility, or Critical Test Facility, and the Radioisotope Lab. After termination of Nuclear Regulatory Commission (NRC) Licenses (est. 1965-1970), these buildings were abandoned for several years before being demolished around 2000 by the State of Maryland (Maryland Aviation Administration). In 1989, while the buildings were still present, MDE was involved in a joint inspection of the facilities with NRC to help determine suitability for unrestricted use. Tetra Tech reviewed a State of Maryland report (report MD-304, "A Preliminary Assessment of Martin State Airport, Middle River, Maryland") prepared by the Maryland Hazardous and Solid Waste Management Administration (MDE/HSWMA) and dated March 1989, which contains reference to two memoranda: (1) Memo dated March 30, 1989 from MDE/HSWMA to the Hazardous Waste Enforcement Division, concerning materials in storage in the abandoned, above-referenced buildings; and (2) Memo dated March 31, 1989 from MDE/HSWMA to the MDE Toxic, Environmental Science and Health, Center for Radiological Health concerning lack of records of past generation and disposal of hazardous and radioactive waste from these facilities. By this PIA request, we are making specific request for these memoranda, any related correspondence or files, and information on the final disposition of these files. We also request any records you may have concerning the demolition of these facilities around 2000.

We sincerely appreciate your assistance with this request. I can be contacted at the number below for more information or with any questions.

Sincerely,
Amy McGivney

Dear Ms McGivney,

The Maryland Department of the Environment (MDE) received your recent request for information under the Public Information Act (PIA). After a thorough search of all available information, the MDE Air & Radiation Management Administration found no records responsive to your request.

I suggest that you submit your request for information to Maria Stephens in MDE's Land Administration, since that is the group that oversees Hazardous and Solid Waste. No charges were incurred.

Thank you,

Colleen Donnelly Williams

TETRA TECH

January 12, 2012

FOIA/PA REQUEST
Case No.: 2012-0117
Date Rec'd: 1-20-12
Specialist: Kilgore
Related Case:

U.S. Nuclear Regulatory Commission
Office of Information Services
Mail Stop T5-F11
Washington, DC 20555-0001
Attention: Donna Sealing, FOIA/Privacy Act Officer

Re: Request for Information "Building D" at "Block E"
Middle River Facility and Martin State Airport,
Baltimore, Maryland 21220

Dear Sir or Madam:

This is a request under the Freedom of Information Act/Privacy Act (FOIA/PA) 5 U.S.C. 552). This is a supplement to prior requests #2006-0006 and #2008-0059. We are currently contracted by Lockheed Martin to review available records regarding past hazardous substance usage and waste generation, including radioactive materials, at the above-referenced study area. Of particular interest would be ***records (likely dated 1957 to 1970) to describe the locales and means of storage and disposal of source materials governed under the licenses, and any notices of violation***, for the former NRC License Nos. 19-01398-32, SNM-11, SNM-53, SNM-1192, and STB-187. Also of interest are documents that itemize and/or list quantities of chemicals and radioactive materials that were obtained, stored or used, and quantities of hazardous or radioactive wastes generated, shipped and/or disposed in connection with the facility activities under licenses listed above. Additionally, as the above-referenced licenses (reviewed by our staff previously) pertained to manufacturing and research processes, in this letter we are requesting that NRC identify any additional licenses held by the subject facility for the storage, use, testing, and/or and handling of radioactive instruments and equipment (e.g., night-vision goggles, aviation and aeronautical dials and gages, etc.) from the 1950s to 1980s, along with related records.

The current address for the Middle River Facility is *2323 Eastern Boulevard* in Middle River (Baltimore), Maryland. Previous NRC correspondence for this address also referenced the site as the *Martin State Airport at 701 Wilson Point Road*, Baltimore, Maryland. The Middle River facility was formerly known as *Chesapeake Industrial Park and Chesapeake Park Plaza*, and former tenants at the effective time of the license included *Martin Marietta, Middle River Aircraft Systems, and the Martin Company.*

TETRA TECH

The former Building D was approved for unrestricted use in an NRC Region I Inspection Report (No. 94-001) dated January 25, 1995. Through previous FOIA Request #PA-2008-0006, we already have obtained copies of documents pertaining to the decommissioning (in 1970) and related inspections, as well as the permit applications and amendments. **We do not wish to retrieve records that are duplicates with those obtained in the previous request.** The specific records of interest were highlighted above.

If you have any questions concerning this request, please contact the undersigned at (301) 523-3018, or email me at Amy.Stattel@tetratech.com. We are willing to pay fees applicable to the processing of this request, however, please notify me in writing so the expense can be approved.

Sincerely,

Amy Stattel

GUIDE PAGE - REPORT TES-3210

This is the Guide Page to update report TES-3210 to Revision 2, December 1991.

1. Replace "Title Page" with new title page

2. Add "Preface to Revision 2" - pages vi-a and vi-b

3. Replace "Table of Contents" pages vii and viii

4. Add Appendix E: "Operating Procedures," and Appendix F "Acceptance Test and Maintenance Program," pages E-1 thru E-5 and page F1 at end of report (after Appendix D, "Specification for Shield and Generator Housing Materials").

RESUBMITTAL OF PRIOR APPLICATIONS AND SUPPLEMENTS FOR APPROVAL TO TRANSPORT THE SENTINEL (LCG) - 25C RADIOISOTOPE THERMOELECTRIC GENERATOR AS A TYPE B ( ) PACKAGE

TES-3210

AUGUST 1986

REVISION 1

OCTOBER 1986

REVISION 2

DECEMBER 1991

TELEDYNE ENERGY SYSTEMS
110 W. TIMONIUM ROAD
TIMONIUM, MARYLAND 21093

PREFACE TO REVISION 2

Revision 2 is in response to a NRC request* to supply additional information to include specific specific sections on operating procedures and maintenance program. The applicability of these two sections is addressed below.

OPERATING PROCEDURES

The intent of this chapter in the NRC Regulatory Guide 7.9 "Standard Format and Content of Part 71 Applications for Approval of Packaging of Type B, Large Quantity and Fissile Radioactive Material" is apparently to provide procedures for use in the loading and unloading of a typical "package" such as a shipping cask used to transport radioactive materials. A radioisotope fueled thermoelectric generator (RTG), however, is designed to convert the energy given up by the radioisotope's decay directly to electricity and hence, is useful only when loaded.

The Sentinel-25 series packages (RTGs) have been loaded or "fueled" at Oak Ridge National Laboratory (ORNL) and each RTG will remain "fueled" or loaded throughout its useful lifetime. If, and when, at the end of the RTG's useful life, the decision is made to "de-fuel" or unload the RTG, procedures will be developed based on the facilities to be used. Obviously, it is not possible to ship and "empty" package for these same reasons. The procedures for loading, unloading and transport of an empty package as described in the Regulatory Guide, therefore, are not applicable to an RTG. There are, however, procedures that must be followed to properly handle and transport an RTG and these procedures are outlined in new Appendix E: "Operating Procedures."

ACCEPTANCE TESTS AND MAINTENANCE PROGRAM

Again, the NRC Regulatory Guide, under the heading of "acceptance tests" requests that the applicant discuss those tests to be performed prior to the first use of a package. All of the Sentinel-25 series packages were fabricated and inspected many years ago. Even though tests were performed to assure that the radioisotopic heat sources were leak tight and that the radiation shielding is adequate to meet the requirements of 10 CFR Part 71, no additional units may be built and therefore this section is not applicable. Additionally, an RTG is designed to be maintenance free such that the only maintenance required is related to the shipping pallet and the associated attaching hardware, these items are discussed in new Appenedix F: "Acceptance Test and Maintenance Program."

---

* U.S. NRC letter SGTB:MGB 71-4888 dated 04 November 1991 from Charles E. MacDonald to John F. Vogt (TES) with enclosure.

APPENDIX E

OPERATING PROCEDURES

DECEMBER 1991

The operating procedures discussed in this Appendix pertain to generator handling and transportation requirements.

1. RTG Handling

The SENTINEL 25 Series of RTGs are certified for shipment in vessels, cargo-only aircraft, rail cars and motor vehicles. They may be shipped without any special shipping container, but they must be attached to the steel pallets provided with the generator. The RTG is designed to be handled by fork-lift truck, with the forks fully engaged under the pallet, or by an overhead hoist or crane attached to a suitable sling. The generator is designed to be lifted by any 2 of the lifting/tie-down lugs. The sling must have a safe working load of at least 6900 pounds (the weight of the RTG and pallet plus a handling load of 3 G's).

An RTG should be handled with reasonable care. The thermoelectric modules are relatively fragile and open or short circuits can develope if the RTG is handled roughly. RTGs should never be dropped or pulled along a surface. Forklift and crane operators should take care to set the units down gently.

2. RTG Preparation for Shipment

To prepare the RTG for shipment the following steps must be taken:

a. Insure that the finned radiator assembly is bolted to the RTG's lid. (It should not normally ever be removed.)

b. Insure that the "shorting plug" furnished with the RTG is installed, when the RTG is disconnected from its electrical load.

c. Insure that the RTG is properly installed on its steel shipping pallet and tied down with the hardware shown on Figure E-1. Note that the Sentinel 25C is the only RTG in the entire Sentinel 25 series of generators that is not bolted directly to the steel pallet but is attached by means of turnbuckles. The shipping pallet was modified by the user and the attaching hardware provided as "government furnished equipment." General arrangement of hardware, however, is shown in Figure E-1 and the torque should be limited to 85-90 foot pounds.

d. Health Physics personnel should verify that the radiation dose rates measured at the RTG surface and at one meter from the surface are in compliance with 10 CFR 71.47.

e. Health Physics personnel should wipe test the outer surface of the generator and shipping pallet to assure compliance with 10 CFR 71.87 (i), and license leak test requirements.

f. The RTG's were marked and labelled prior to their initial shipment. Verification should be made to assure that the nomenclature is legible.

Markings

The following markings are required by 49 CFR. Letters must be at least 1/2" high.

(1) "RADIOACTIVE MATERIAL, SPECIAL FORM, N.O.S."

(2) (Gross Weight)

(3) "TYPE B"

(4) "USA/4888/B ( )" for Sentinel 25 Series RTGs

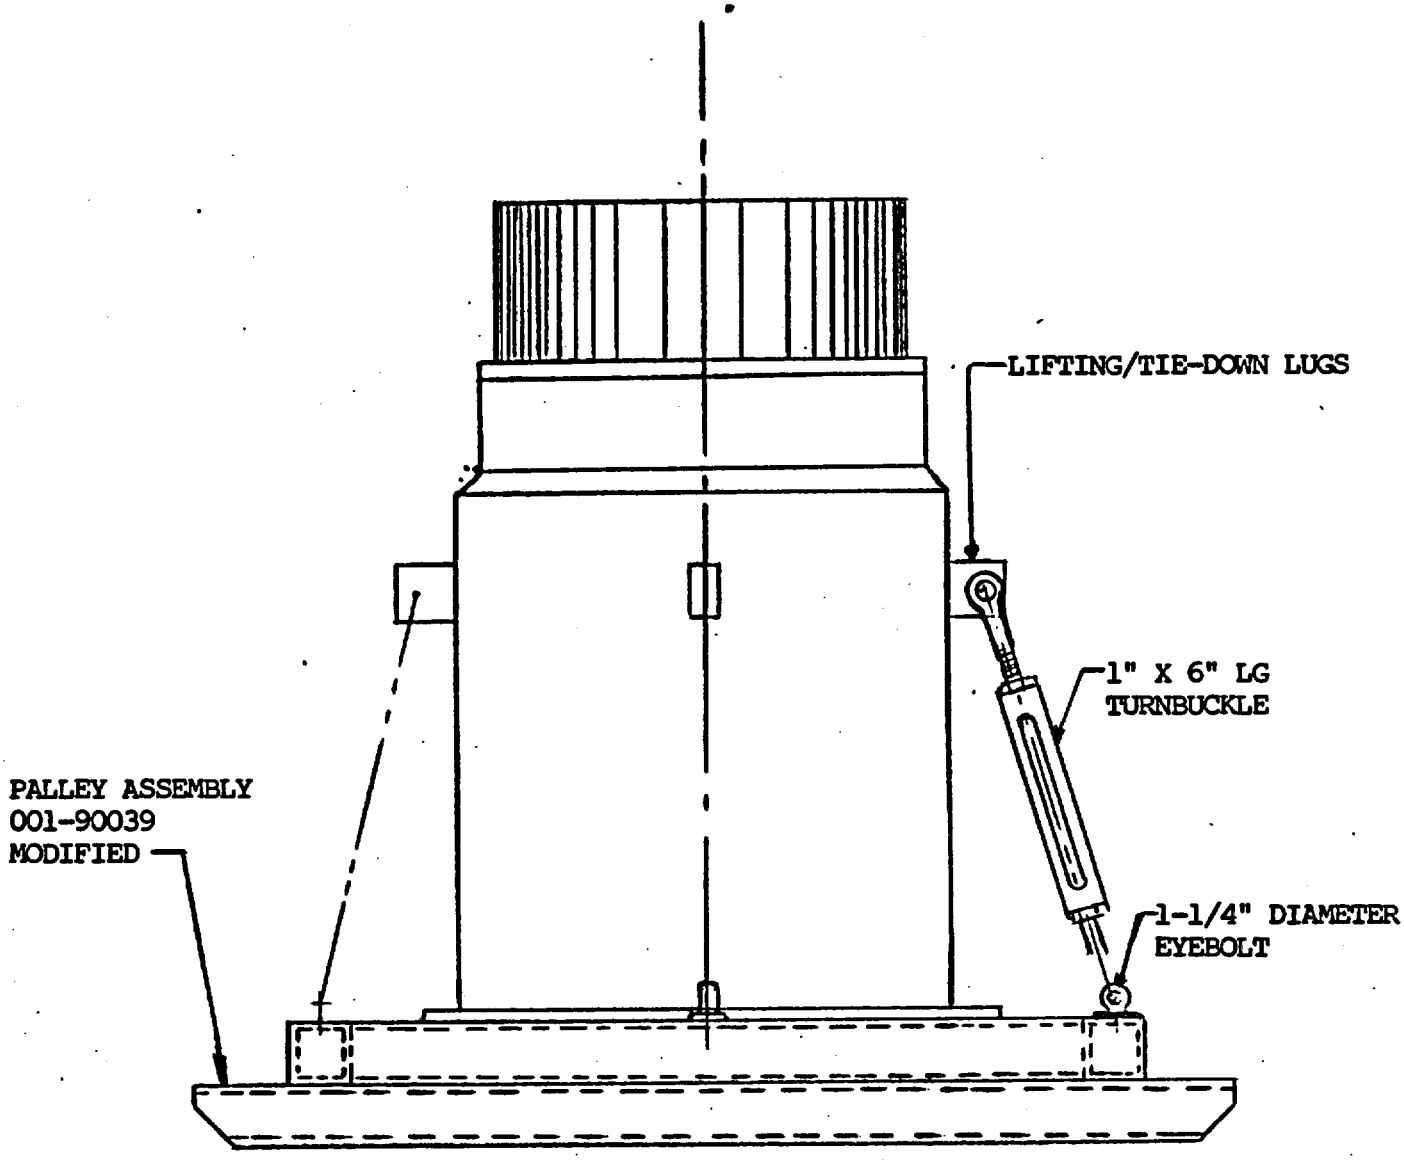

FIGURE E-1. SENTINEL 25C IN SHIPPING CONFIGURATION

(5) "UN 2974"

(6) (Model Number; e.g.: "SENTINEL 25F")

Labelling

Two "RADIOACTIVE-YELLOW III" labels are required on each RTG. They must be completed to show the radioisotope (strontium-90) curie content (as appropriate), and transport index (as appropriate) and are placed on opposite sides of generator.

The RTG, when loaded for shipment is to be tied down in a configuration similar to that shown in Figure E-2. In addition, the RTG must not be covered and should be kept at least one foot from bulkheads, other cargo and any other obstructions which might restrict the flow of air around the generator.

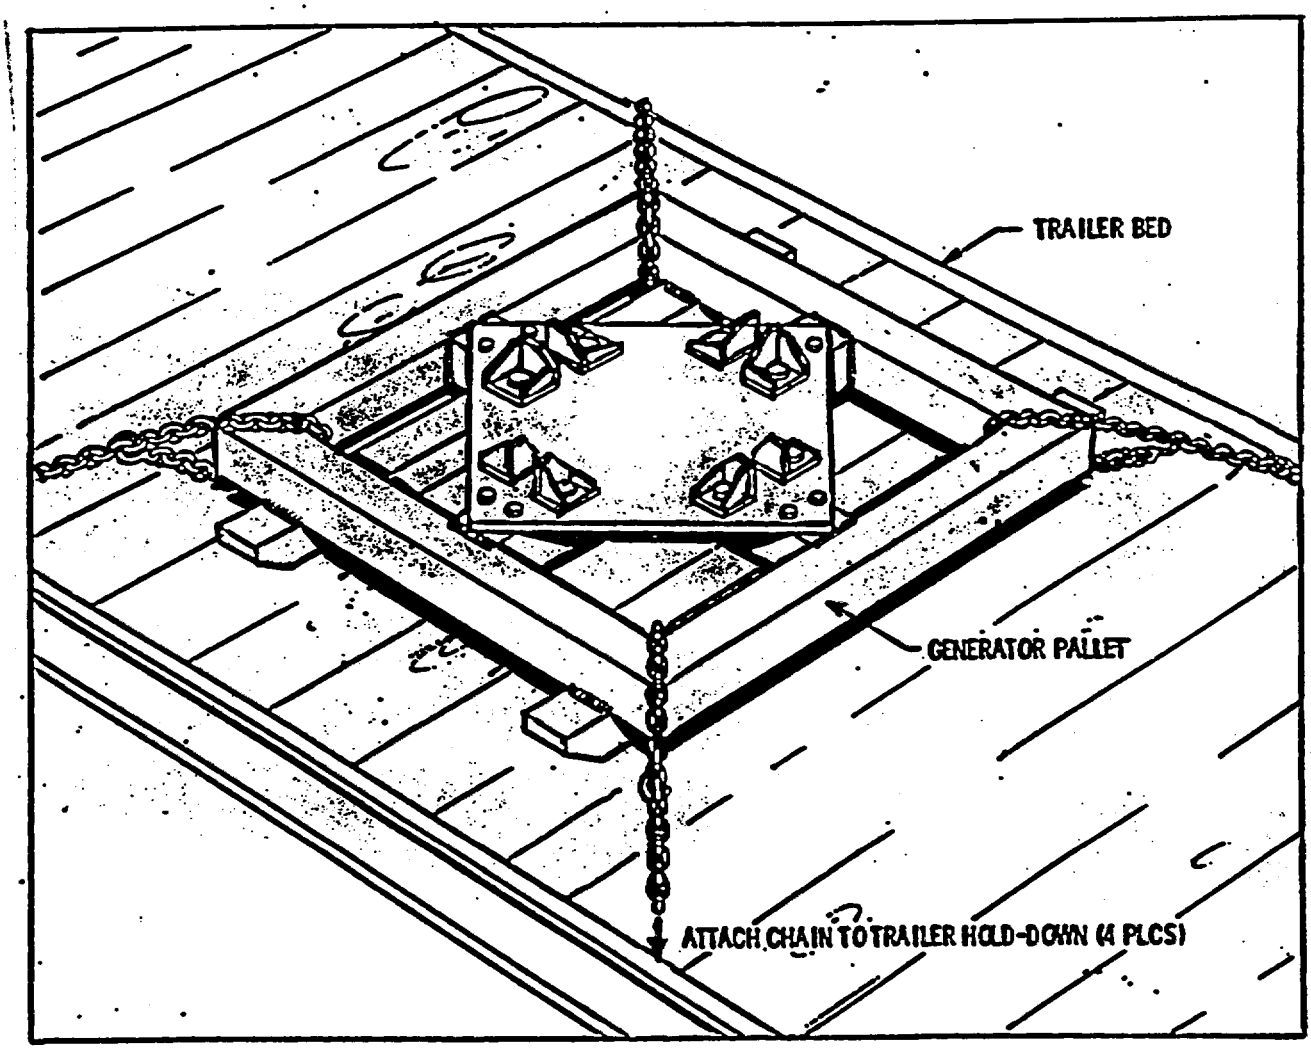

FIGURE E-2. PALLET TIE-DOWN CONFIGURATION

END OF APPENDIX E

APPENDIX F

ACCEPTANCE TEST AND MAINTENANCE PROGRAM

DECEMBER 1991

As discussed in the preface to Revision 2, there are no acceptance tests applicable to the SENTINEL 25 series of packages. In addition, the RTG is basically designed to be maintenance free due to its use primarily in remote, un-attended locations. This chapter deals with the very minor maintenance program required to ensure continued performance of the RTG package.

1. General Testing

There are no structural or pressure testing required to ensure the package performance. "Wipe" testing of the RTG's outer surface to check for the presence of removable radioactive contamination is required prior to the shipment of an RTG (see Chapter VIII). This test verifies that containment has not been breached since the previous shipment and is also the basis for demonstrating compliance with 10 CFR 71.87 (i).

2. Pallet

Prior to each shipment, as a minimum, the steel pallet should be visually inspected for evidence of rust, paint flaking and/or chipping and other signs of general deterioration, the pallet should be wire brushed and painted with one coat of primer and two finish coats of a good grade enamel paint when rusting is evident.

3. Hardware

The hardware that attaches the RTG to its shipping pallet (see Figure E-1) should be inspected prior to each shipment for signs of corrosion, structural damage and other forms of deterioration. The hardware must be replaced with new hardware if structural integrity is in doubt.

END OF APPENDIX F

MARTIN COMPANY

NUCLEAR
DIVISION
Baltimore,
Maryland

In reply refer to:
ACC-277

April 15, 1964

Material Licensing Division
U. S. Atomic Energy Commission
Washington, D. C.

Attention: Mr. Lyall E. Johnson, Acting Director
Material Licensing Division

Subject: Renewal of Byproduct Material License 19-1398-29

Enclosure:
(1) Application for Byproduct Material License Form AEC-313 (6 copies)
(2) Radioisotopes Pilot Plant - Facility Design and Safety Evaluation MND-3137 (6 copies)
(3) Cell 4 Process Control Panel N-0009748 (6 copies)
(4) Cell and Isolation Concept for Cells 3 and 4 N-0009744 (6 copies)

Gentlemen:

We request that Byproduct Material License No. 19-1398-29, covering the operation of the Martin Marietta Corporation Pilot Plant at Quehanna, Pennsylvania utilized for the production of isotopic heat sources, be renewed.

We have compiled "Radioisotopes Pilot Plant - Facility Design and Safety Evaluation", MND-3137 in support of our request for license renewal. Chapter 3, Part 3.6 of MND-3137 "Reagents" sets forth classified information in connection with License No. 19-1398-29 and is being forwarded under separate cover.

B-69

We intend that "Radioisotopes Pilot Plant - Facility Design and Safety Evaluation", MND-3137, replace all previous submissions in connection with the existing byproduct license 19-1398-29 with the following exceptions:

(1) A Proposed Amendment to License 19-1398-29 submitted to you on April 1, 1964 covering the removal and disposal of the Stationary Overhead Transfer System.

(2) A proposed amendment to be submitted to you in the near future to obtain Commission approval for the rehabilitation of Cells 1 and 2.

Your approval of this submission is required no later than July 1, 1964 in order that we may resume production of heat sources at that time.

We will be happy to participate in any discussions you may desire and will contact your office in approximately two weeks to establish a firm meeting date to discuss any questions you may have concerning this submission. Please contact me on 301-687-3800, Extension 513 at any time if we can be of assistance in this matter.

Thank you for your early consideration of this matter and for the excellant cooperation of your personnel in past licensing actions.

Very truly yours,

C W Keller

ACKNOWLEDGEMENTS

This report has been prepared and edited by members of the Nuclear Safety Unit of the Martin Nuclear Division. In addition to those listed on the title page, R. Huebschman assisted in the early portion of the work. I. Gray also assisted the Unit in the beginning.

The work could not have been brought to a successful completion without the continued cooperation and assistance of the Quehanna Plant staff, including J. Cochran, Plant Manager, and M. Bowles. The latter, designated for liaison, worked closely with the Unit.

The chapter on health physics was prepared by R. Brisson, Supervisor of Health Physics, and J. Toennies. This group gave other valuable criticisms and suggestions.

The sections on shielding were prepared by D. C. Anderson, A. Spamer and K. Davenport of the Shielding Unit and they have reviewed other sections, as appropriate.

Dr. Merrill Eisenbud, Professor of Industrial Medicine has reviewed the report and made highly valued comments.

Figure 2.2 has been reproduced from the official state map of Pennsylvania by the kind permission of that state's Department of Highways. Figure 2.3 was prepared from a map of the United States Geological Survey.

FOREWORD

This report is submitted to the Division of Licensing and Regulation of the United States Atomic Energy Commission by the Nuclear Division of the Martin Company. It presents the plant design, process description and safety evaluation of the Radioisotopes Pilot Plant at Quehanna, Pennsylvania. It is presented in support of the Martin Company application for license to continue the production of radiostrontium fuel forms.

CHAPTER 1

INTRODUCTION

This summary report has been prepared by Martin Nuclear Division, Baltimore, Maryland, a division of Martin Marietta Corporation. It presents the plant design and production process of the Radioisotopes Pilot Plant at Quehanna, Pennsylvania, and provides a general safety evaluation of the facility and operation. The report is submitted to the United States Atomic Energy Commission in support of an application for license to continue processing multi-curie quantities of radiostrontium.

The Radioisotopes Pilot Plant has been operated by the Martin Company since July, 1962. In this time invaluable experience has been gained and much of this is reflected in the improvements in plant design, process equipment and procedures and safety provisions described in the present report.

The operations of the Radioisotopes Production Pilot Plant are directed to the production of radioisotopic sources of heat. Several generators employing such sources are now in use furnishing power for remotely-located automatically-reporting weather stations, navigation buoys, etc., and are contemplated for use in space vehicles. The requirements in these field are expected to utilize the full capacity of the Pilot Plants in the immediate future and to exceed it in the

near future.

The building in which the Radioisotopes Production Pilot Plant is located was constructed by the Curtiss-Wright Corporation in 1957 and presented to the Pennsylvania State University in September 1960. The Martin Company leases from the University which retains control of part of the building and monitors the liquid waste disposal to the streams.

CHAPTER 2

QUEHANNA SITE

The area within which the Martin Radioisotopes Pilot Plant is located is the former Curtiss-Wright Quehanna Research Facility, 45 miles northwest of State College in north-central Pennsylvania. It includes parts of Elk, Cameron, and Clearfield Counties. Figure 2.1 shows the area in relation to the State of Pennsylvania. This location is perhaps the most remote one for a nuclear facility in the eastern United States, since it is in a sparsely populated region and has an area of approximately 80 square miles. The nearest population centers, Sinnemahoning (population 300) and Karthaus (population 400), are nine miles from the site. This site is ideal for the hot cell operations with respect to its population, meteorologic and hydrologic characteristics. Its general features are representative of those of the Appalachian Plateau physiographic province. Radioisotope production has been carried out by the Martin Company on the site under license from the Atomic Energy Commission since 1962; previous to that reactor and nuclear facilities were operated by the Curtiss-Wright Corporation and the Pennsylvania State University. This study extends and brings up-to-date a previous site description (Reference 2.1)

The land is largely state forest and state gameland. Circles of 5, 10 and 25 mile radius have been superimposed on the map.

2.1.2 Exclusion Area

Figure 2.3 is a reproduction of a topographic map of the site area. The laboratory site is shown near the upper left corner of the map.

The exclusion area is defined as that area around the laboratory which is under control of the Martin Company and the Pennsylvania State University. The terms of the agreement between Martin and the University with respect to this exclusion area are described in Reference 2.2. The reference states that "all necessary steps" are being taken to assure that an exclusion area is maintained which will be satisfactory to Martin and the Atomic Energy Commission. Control is maintained around the facility via Cyclone fence and guard service.

2.2 Geography

2.2.1 Topography

The topography of the region is typical of the Appalachian Plateau; it is a relatively flat area at an average elevation of 2000 feet above mean sea level. The edge of the exclusion perimeter is incised by several gorges up to one-half mile in width and 1000 feet in depth which radiate from their origin near the center of the site.

2.2.2 Land Usage

The area is included in state forest land with a secondary growth of trees. In this area, there is seasonal

recreation activity especially hunting. Beyond the state forest land, within outlying townships, there is small-scale agricultural activity. Land usage is therefore quite limited.

2.3 Population Density and Distribution

The sparse population in its environs is perhaps the most favorable feature of the site. The state forest surrounding the facility has a low permanent population density. Within a 25 mile radius of the site, the population density is 27 individuals per square mile, with a total population within this zone of about 53,000.

The population within a 25 mile radius of the site is distributed into about 50 small villages with populations less than 1000 individuals (average 400), six small towns averaging 5000 individuals and a minimal number of outlying individual habitations. The total population of this zone has decreased by about 8000 during the past 8 years due to the closing of nearby mines and stripping operations.

Table 2.1 gives the population distribution within a 25 mile radius of the site. The population within 22.5° sectors of this area is listed in Table 2.2.

The predominant wind directions at the site are from the west-northwest and south-southeast. From a population distribution standpoint these are favorable, since they are not directed at the major population centers of the region nor into areas of above average population density.

2.4.1 Data Available

Meteorological data recorded at the facility site show its weather conditions to be quite similar to those at the Philipsburg airport, 27 miles southeast of the site, for which complete meteorological records have been kept. The information reported here is taken from observations at the airport, although observations are now being recorded at the site.

2.4.2 Wind Flow

Hourly wind observations for an eight-year period were studied in detail. Table 2.3 presents the annual frequency of wind speeds for various times and weather conditions; Figure 2.4 and Table 2.4 show the annual frequency due to time of day, weather condition and season of the year. The winds are predominantly from north-northwest to west-southwest and occur 30 to 40% of the the time. About 20% of the winds are from the sector from east-southeast to south.

Wind speeds during the daylight hours vary from a maximum average of 12.4 mph (spring) to 8.2 mph (summer). Night time speeds are somewhat lower, with a highest average speed of 10.1 mph (winter) and a lowest speed of 4.2 mph (summer). The maximum number of calms occur during the summer (night) when, 39% of the time, the wind is less than 1 mph. Maximum wind speeds are generally from the west with a maximum speed of 50 mph and a peak instantaneous gust of 60 mph recorded. Unrecorded

TABLE 2.3

gusts may attain 80 to 90 mph. It is noted that the most frequent winds are between 4 and 12 mph (50%) with the second frequency preference in the 13 to 24 mph category. Five tornadoes have been reported in the surrounding five counties in a 35-year period. The winds aloft have the same general pattern as the surface winds, except that they increase in velocity with altitude.

2.4.3 Precipitation

The average annual precipitation at the site is estimated to be between 40 and 50 inches per year. Maximum precipitation occurs in May through July, and the minimum precipitation occurs in November and December. The range of average precipitation is from 2.5 to 4.5 inches per month. Table 2.5 shows the average number of days of precipitation. Because of the frequency of storms, precipitation is quite variable. Storms occur throughout the year, with heavy rainfall from thunderstorms during the spring and summer months. Maximum precipitation varies from 1.38 inches, registered over a one-hour period, to 4.68 inches, recorded in a 48 hour period.

Snowfall is estimated to be an average total of 40 inches per year. Heavy snowfalls are not uncommon (10 inches in a single storm). The maximum snowfall recorded was 20.0 inches over a 24 hour period.

2.4.4 Atmospheric Stability

The vertical temperature distribution at or

Range of Precipitation Occurrences

≥0.10	From 72/year to 113/year
≥0.50	24/year to 38 year
≥1.00	3/year to 15/year

near the site has not been measured. Extrapolation has been made from other locations having similar weather conditions. Observations indicate that inversion conditions exist about one-third of the time, chiefly at night. Variations are expected in the duration of inversions due to the site topography where inversions in the air drainage of the radial gorges will be more prolonged than those on the plateau above. However, good dispersion is expected during the daylight hours, and inversions would be of short duration.

2.4.5 Temperature

The average monthly temperature ranges from 65°F in July to 22°F in January, with an annual average temperature of 44°F. Below-freezing temperatures occur many days per year.

2.4.6 Summary

Qualitative estimates of the meteorological pattern can be made from the Philipsburg Airport data and from regional characteristics which are relatively uniform. Diffusion characteristics can be deduced from the local topography and subsequent air drainage into the surrounding gorges.

2.5 Geology

2.5.1 Stratigraphy

Table 2.6 shows the stratigraphic section in the site area. Outcrops in the area are meager and incomplete logs of drill holes must serve as the basis for evaluation.

TABLE 2.6

Generalized Section of Geology at
Quehanna, Karthaus, Pennsylvania

Age	Formation	Thickness(ft)	Description	Water-Bearing Properties
Pennsylvanian	Pottsville	200 ±	Consists of massive coarse-grained gray-to-white sandstones with pebbles as large as hazelnuts. Caps hilltops. Probably represents the Olean member of formation.	Sandstones productive where found below drainage level, generally yield small to moderate supplies elsewhere.
Mississippian	Mauch Chunk shale	50 ±	Red and green argillaceous shale with some sandstone. Not generally exposed, indicated by terrace developed between Pottsville conglomeratic cliffs above and steep Knapp slopes below.	Not a water-bearing horizon, probably forms impervious strata retarding downward percolation of water.
Mississippian or Devonian	Knapp (Pocono)	600 ±	Succession of alternating olive-gray, gritty, micaceous sandstones gray-green argillaceous shales. Some red beds occur near bottom of formation.	Productive consolidated rock where encountered below drainage level.

However, due to the lack of tectonic disturbances in the area, lateral correlation from existing data is possible. The lower portion of the Pottsville formation caps the area. It consists of sandstones, with the lowest sandstone member as the predominant aquifer. This is underlain by the Mauch Chunk shale which is an impervious layer about 50 feet thick. Beneath it is the Pocono formation of interbedded sandstones and shales which form the steep slopes of the gorges.

2.5.2 Structure

In the site area the beds are generally horizontal and demonstrate the lack of structural disturbance in the area. In the northern portion of the site area, there is field evidence of gentle folding. Faults, joints and fractures are probably not abundant at the site, and the area is considered to be stable.

2.6 Hydrology

2.6.1 Subsurface Hydrology

As stated previously, the predominant aquifer in the area is contained at the base of the Pottsville, though it is not very productive. Since the Pottsville forms the surface exposure, it collects water and transmits it downward to a saturated sandstone member 40 feet thick near the interformational contact with the impervious Mauch Chunk shale. Secondary recharge is provided by streams cutting the Pottsville, and

discharge occurs at springs at the interformational contact. The top of Mauch Chunk is less than 1900 feet elevation and is presumed to be less than 100 feet, vertically, from the laboratory.

Water for the facility is obtained from a dam on Meeker Run. The dam is located upstream from the facility approximately 1100 feet down the mountain and is capable of releasing 120 gpm.

Downward transmission of contaminants released to the Pottsville formation is prevented by the underlying impervious Mauch Chunk shale. Lateral transmission within the Pottsville aquifer would be of a somewhat limited nature and would not pose a significant subsurface contamination problem in the light of the large exclusion area surrounding the laboratory. In fact, the movement of soluble contaminants within the Pottsville would be measured in the terms of feet per year. (Reference 2.4).

2.6.2 Surface Hydrology

Surface drainage from the site exclusion area is from four major radial stream systems; Mix Run (north), Wykoff Run (northeast), Upper Three Run (southeast), and Mosquito Creek (south). The former two streams drain into Sinnemahoning Creek, which flows into the west branch of the Susquehanna River; the later two drain directly into the river.

Of prime interest is Mosquito Creek, which drains the laboratory area as shown in Figure 2.5. Surface water in this area flows successively into Reactor Run, Meeker Run, Mosquito Creek and ultimately into the west branch of the Susquehanna. The river has a rather large average flow rate at Karthaus (maximum, 50,900 cfs; average, 2463 cfs; minimum 109 cfs). This branch of the Susquehanna is not used for public water supply because of its acidity (p H=3, Reference 2.4).

There are two reservoirs within the exclusion area, both of which are removed from the laboratory by several miles, and away from the runoff of Meeker Run.

2.7 Seismology

A total of six recorded earthquakes have had their epicenters in Pennsylvania, with some of the anadian and New York state earthquakes being felt there. Of the six epicenters cited, none was in the site region, and all were in Eastern Pennsylvania, involving low-intensity shock (maximum 6 to 7 Rossi-Forel Scale). It is consluded that, due to their low frequency and intensity, the foundation material, of the facility and its massive structure, earthquakes do not present a significant problem (Reference 2.5).

CHAPTER 3

PROCESS DESCRIPTION FOR STRONTIUM-90

3.1 General Description

3.1.1 Summary

The Quehanna Radioisotopes Pilot Plant processes strontium-90 to encapsulated sources suitable for a variety of uses. In this chapter the Quehanna process and planned variations used in production of strontium-90 fuel forms are described. In all variations of the process, a precipitate is formed from a $Sr(NO_3)_2$ solution by addition of inorganic nonflammable reagents. The precipitate is filtered and dried; the resulting powder is loaded and densified; the fuel container is sealed and decontaminated; measurements are made as desired and the final fuel container is loaded into a generator, cask or storage facility.

3.1.2 Possession and Process Limits

The Quehanna Radioisotope Pilot Plant is authorized to have in its possession a maximum of 6,000,000 curies of strontium-90. Radioactive contaminents in association with the 6,000,000 curies of strontium-90 will not exceed:

Strontium-89	1,800,000 curies
Cerium-144	30,000 curies
Other gross fission products	30,000 curies

The ratio of contaminents to Sr-90 will not be changed by processing.

Further limitations are established for maximum quantities of strontium-90 within the facility. These are:

1. Feed solution in HAPO shipping cask - 500,000 curies
2. Feed material stored in T-31 - 750,000 curies
3. Material in process, i.e., withdrawn from T-31, but not processed to final fuel form. (A final fuel form is a sintered pellet or fully processed fuel, densely packed into a fuel container by pressure or heat. A final fuel form does not consist of loosely packed fuel in a container.) - 50,000 curies
4. Material stored in final fuel form in chamber 4A, but not necessarily with the final seal made on the fuel container. - 150,000 curies
5. Total in chamber 4A - 150,000 curies
6. Sealed in metal containers and stored in chamber 4B - 100,000 curies
7. Total in process box - 250,000 curies
8. Sealed material in Cell 5 storage - 1,000,000 curies
9. Doubly-sealed material in pool storage - 5,000,000 curies

10. Waste; packaged in not more than 500 containers and awaiting removal - 22,000 curies

3.2 Feed Material Handling

3.2.1 Receipt of Shipping Cask

The AEC furnishes radioactive feed material to the Radioisotope Pilot Plant at Quehanna, Pennsylvania. Strontium-90, in the form of $SrCO_3$, is shipped in casks designed and fabricated by Hanford Atomic Products Operation of General Electric Company. This feed material, prepared from gross fission products, may contain, in addition to the strontium-90, activity due to strontium-89, cerium-144, and other fission products. There may also be non-radioactive strontium, barium and calcium compounds.

Each cask, loaded at the Hanford Works, is shipped from Richland, Washington, by rail and by motor truck to Quehanna. Upon arrival at the building containing the hot cells, the cask is removed from the truck by a crane and placed on a pallet truck; it is then moved into an airlock which provides access to the hot cell service area.

The cask and its content are under the continuing surveillance of the Health Physics group from its arrival until it leaves the site after being emptied. This surveillance includes appropriate surveys at each step in the process and any indicated corrective action required for the protection of personnel

and the area from radiation and contamination. (See Chapter 10 for details).

3.2.2 Preparation of Cask for Removal of Feed Material

The cask is moved from the airlock, through the service area and into the isolation room of Cell 4. The exterior of the cask is usually covered with heavy-duty aluminum foil at this point, both to guard against possible contamination of the cask during subsequent operations, and to lower the heat transfer rate of the cask cooling fins. The decreased heat loss is desirable for the leak check of the cask cooling coil performed prior to cask unloading. The protective blanks are removed from the cask cooling coil and the heater well and the outer well cover is removed from the depression on top of the cask which contains the triply-sealed process line blanks; the cover of the triply-sealed cask vent valve connection is also removed. The following connections, which may vary with the particular cask as indicated, are made:

(1) A line is connected to the cask cooling coil inlet to permit introduction of either high velocity (up to 60 cfm) air, or water from ambient temperature to 180°F.

(2) A line is connected to the cask cooling coil outlet. This line is provided with valves which permit the air from the coils to be exhausted through the filtered cell

air exhaust system and water from the coils to be returned to the closed cycle water system.

(3) A thermocouple is inserted through a well on the cask to indicate the cask inner temperature.

(4) A special rod-type electric heater is inserted in the heater well on the top of the cask. The heater is connected to an electrical circuit through controlling and monitoring devices such as a variable output transformer or volt-ampere meters.

(5) In cases where the cask is fitted with a gas pressure transmitter over the internal annulus containing the heat transfer medium, air lines are connected to a booster valve and indicator or other appropriate readout instrument. In cases where a direct reading pressure gauge is provided, the gauge is read by the use of a closed circuit television system.

The next step is a leak test of the cask cooling coils. The test is performed in accordance with standard instructions from Hanford and consists of the following steps:

(1) The cask temperature is increased until

the heat transfer medium is molten. The electrical heater is normally used for this step.

(2) High pressure air (about 70 psig) is introduced to the cask cooling coil with the discharge line closed.

(3) The pressure on the cask gauge or transmitter is observed for thirty minutes. Since the gauge lead on the cask penetrates to the argon filled volume in the same cavity with the molten alloy, any increase in pressure on the gauge would indicate a leak in the cooling coil.

(4a) Should no leak in the coil be indicated, the cask is cooled according to a standard procedure to minimize internal stress on the cask and coils as the alloy solidifies and the cask is readied for unloading. The cask may be cooled by simply removing the electrical heater and passing high velocity cool air through the coil or, after partial cooling has been achieved, controlled temperature water may be used to increase the heat loss.

(4b) Should it be determined that a leak exists

in the coil, the electrical heater would be turned off and steps would be taken to cool the cask short of introducing water to the coil. The AEC would be notified and no further action would be taken to unload the cask pending instructions from the AEC.

The leak check may be performed either directly or remotely. It is usually performed remotely because complete instrumentation is provided on the cell face for the operation.

Upon completion of the leak test, a ventilated cupola is sealed to the top of the cask. This cupola is similar to a standard glovebox in concept in that it has glove ports, an absolute type filter on both the inlet and exhaust air lines and a transfer port as well as provisions for sealing the process line penetrations. The four process lines are inserted into the cupola and the insertion port is sealed, after which the following operations are performed:

(1) The two secondary covers are removed from the cask vent valve, the vent line is attached, and the vent valve is opened to relieve any pressure in the container.

(2) The second of the three protective covers are removed from each of the three cask process line blanked connections which are located in a well.

(3) Each of the cask process line blank fittings are removed and the connection to its respective line is made in such a manner that only one line is open to the cupola at one time. The connections are not necessarily made in the order given below.

(a) The solvent feed line is attached to the cask connection marked FILTRATE OUT. This method of adding the solvent permits a back-washing action of the filter and a subsequent fast release of the filter cake to the bottom of the cask container.

(b) One branch of the line leading to the feed storage tank is connected to the cask fitting marked SLURRY IN. The SLURRY IN line penetrates only to the top of the product container, so when fitted with a separate valve, this connection permits release of the gas buildup encountered during dissolution of cask content without forcing the dissolving liquid out of the bottom of the cask.

(c) The second branch of the line mentioned in (b) above, is also fitted with individual valving and is connected to the cask fitting marked SOLVENT IN. This line penetrates to the bottom of the cask container and is used to transfer the dissolved product to the feed storage tank.

3.2.3 Removal of Feed Material From Shipping Cask

The feed material is received as a solid strontium carbonate cake loaded on a filter screen in the product container portion of the shipping cask. Nitric acid of various concentrations is used to loosen the cake from the screen and to dissolve it for transfer to the feed storage tank as soluble strontium nitrate.

Each dissolution is calculated from the analysis furnished by HAPO. This analysis gives the curies of strontium-90, the ratio of total strontium to strontium-90, and the amount of inert impurities as a ratio to total strontium as well as the radioactive impurities as a ratio to the curies of strontium-90. The quantity of nitric acid required to completely dissolve the contents of the cask and leave the resulting feed solution from 0.4 to 0.6 molar in free acid is then added. The total liquid volume is calculated to make the radioactive concentration of the feed solution from 2.0 to 3.0 curies per milliliter with

respect to strontium-90. The actual dissolution of the cake and transfer of the resulting solution is carried out as follows:

(1) The fittings between the cask and the storage tank are leak checked by pulling a vacuum on the system, closing the vacuum valve, and observing the leak-down rate. No acid is added to the system until a satisfactory vacuum can be maintained.

(2) The valve in the line connected to the cask SLURRY IN fitting is opened to permit release of carbon dioxide, a slight vacuum is placed on both the cask and the feed storage tank through the storage tank (T-31), and a few (5 to 10) liters of dilute (0.5 to 1.0 molar) nitric acid are added through the solvent feed line. This first addition is made at a carefully controlled rate which does not exceed 100 ml per minute in order to prevent an overly vigorous reaction and to permit the vacuum to be maintained in the system. Added precautions, such as a check valve in the solvent feed line to prevent release of carbon dioxide through that system are included. As noted previously the feed storage tank

(T-31) is maintained at a negative pressure during dissolution. The vacuum system has an 8.4-cfm pump and a surge volume in excess of 200 liters. The acid is added at a rate that does not exceed 0.3 moler per minute. If the carbon dioxide is released at the same rate the evolution does not exceed 6.72 liters/minute, STP. The volume produced is negligible in comparison to the capacity of the vacuum system. No difficulty has been encountered in maintaining a negative pressure in the cask.

(3) The material added in step (2) is allowed to digest until no further reaction is apparent, after which small volumes of more concentrated (up to 4 molar) nitric acid are added and allowed to digest. The technique described in steps (2) and (3) prevents an overly vigorous reaction rate with attendant loss of control while permitting one to obtain a relative high nitrate ion concentration in the final solution.

(4) When the cask is filled with liquid and

digestion is complete, the valve on the SLURRY IN line is closed, the valve on the SOLVENT IN line is opened, and the solution is transferred to the feed storage tank by vacuum.

(5) Steps (2), (3) and (4) are repeated with variations in acid concentration until all the acid has been added and a final water wash of the cask has been performed.

(6) The contents of the feed storage tank are air sparged and a sample is taken and radioassayed. This assay is compared to the Hanford analysis to determine the amount of activity remaining in the cask.

The cask is dried by the use of heat and vacuum, the lines disconnected, the seals replaced, the cask decontaminated, placed in its outer shipping container or bumper, and returned to the railhead for shipment to Hanford.

3.3 Processing to Fuel Form

3.3.1 Metering and Precipitation of Feed Solution

The solution in the feed storage tank (T-31) is mixed by air sparging prior to transferring each batch of solution; this is accomplished by opening the air sparge valve connected to the vent header and drawing a slight vacuum on the tank to bubble air through the solution for 15 to 30 minutes. After sparging, a sample is taken to check the free acid content of the solution and to insure that no evaporation with accompanying concentration of the solution has occurred. The remainder of the required analyses, such as total cation concentration and strontium-89/strontium-90 ratio are run at the start of processing each new cask as a check on the Hanford furnished analysis. Experience to date has shown the Hanford analysis to be accurate in every case within the limits of experimental error.

The process feed batch is transferred from the feed storage tank (T-31) to the precipitation tank (T-33) via a fine metering tank (T-32). In addition to the Foxboro liquid level indicator, accurate to plus or minus 0.5 percent, this small tank is equipped with three calibrated stand pipes which deliver 1, 2 or 3 liters. All excess solution is returned to the feed storage tank and, if for any reason it is not desired to dump the batch to the precipitator, all feed may be returned to the storage tank.

The acidic strontium nitrate solution is adjusted to the desired pH with a sodium hydroxide solution.

The temperature of the precipitator may be varied from about 55°F to nearly 180°F by circulating water at a controlled temperature through the external coils of T-33. All liquid reagents are added to the precipitator from a metering tank in the operations area by means of a diaphragm pump through appropriate block valves, check valves and a siphon break. Solid, reagents, such as TiO_2, are weighed in the laboratory into small plastic bottles, passed into the process box and dumped into the top of the precipitator through a funnel which may be sealed when a vacuum on the precipitator vessel is required. See Section 3.6 for reagents and quantities used.

The precipitating reagents are added to the neutralized or slightly basic strontium nitrate solution in amounts stoichiometric to the total cation concentration. The mixture is stirred, either by an air driven mechanical stirrer or by pressure air sparging at approximately three liters per minute and 5 psig pressure. The air supply for sparging is located in the isolation room of Cell 4. It is controlled by check valves and double pressure reducers. The sparging is turned on and off from outside the isolation room. A bleed line is installed adjacent to the bottle; in the event the line becomes clogged the pressure can be released to the cell. The optimum flow rate for sparging varies slightly with batch size.

Upon completion of the digestion period, the precipitator may be brought to ambient temperature and cold water added to speed settling of the precipitate. After allowing time for settling, the precipitate is drawn over to an alundum filter-crucible in filter housing T-34 and the filtrate collected in the filtrate storage tank (T-25) by applying vacuum to T-35 and opening the valve connecting T-33 through T-34 to T-35. T-33 and the precipitate are washed with water, as required, by adding water to T-33 and drawing it by vacuum into T-35.

The filtrate and washings, stored in T-35, are assayed. Should an activity of more than 3 curies/liter be present as would occur if insufficient sodium hydroxide or precipitating reagent were added to the batch or if the T-34 filter had been defective or the seals had been imperfect, the washed precipitate would be removed from T-34 in its crucible, the crucible would be replaced with an empty one, and the filtrate and wash from T-35 would be recycled through T-33 and T-34 to T-35 after any required reagents had been added. The T-35 solution would be resampled and, if the strontium content were low enough, the solution would be vacuum-transferred to the waste storage tank, T-20. The T-35 solution is normally transferred to T-20 immediately after assay.

3.3.2 Calcination, Blending and Compaction

The alundum crucible containing the precipitate is removed from the stainless steel filter holder (T-34) by swinging back the top and lifting out the crucible with manipulators using a special handling tool. The contents of the crucible are examined visually and the crucible and contents are placed in the furnace for the drying and/or calcination step.

3.3.2.1 Process Furnace

The furnace used for the drying step is a versatile unit capable of sustained operation at temperatures as high as 1500°C; it is also used for subsequent sintering steps. The furnace proper is heated by three sets of four "glo-bar" resistance elements, with each set being individually adjustable for output from the control panel in the operations area. The entire furnace is powered and automatically controlled through a saturable reactor which receives its signal from one of six replaceable thermocouples in the furnace; the furnace cycle can be varied within a wide range by use of precision cut cams. The in-cell portion of the assembly is easily removable from its water-cooled well in the process box for replacement of heating elements and thermocouples.

3.3.2.2 Drying and Calcination

The purpose of this operation is to dry the filtrate and remove CO_2 without raising the temperature high enough to sinter the product. The furnace is closed, but not sealed air tight. The temperature is taken to 250 to 300°C and held for sufficient time to insure removal of free water vapor. After this drying is complete, the temperature in the furnace is increased to 600 - 970°C depending on the batch size and the product desired. Maximum temperature is maintained for a predetermined period. In one case, the reaction rate of the strontium carbonate - TiO_2 mixture is temperature dependent above its initiation temperature and since considerable self-heating occurs from the strontium-90 content a relatively low temperature is maintained for several hours to permit conversion to strontium titanate without sintering the central portion of the cake. In the other case the removal of occluded water is a relatively slow process.

3.3.2.3 Blending

It is necessary to break up lumps and reduce the particle size of the dried and calcined cake prior to final fuel forming to obtain consistently high density material. At the present time, a Waring-type blender is used for this operation, but other equipment such as a "y" tube blender and a small, enclosed hammer mill will probably be tested and used.

3.3.2.4 Powder Densifying

Strontium titanate powder has traditionally been pressed into "green" pellets by standard powder metallurgical techniques, using a die of the desired dimensions, loading the die with the desired mass of powder and pressing with a hydraulic press. The pellet is then sintered at high temperature to cause it to shrink with an accompanying increase in density. The Quehanna Pilot Plant has retained this capability, which requires a pressure of only about 5 tons per square inch on the pellet area, and at the same time has built-in versatility to permit more efficient compaction. When sintered pellets are loaded into capsules there are always void spaces which decrease the power density. Work done by Martin Nuclear Division indicates that good density material without voids may be obtained by "step pressing," particularly when strontium compounds other than the titanate are made. In this process, a fuel container is placed in a large die and a small volume of powder is added and pressed at 40 to 50 tsi. The process is repeated until the container is full or until the desired thermal output is obtained. A 250-ton press with a 12-inch ram is employed in the process box. The hydraulic unit is located in the operations area and connected to the ram by high pressure tubing through the cell wall. When step pressing is employed, sintering is omitted.

3.3.2.5 Sintering

Green titanate pellets are transferred onto zirconia covered setter plates, the plates are loaded into the furnace in as many as three trays at different elevations and a programmed sintering cycle is initiated. The maximum sintering temperature is about 1450°C and a complete cycle requires approximately 20 hours. Inert gas services are provided in the furnace. Upon removal from the furnace, the fuel pellet is checked for physical characteristics and thermal output.

3.3.3 Interim Fuel Storage

Shielded storage units are provided in both chambers of the process box to permit storage of either exposed or sealed fuel and containers as desired during processing. If the pellet form of material is required, batches of pellets would be stored in special open liners until the correct number and type of pellets were available to make a final capsule loading. If step-press loading is employed, a container or containers will also be stored temporarily until loading is completed. Open storage will be used only in the shielded storage chamber accessible to the A side of the process box. Shielded storage is also provided on the B side of the process box for temporary storage of sealed containers. The shielded storage chambers are so designed that air will circulate through the interior and the fuel will thus be cooled by convection currents.

3.3.4 Fuel Container Welding

Both final fuel containers and containers to be used for long-term storage are welded shut. The welding is performed by use of an Heliarc power supply placed near the face of the cell and a welded tip and jig within the cell. Materials to be welded will be chosen from among 300 series stainless steel, Hastelloy C, Haynes 25 and tantalum. Techniques and apparatus for each welding requirement are tested and approved by Quality Control prior to utilization. Such materials as Hastelloy C and 300 series of steel have been remotely welded successfully with penetrations from 0.015 inch for light stainless steel liners to 0.090 inch on Hastelloy C with this apparatus.

Prior to removing any welded fuel container from the process box, a mass spectrometer leak check is performed. The existing system can detect leaks as small as 10^{-8} standard cc's of helium/second; the acceptable maximum leak rate for a welded fuel container is 5×10^{-6} standard cc's of helium/second.

3.3.5 Fuel Container Decontamination

Decontamination of each sealed fuel container is performed in several steps. The first step is in the A side of the process box accomplished by the use of an immersion bath.

Each immersion tank is fitted with ultrasonic transducers to assist in the cleaning. After the preliminary decontamination, the container is moved to the B side of the process box and immersed in additional ultrasonic cleaning tanks. The immersion may be interspaced with scrubbing and/or the use of special reagents as required. Swipe samples are taken, removed from the box and counted to determine when the fuel container is sufficiently cleaned for removal from the B section of the process box. The decontaminated container is transferred to Cell 5 for calorimetry and storage in the shielded capsule storage container. From there, if long-term storage will be required, it is sealed in a secondary stainless steel container, welded, leak checked and transferred to the gamma pool after the required waiting period.

3.4 On-Site Storage

3.4.1 Cell 5 Storage

Storage in this cell is described in Paragraph 9.1.3.3.

3.4.2 Transfer from Cell 5 to Pool Storage

The cask (see Paragraph 9.1.2.3) containing the doubly sealed and leak-tested capsules is removed from Cell 5 in either of two ways.

The service area crane is used to lift the cask out the top of Cell 5 through the opening left by removing the concrete roof plugs. The crane then moves on an unobstructed direct path to the pool. The cask is moved over the pool edge above the specified section of pool in which no capsules are stored. This prevents the possibility of the cask being accidently dropped on a capsule. The cask is lowered into the pool. A special tool is used to remove the capsules from the cask. The cask is removed from the pool, drained and decontaminated, if necessary, for further use.

The other method of transfer is performed by using a dolly to remove the cask from Cell 5. The dolly is moved across the smooth, unobstructed floor to the edge of the pool. The service area crane is then used to place the cask in the pool as in the other method.

3.5 Final Loading Operations

Prior to loading into a generator or shipping cask the decontaminated fuel capsules are accumulated in the Cell 5 shielded storage container. Calorimetry is repeated if desired, all capsules returned to the Cell 5 shielded storage container and the generator or cask is moved into Cell 5. The loading operation entails either the placement of one or more fuel capsules in the shielded generator block, addition of shielding to the generator, and a final checkout of the generator

internal atmosphere and electrical output prior to shipment to the Baltimore site for further testing, or, loading one or more fuel capsules into a shipping cask, attaching the cover and final checking of the cask before release for shipment to its destination.

3.6 Reagents

This section is classified and will be transmitted as a separate submittal.

CHAPTER 4

ADMINISTRATIVE CONTROL

The function of the administration of the Radioisotopes Production Pilot Plant is the economical processing and encapsulation of radiostrontium for power production. Recognizing that the handling of multicurie quantities of strontium-90 presents safety problems unique in private industrial operations, the Martin Company has set up administrative controls designed to enable the plant operations to be carried on with the least possible hazard. (Refer to Figure 4.1)

4.1 Operations and Responsibilities

In order to achieve the necessary degree of administrative control, reliance is placed not only on defined procedures but also on properly trained and indoctrinated personnel. This concept of administrative control starts with the hot cell operator and his responsibilities, and works up in the line and staff organization through a series of overlapping responsibilities which provide necessary checks on the operations. This system may perhaps be explained most readily by a review of responsibilities.

4.1.1 Hot Cell Operator

The hot cell operator is responsible for carrying out the actual processing operations. The operations to be conducted during each shift are reviewed with the operator by

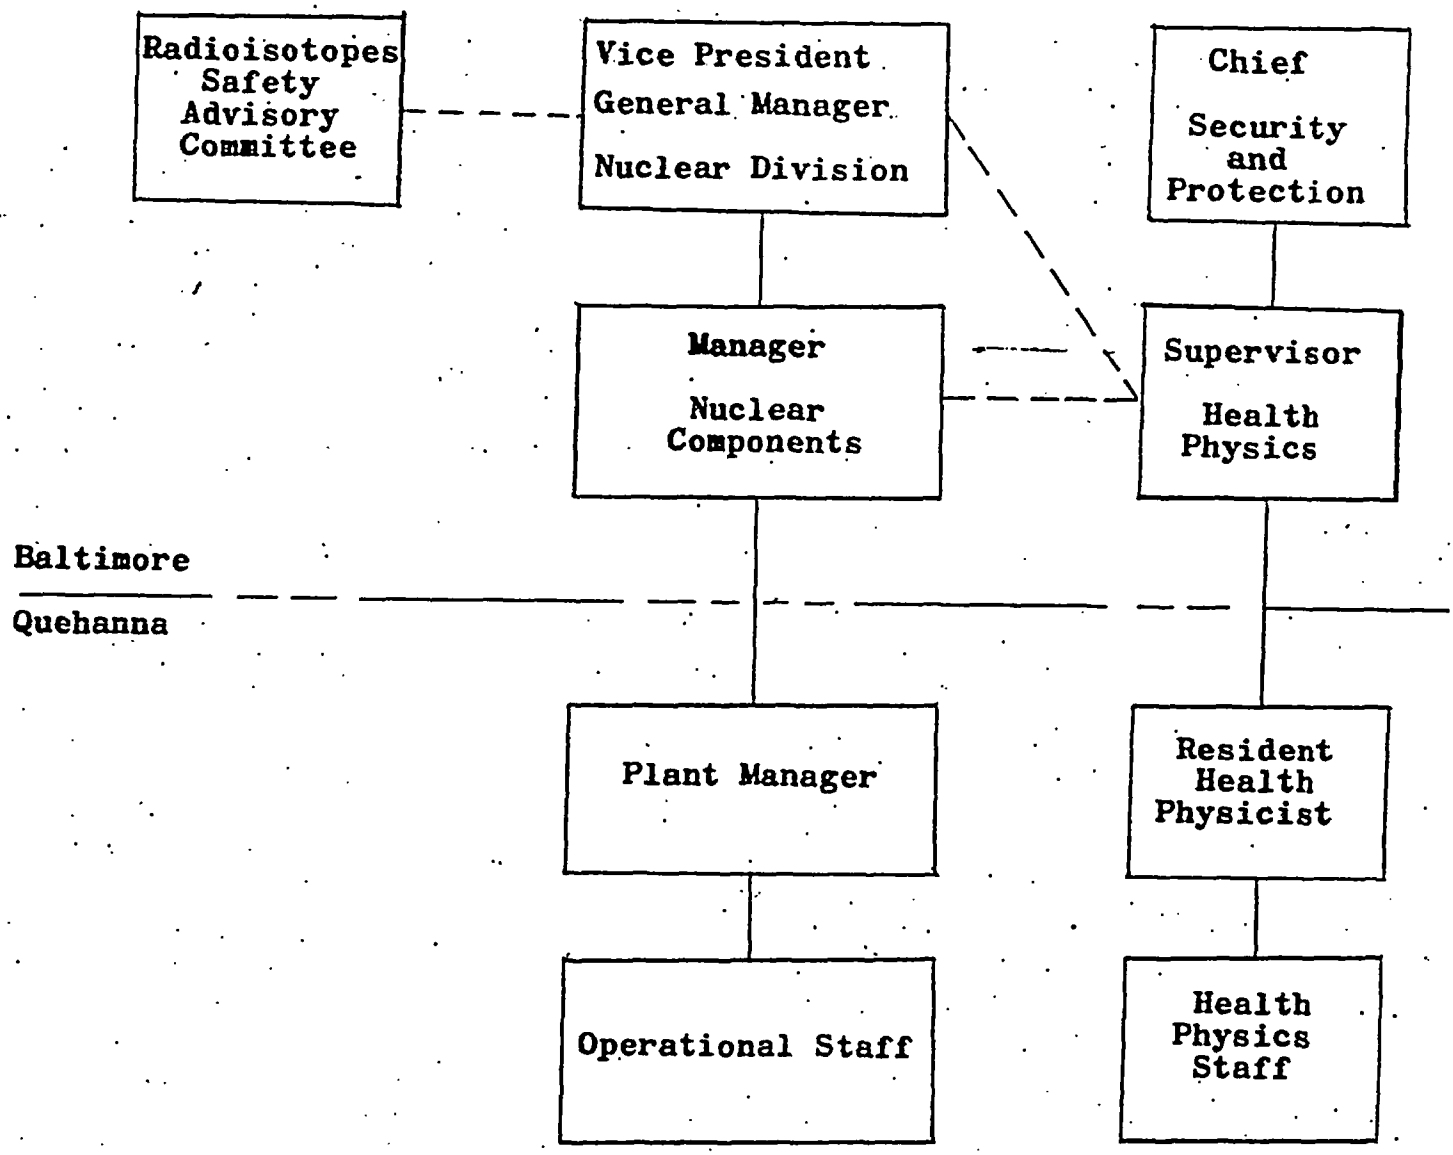

Figure 4.1 Organization Chart

the shift supervisor. Operations are carried out in accordance with previously defined and authorized procedures. The operator will have been trained not only in these specific procedures but also in the basic arts of health physics and radiochemistry with emphasis on proper actions in case of emergency. Apprentice operators will work along with experienced operators.

The operator will keep a running log of the tasks he performs, recording all pertinent data, e.g., volume of solutions transferred, temperatures of solutions, duration of operations, analytical results. Any evidence of unusual behavior in the process, process equipment or facility equipment will be recorded and brought immediately to the attention of the shift supervisor.

No deviations from the defined, normal operating procedures will be made by any operator unless authorized by his shift supervisor. Such deviations must be noted and emphasized in the log. The operations log is the basic record of all operations at the facility.

4.1.2 Shift Supervisor

The shift supervisor is responsible for conducting scheduled operations in accordance with the authorized procedures and instructions, and for directing and assisting his assigned operators in their work. He will receive written and oral instructions from the Supervisor of Process and Quality

Control defining the operations to be performed on his shift. Third shift supervisor will usually receive only written instructions, with oral instructions transmitted to the second shift supervisor. In order to cope with minor deviations in the process, the shift supervisor will be authorized to improvise manipulative changes to correct the aberrations. He is encouraged to delineate facts and make recommendations, but he will not make any changes involving additions of chemicals or alterations in process conditions without review and approval by higher authority.

The activities of the shift will be summarized in the operations log by the shift supervisor. He will note the transfer of radioactive material from one location to another and from one form to another, unusual occurrences in process or facility, and unusual maintenance requirements. He will examine and initial his instruction log book and bring the next shift supervisor up to date on the facility status and production situation.

4.1.3 Process and Quality Control Supervisor

The Supervisor, Process and Quality Control, is responsible for planning production operations, improving operational techniques and maintaining the quality of product. He will make daily assignments of operating orders and check housekeeping through daily personal surveillance and review of

the shift operations log.

Through coordination with the Plant Manager, Process Chemist, Licensing Specialist, Process Equipment Engineer and resident Health Physicist, he will insure that all materials are available and requirements met for safe accomplishment of production schedules.

He will review suggestions for process or procedure changes and forward his recommendations to the Plant Manager. He may not authorize any substantive change in established operating procedures without higher approval.

The Supervisor of Process and Quality Control will submit a daily report to the Plant Manager summarizing the information in the operation log and will inlcude his personal observations and comments concerning the achievement of production schedules and the safety of the operations.

4.1.4 Manager, Radioisotope Pilot Plant Section (Plant Manager)

The Plant Manager is responsible for the safe and productive operation of the Quehanna facility. He will direct all operations, approve operating procedures and establish goals consistent with the license for the facility and any further restrictions he deems necessary. He will receive processing requests and funding from other areas of the Nuclear Division. He will coordinate and measure the activities within his section, and will request the support required from other sections through the Manager, Nuclear Components, so that

training, preparation and stockpiling will be achieved on time and in proper degree to meet established goals.

He shall stop, or prevent the start-up, of any operation at the Quehanna facility when, in his judgment, such operation would be in violation of the license, or otherwise be in contradiction to safe practice. He shall take similar action, regardless of his personal judgment, if so ordered by the Manager, Nuclear Components, or the Commission.

He will review the daily reports of the Supervisor, Process and Quality Control, the weekly reports of the resident Health Physicist and make frequent personal inspection of the facility and logs. From these and other data, he will submit a written report to the Manager, Nuclear Components, on a weekly basis, summarizing the status of the facility and the week's activities.

He is responsible for anticipating the need for amending or up-dating sections of the license and initiating action. In this regard, he will frequently compare the goals and long range plans for the facility with the license and current practice. From this analysis, he will take action within his section and request support from other sections as required to prepare other reports and data as ordered by the Manager, Nuclear Components.

4.1.5 Manager, Nuclear Components Department (Department Manager)

The Manager, Nuclear Components, is responsible for maintaining a satisfactory Radioisotope Pilot Plant facility, a competent operating staff of adequate size and for assuring safe operation of the facility in accordance with the license. He will review and retain for file in Baltimore the weekly summary reports by the Plant Manager, make personal inspections of the facility and logs at 4 to 6 week intervals, and take whatever other action he deems necessary to assure himself that the facility and operations are maintained in accordance with the license. He has the authority to order the cessation of any operation he deems unsafe. He will advise the General Manager of the Nuclear Division of the status at Quehanna on a weekly basis. He will provide, or take necessary action to provide, the required support activities for Quehanna. He will cooperate with the Radioisotope Safety Advisory Committee, providing reports and data requested and assisting the Committee in its investigations.

4.2 Administrative Checks

In addition to the control provided in the organization and mode of operation of the Nuclear Components Department, two independent parallel administrative checks have been established. These are the Nuclear Division Radioisotope

Safety Advisory Committee and the administrative participation of the Health Physics organization.

4.2.1 Health Physics

The organization and responsibilities of Health Physics are presented in Chapter 10. In addition to its conventional duties the Health Physics organization participates in the administrative control of the Radioisotopes Production Pilot Plant. As an ultimate check, the resident Health Physicist may stop any operation at the facility which he feels is being carried out in a manner contrary to safety regulations and constituting a definite hazard to the facility personnel and to the public.

4.2.2 Radioisotopes Safety Advisory Committee

The Radioisotopes Safety Advisory Committee has been constituted for the purpose of increasing assurance of the safe use and possession of radioisotopes within the Nuclear Division. It reviews the criteria that are generated by line organizations to ensure the safe operation of any activities utilizing radioisotopes. It carries out periodic surveillance of such operations. The chairman of the Committee reports directly to the General Manager and Vice-President of the Nuclear Division.

4.3 Fire Prevention and Control

The unusual nature of the plant operations with the potential hazard of radioisotopic contamination and nuclear radiation, and the isolated location of the Quehanna facility have caused considerations of fire prevention and control to be of particular concern. This leads to the requirement of frequent inspections and special training in fire fighting.

4.3.1 Inspections

Monthly inspections are made by the Quehanna Radioisotope Pilot Plant personnel accompanied by the representative of the Pennsylvania State University. Findings of these inspections are distributed to officials at Pennsylvania State University and the Plant Manager for action.

4.3.2 Training Program

All male personnel at the Quehanna site are trained in fire fighting. The training program is described in Chapter II, Summary of Emergency Control Measures.

4.4 Qualifications of Personnel

4.4.1 Operating Personnel

The following categories of personnel are actively engaged in the handling and/or control of radioactive materials at the pilot plant. The minimum acceptable qualifications for each category are:

4.4.1.1 Hot Cell Operator

4.4.1.1.1 Operator C (trainee)

High school education and at least 4 years experience of a general mechanical nature.

2 years of college--2 years of college may be substituted for the general experience and non-diploma technical courses may be substituted for experience in some cases.

Each employee must be of such character as to permit obtaining an AEC Q clearance.

4.4.1.1.2 Operator B (intermediate)

All qualifications listed above plus (1) successful completion of a radiation protection training course of at least 16 hours duration, (2) demonstrated competence in each mainpulative operation involved in processing, and (3) at least 18 months experience in handling radioactive materials.

4.4.1.1.3 Operator A (journeyman)

All qualifications listed above plus (1) at least 36 months experience in handling radioactive materials, (2) an understanding of each phase of all operations and a demonstrated ability to explain the operation to others, and (3) understanding and awareness of the radiation hazard in any operation with radioactive materials and a demonstrated record of safety.

4.4.1.2 Shift Supervisor

(1) all qualifications of an A operator, (2) demonstrated initiative and organizational ability, (3) at least 5 years experience in the nuclear field, of which at least 2 years must have been spent as an A operator or equivalent.

4.4.1.3 Supervisor, Production and Quality Control

Education--BS, Chemistry or Chemical Engineering. Directly applicable experience in the field may be substituted on the basis of 2 years experience for 1 year of college.

Experience--at least 8 years of high level radioactive chemical experience required, of which at least 3 years must have been in a supervisory capacity.

4.4.1.4 Manager, Quehanna Pilot Plant

Education--BS, Chemistry, Chemical Engineering or Nuclear Engineering.

Experience--8 years experience handling high level high specific activity radioactive materials. Advanced schooling in radiochemistry, nuclear engineering or radiation protection may be substituted on a year-for-year basis for up to 3 years experience. A minimum of 2 years supervisory experience in the nuclear field is required.

4.4.2 Health Physics Personnel

4.4.2.1 Resident Health Physicist

The following minimum requirements are necessary for the position of Resident Health Physicist:

Education: B.S. in Physics, Chemistry or equivalent.

Experience: Two (2) years experience in Health Physics administration and control procedures with particular emphasis being placed on personnel possessing high level hot cell experience.

4.4.2.2 Health Physics Technician

The following minimum requirements are necessary for the position of Health Physics Technician.

Education: High School graduate or equivalent plus specialized training in radiological protection, electronics, or laboratory techniques.

Experience: Six months experience in Health Physics or related work to become familiar with radiological monitoring and laboratory methods and procedures. In addition will require an apprenticeship period at the facility working along with experienced Health Physics Technicians. The length of on-the-job training will be governed by an individual's ability, experience and educational background.

4.5 Summary

In recapitulation, the Martin Company has set up an administrative system that provides safety in the handling of multi-kilocurie amounts of radioisotopes. This system is based upon the following elements:

4.5.1 A physical plant providing for control of radioactive material in normal and conceivable emergency circumstances.

4.5.2 Experienced personnel well-trained and indoctrinated in requirements for safe handling of radioisotopes.

4.5.3 A system of supervisory progression within the line group providing for overlapping responsibilities and checks upon the standard operating procedures.

4.5.4 A system of records and reports which provide complete awareness of the status of the facility and its contained radioactive materials at any time.

4.5.5 An independent staff function through Health Physics which provides a continuous check upon the operations of the line group and the safety of the facility.

4.5.6 A second independent staff function through the Radioisotopes Safety Advisory Committee which advises the General Manager in matters related to safe operation of facilities.

4.5.7 A special concern for indoctrination and good training in fire prevention and control.

CHAPTER 5

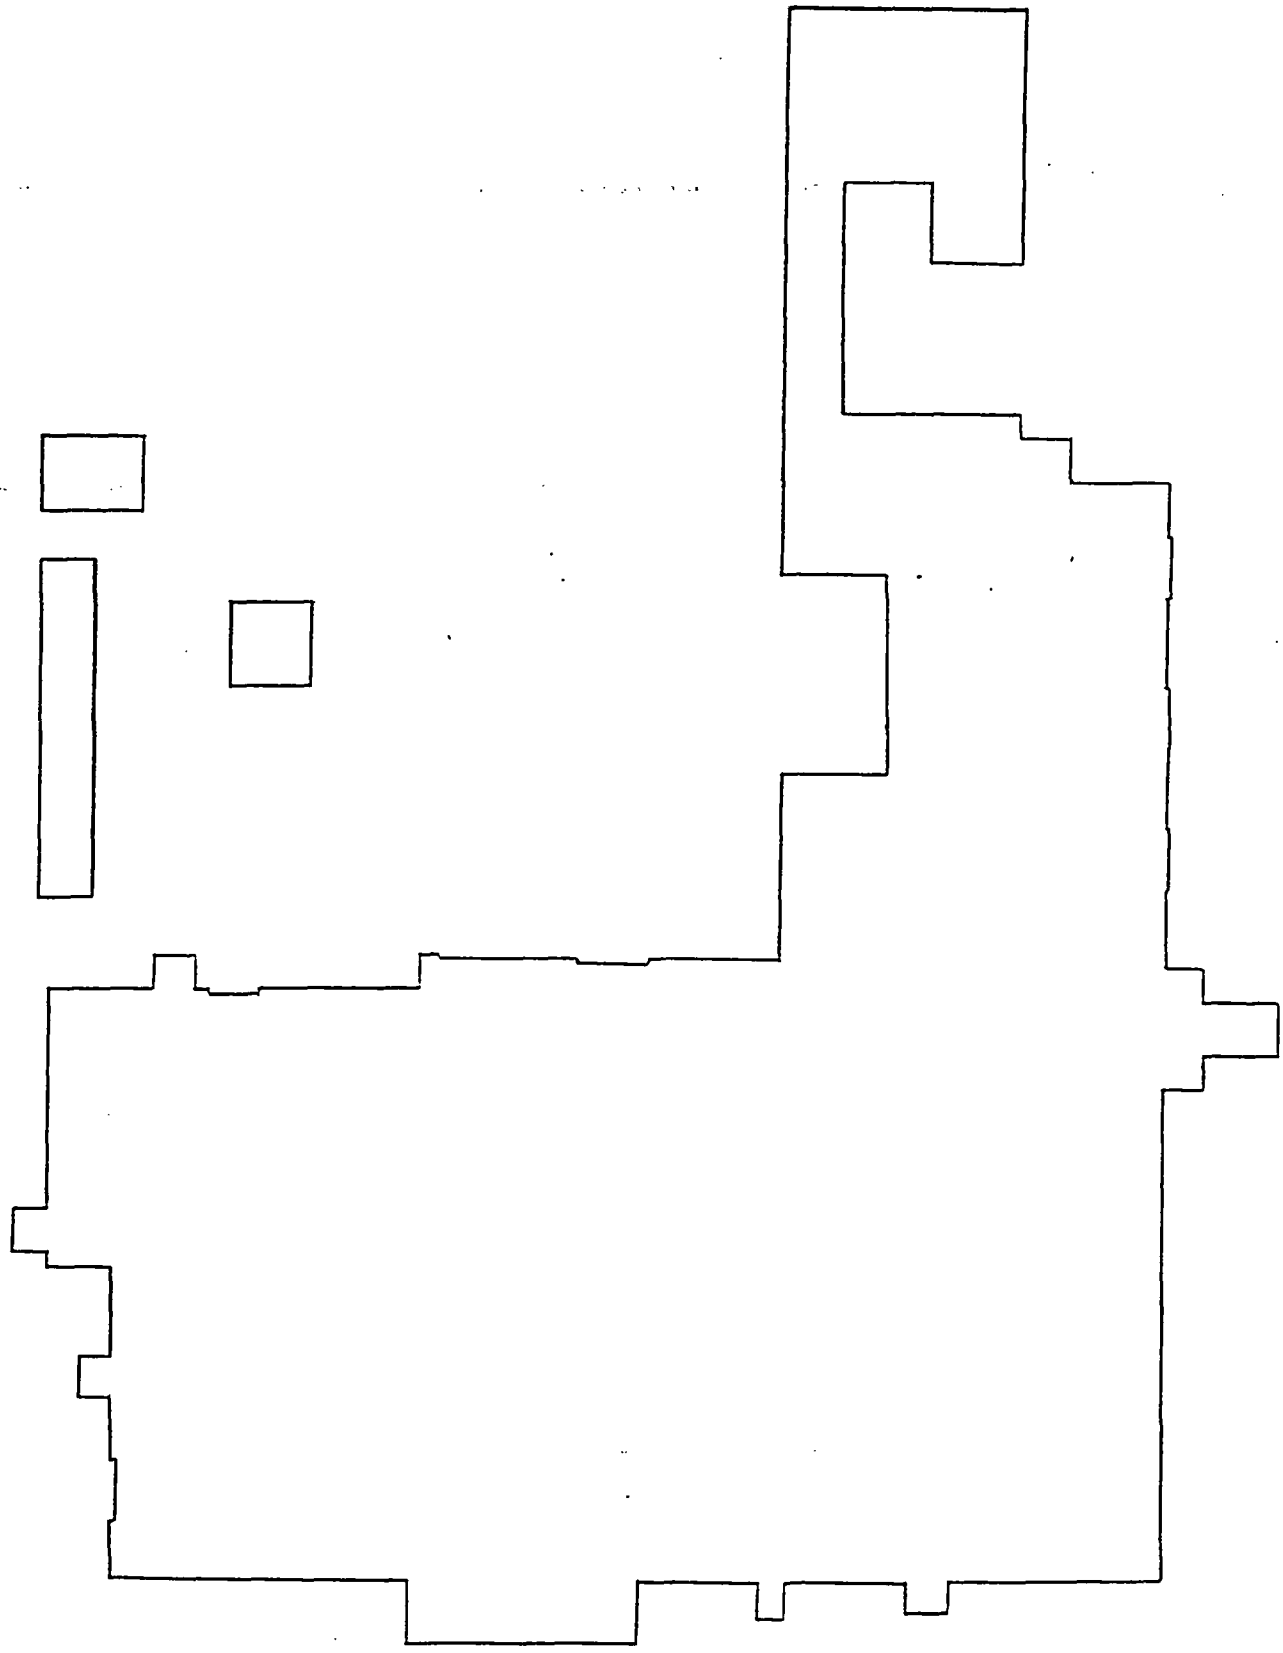
PLANT DESCRIPTION

5.1 Description and Arrangement

5.1.1 General

A view of the exterior of the facility building is shown in the frontispiece. The exterior, of simplified contemporary design, consists largely of insulated aluminum curtain walls applied to the steel frame. The two large bays housing the reactor and the hot cell service area are evident. The reactor area is isolated from the cell service area, except for a large truck door and a pedestrian door, both of which will normally be closed and locked. The general layout of the site (frontispiece) shows the relative position of the main plant, radioactive waste treatment plant, storage buildings, and underground holdup and storage tanks.

The 24,700 square foot reactor and hot lab building is basically a one-story structure. The main floor plan and the basement floor plan are shown in Figures 5.1 and 5.2. The Martin Radioisotopes Pilot Plant includes all areas encompassed by the heavy line on the vellum overlay. The plant has been designed to provide as positive separation as possible between radioactively contaminated and radioactively clean areas. Those areas which are maintained free of contamination include



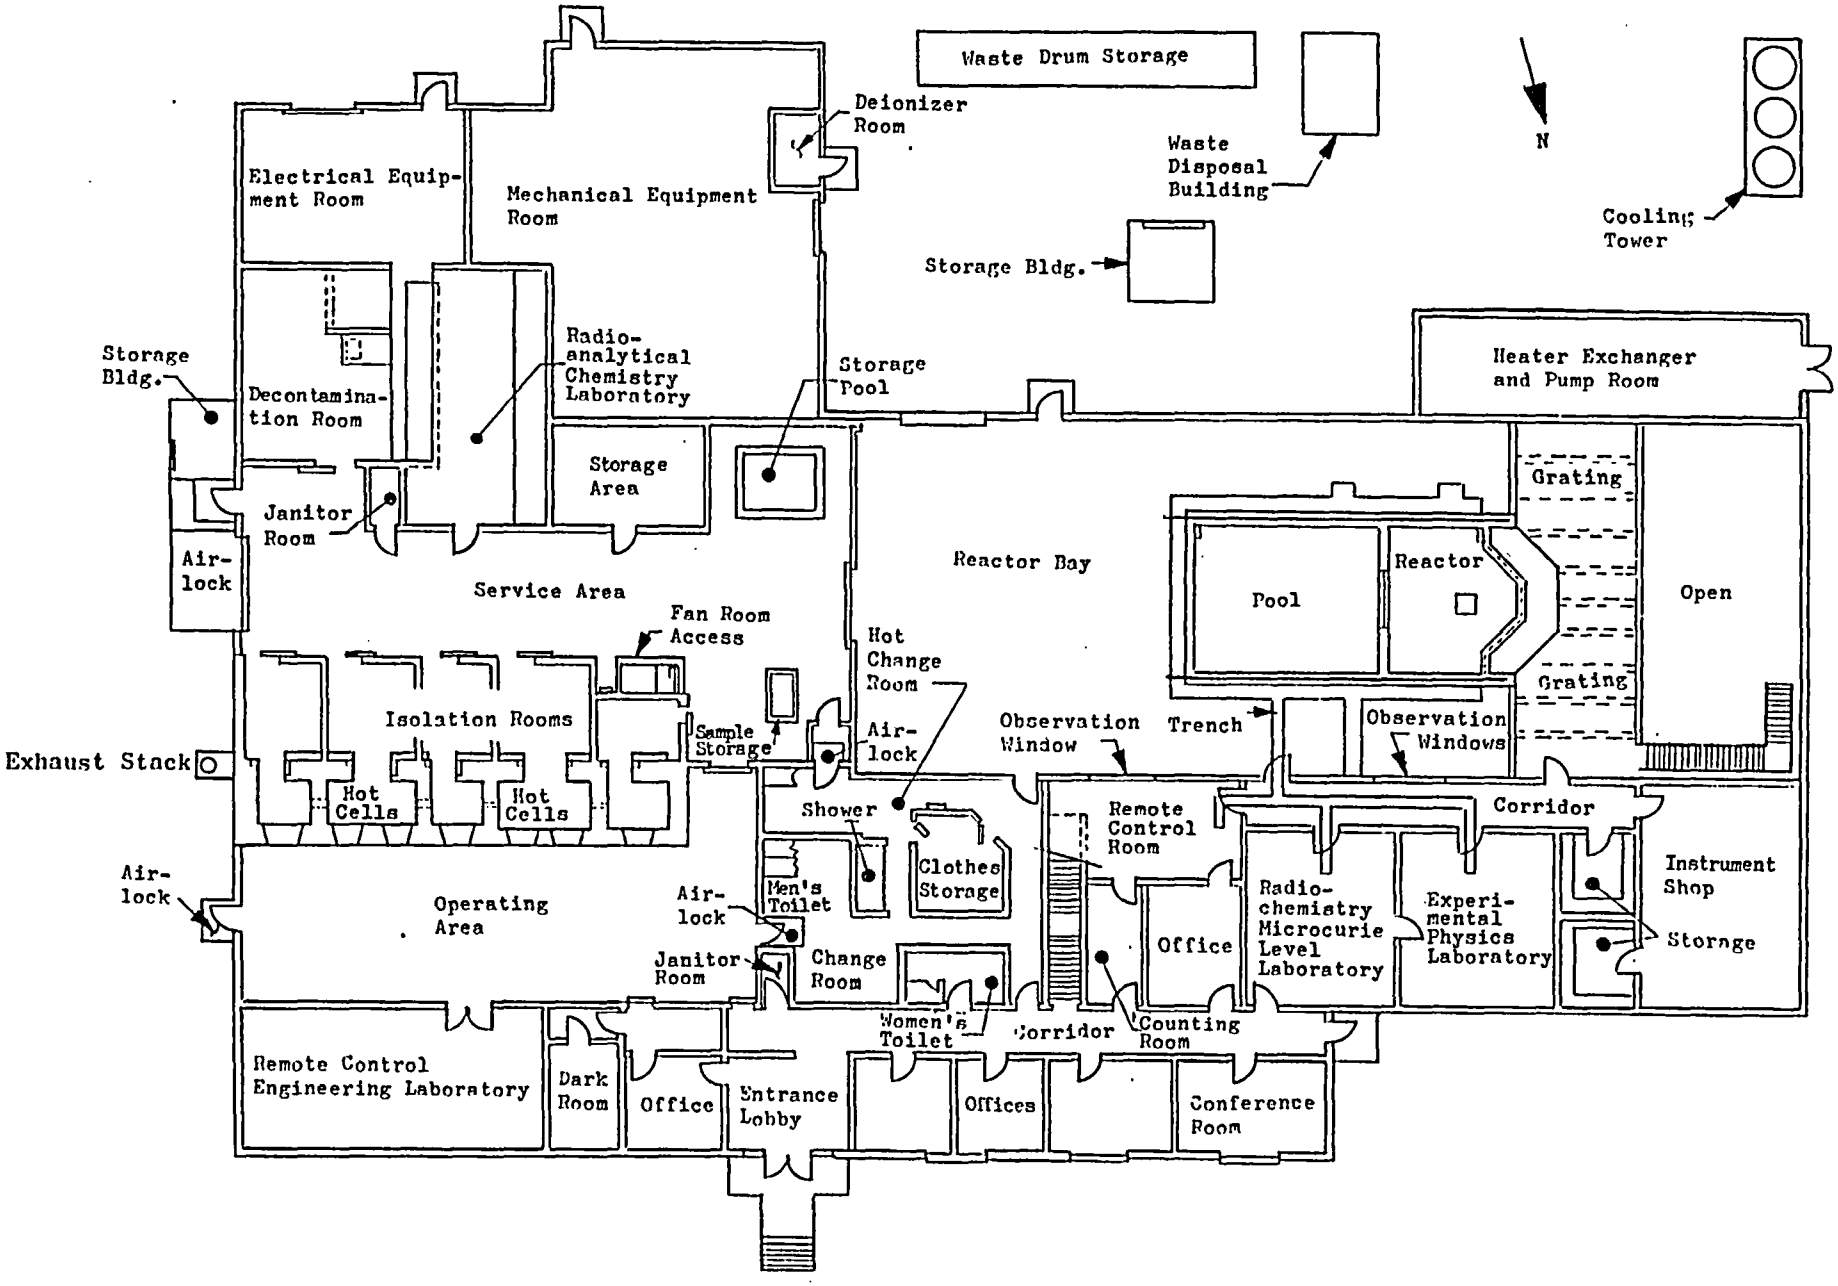


Figure 5.1 Main Floor Plan of Quchanna Nuclear Facility, Showing Radioisotope Pilot Plant in Heavy Outline

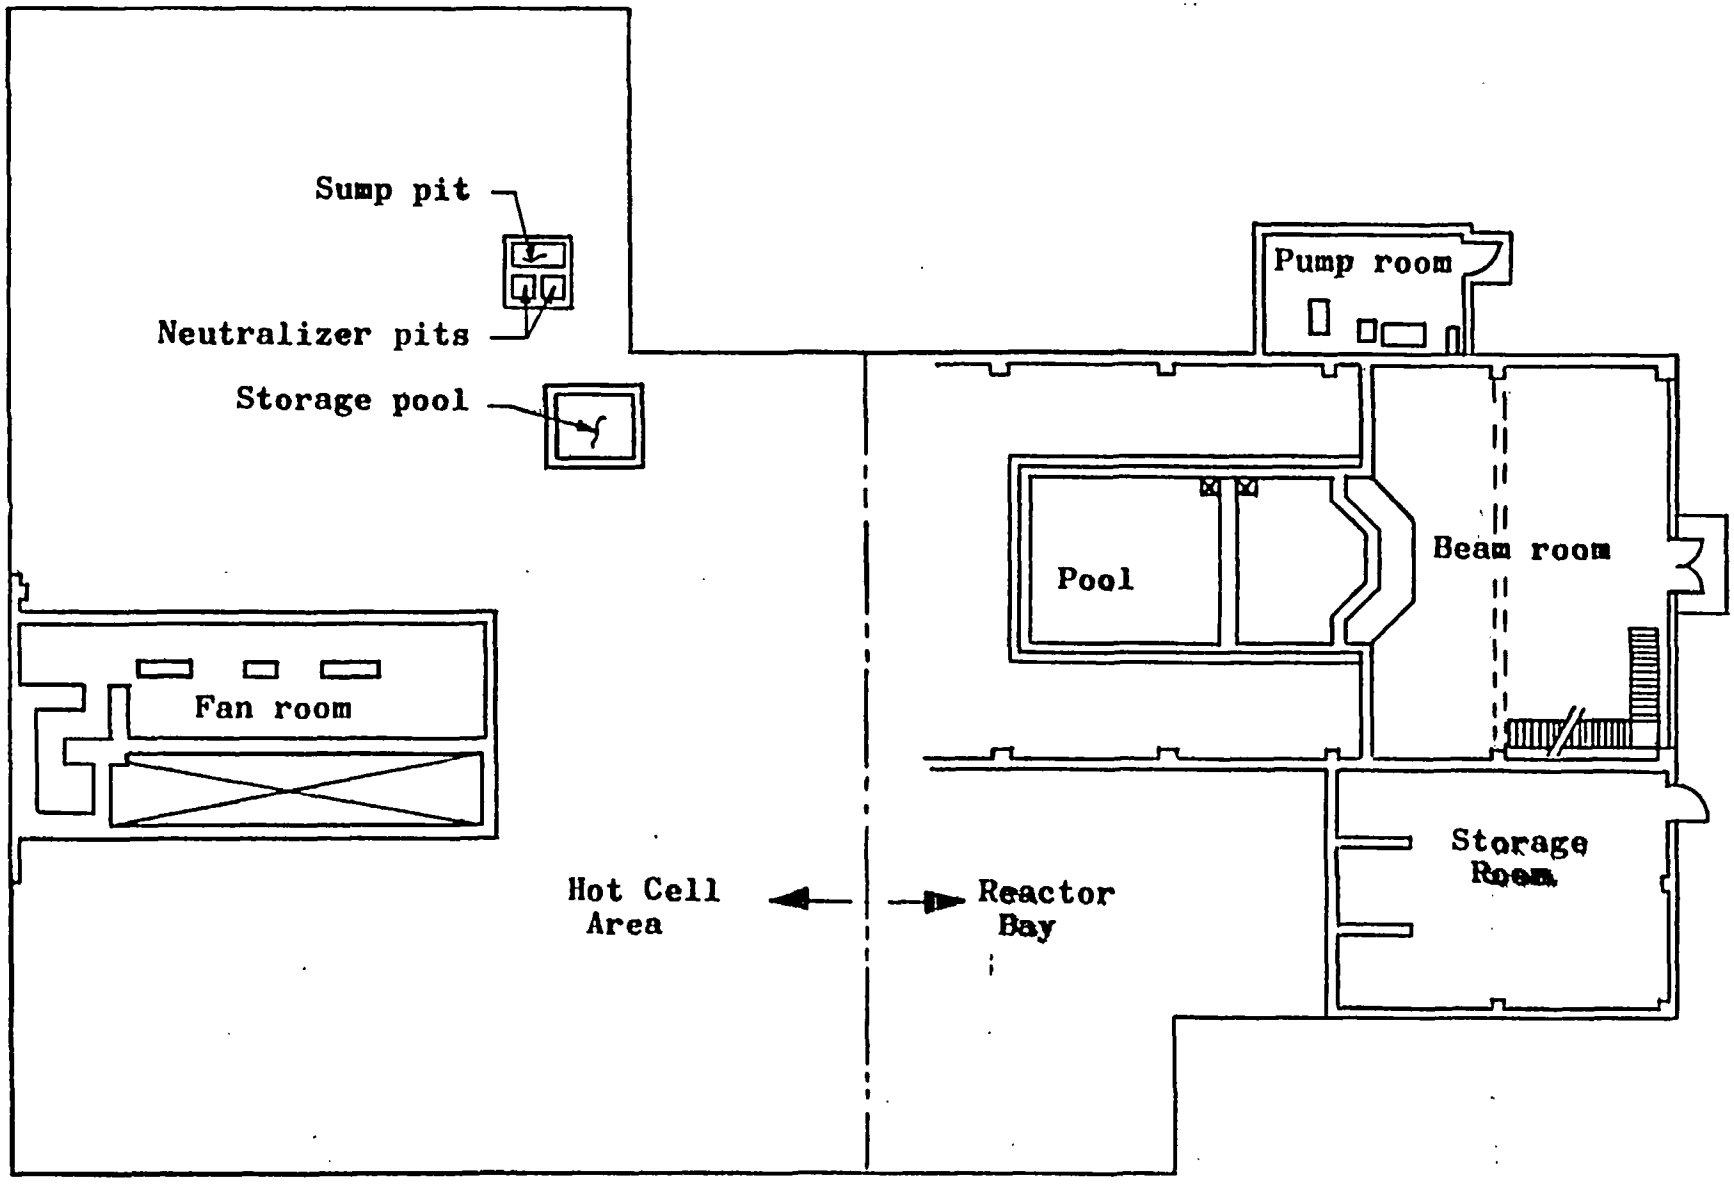

Figure 5.2. Basement Floor Plan of the Quehanna Nuclear Pilot Plant

offices, dark room, staff laboratory, and reactor area. As reference to Figure 5.1 reveals, the only normal access between clean and contaminated areas is via the change room. The large access door between the operating and service areas is normally closed and locked. Because of the relative isolation of the controlled areas, an intercommunication system connecting all parts of the building has been installed.

A more detailed description of that portion of the building with which this report is concerned, the hot cell area, is covered in the following pages. This area, enclosed by the heavy lines in Figure 5.1, includes hot cells, isolation rooms, operating area, service area, radioactive materials storage area, decontamination room, analytical radiochemistry laboratory, and change room and other associated cold areas such as offices and conference rooms. To provide for expansion of the plant in the future, the building was laid out with the entire east wall unobstructed. Additions can be made simply by building additional laboratory space or hot cells in line and extending the operating and service areas.

5.1.2 Philosophy of Multiple Containment

The concept of multiple containment is applied in handling multikilocurie amounts of beta-, and gamma-emitting isotopes of high specific activity. This technique consists of confining the radioisotopes within at least two containment

enclosures. This approach has successfully been used at this facility since July 1962, to prevent the release of particulate activity to the external environment.

The Radioisotopes Pilot Plant is divided into two parts: the administrative area and the hot working area. The operating area is usually maintained in an uncontaminated condition. It is normally accessible only through the change room. The flow of air is progressively from uncontaminated areas to those of increasing likelihood of contamination.

The Martin philosophy of multiple containment is evident throughout the process. Four distinct containment barriers exist:

(a) Process equipment

(b) Steel and plastic process box

(c) Hot cell structure and ventilation system

(d) Building

The first containment barrier is the process equipment itself located within the stainless steel process box inside the hot cells. The process equipment, such as tanks, precipitator, etc., is vented directly through the process box exhaust system.

The second, and most positive, containment barrier is the process box. The box is designed to have the lowest air pressure in the system and is protected by both

absolute type inlet and outlet air filters. In addition, it is designed to have as small an air flow as possible, consistent with a safe operating pressure drop from the cell environment.

The third containment barrier is the hot cell, which also has absolute type filters on both inlet and outlet air streams. The operating air pressure in the cells is higher than that in the process box but lower than that in the operating area. The transfer of material to or from the process box is accomplished by employing a Stationary Overhead Transfer System (SOTS) which prevents the box atmosphere from direct connection to any regions other than the immediate section of the SOTS.

5.2 Area Descriptions

5.2.1 Hot Cells

This facility is comprised of five cells with physical configurations as indicated in Table 5.1.

Table 5.1

HOT CELL DIMENSIONS

Cell No.	Floor Size (ft)	Ceiling Height (ft)	Wall Thickness (ft)
1	6x7	12	3
2	6x12	15	3
3	6x7	12	3
4	8x12	12	2
5	8x8	12	2

Each of these cells is provided with manipulator ports for the use of Model 8 manipulators. In addition, a Kollmorgen periscope may be used. Cells 2 and 4 have two pairs of manipulator port openings so the entire floor area of the process box may be reached. With slight revisions to the port holes, as many as 23 different manipulator locations are possible throughout the five cells. A side elevation of a typical cell is shown in Figure 5.3. A detailed plan view of the cell block appears in Figure 5.4.

The shielding walls of the cells, which reach to a height of 9½ feet above the floor, are constructed of ferrophosphorous concrete with a minimum density of 280 lb/ft^3. Above 9½ feet, the walls are of ordinary concrete, having a minimum density of approximately 150 lb/ft^3. All dense concrete was poured with 1/4-inch steel plate forms which remained in place to form the inner and outer cell wall surfaces. The steel plates simplify decontamination of the cells, afford a good base for attaching fixtures to the interior or exterior, and prevent chipping of the concrete around plugs, drawers, and access ports.

The radiation shielding windows are oil-filled units of 3.6 gm/cm^3 density glass. Each window is roughly the same thickness as the 4.5 gm/cm^3 density wall in which it is installed so that, in comparison to the wall, it is undershielded. This undershielding can be compensated by using an additional

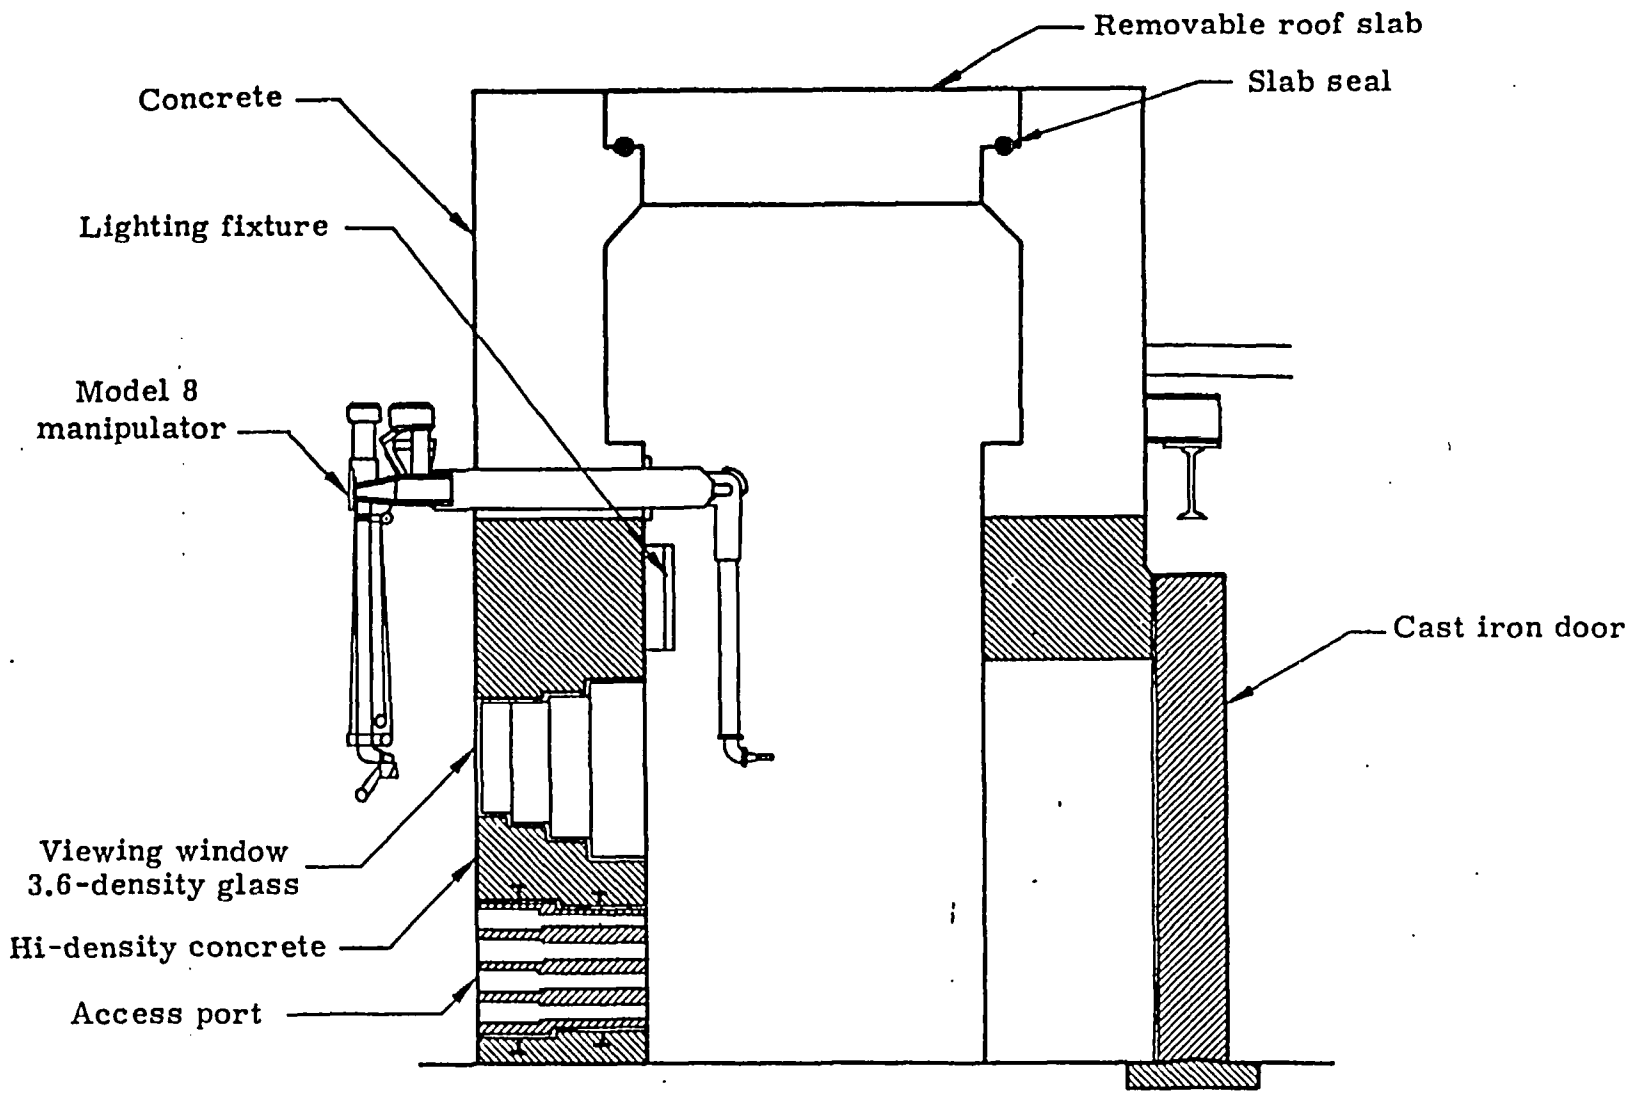

Figure 5.3 Side Elevation--Typical Cell

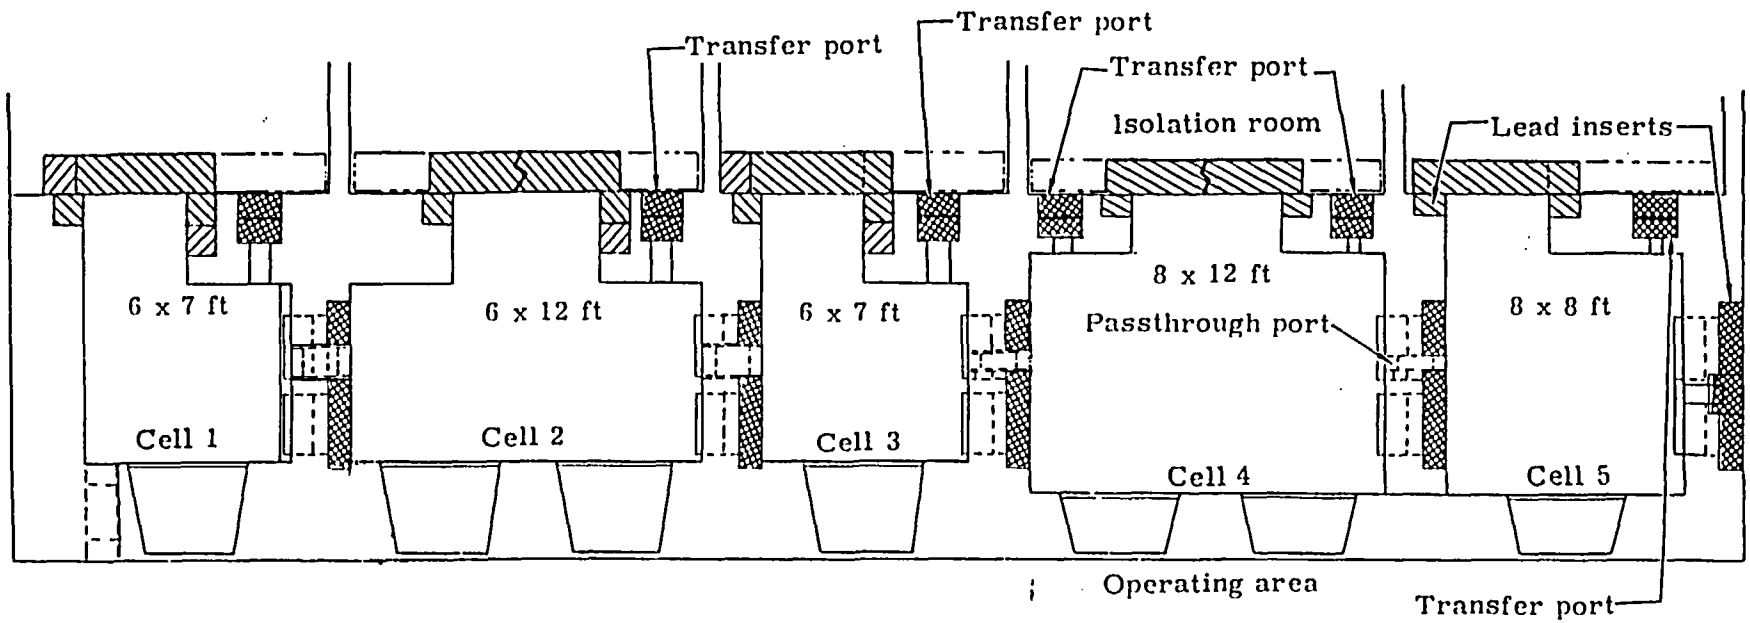

Figure 5.4 Plan View of Hot Cells

slab of 6.2 gm/cm^3 density glass, four inches thick, when additional shielding is required. There are seven windows; two in each of the larger cells and one in each of the remaining three cells. The windows measure 36x48 inches on the hot face, and by virtue of the high refraction index of the glass, permit one to view almost the entire cell area.

The cells may be entered through doors at the rear which open into the isolation room. Details of the door arrangement may be seen in Figure 5.5. As reference to Figure 5.4 reveals, the openings are so placed, and are of such size, that modular equipment tables covering one half (or in the case of the larger cells, one third) of the floor area can easily be removed or rearranged within the cell. This is true of all the cells except Cell 4 where the redesigned isolation room limits access to the cell so that SOTS (see Paragraph 9.2.3) is the only opening for large equipment. Equipment which is too large to pass through the doors (on all cells except 4) may be placed in the cell by removing one or more of the two-foot thick slabs which form the cell roof. By using the 15-ton bridge crane to remove these slabs, the entire cell area may be uncovered if necessary.

Commercial flood lamps supply the cells and process box with the required lighting. Standby or emergency lighting is supplied in all cells so that lamp failures wil not

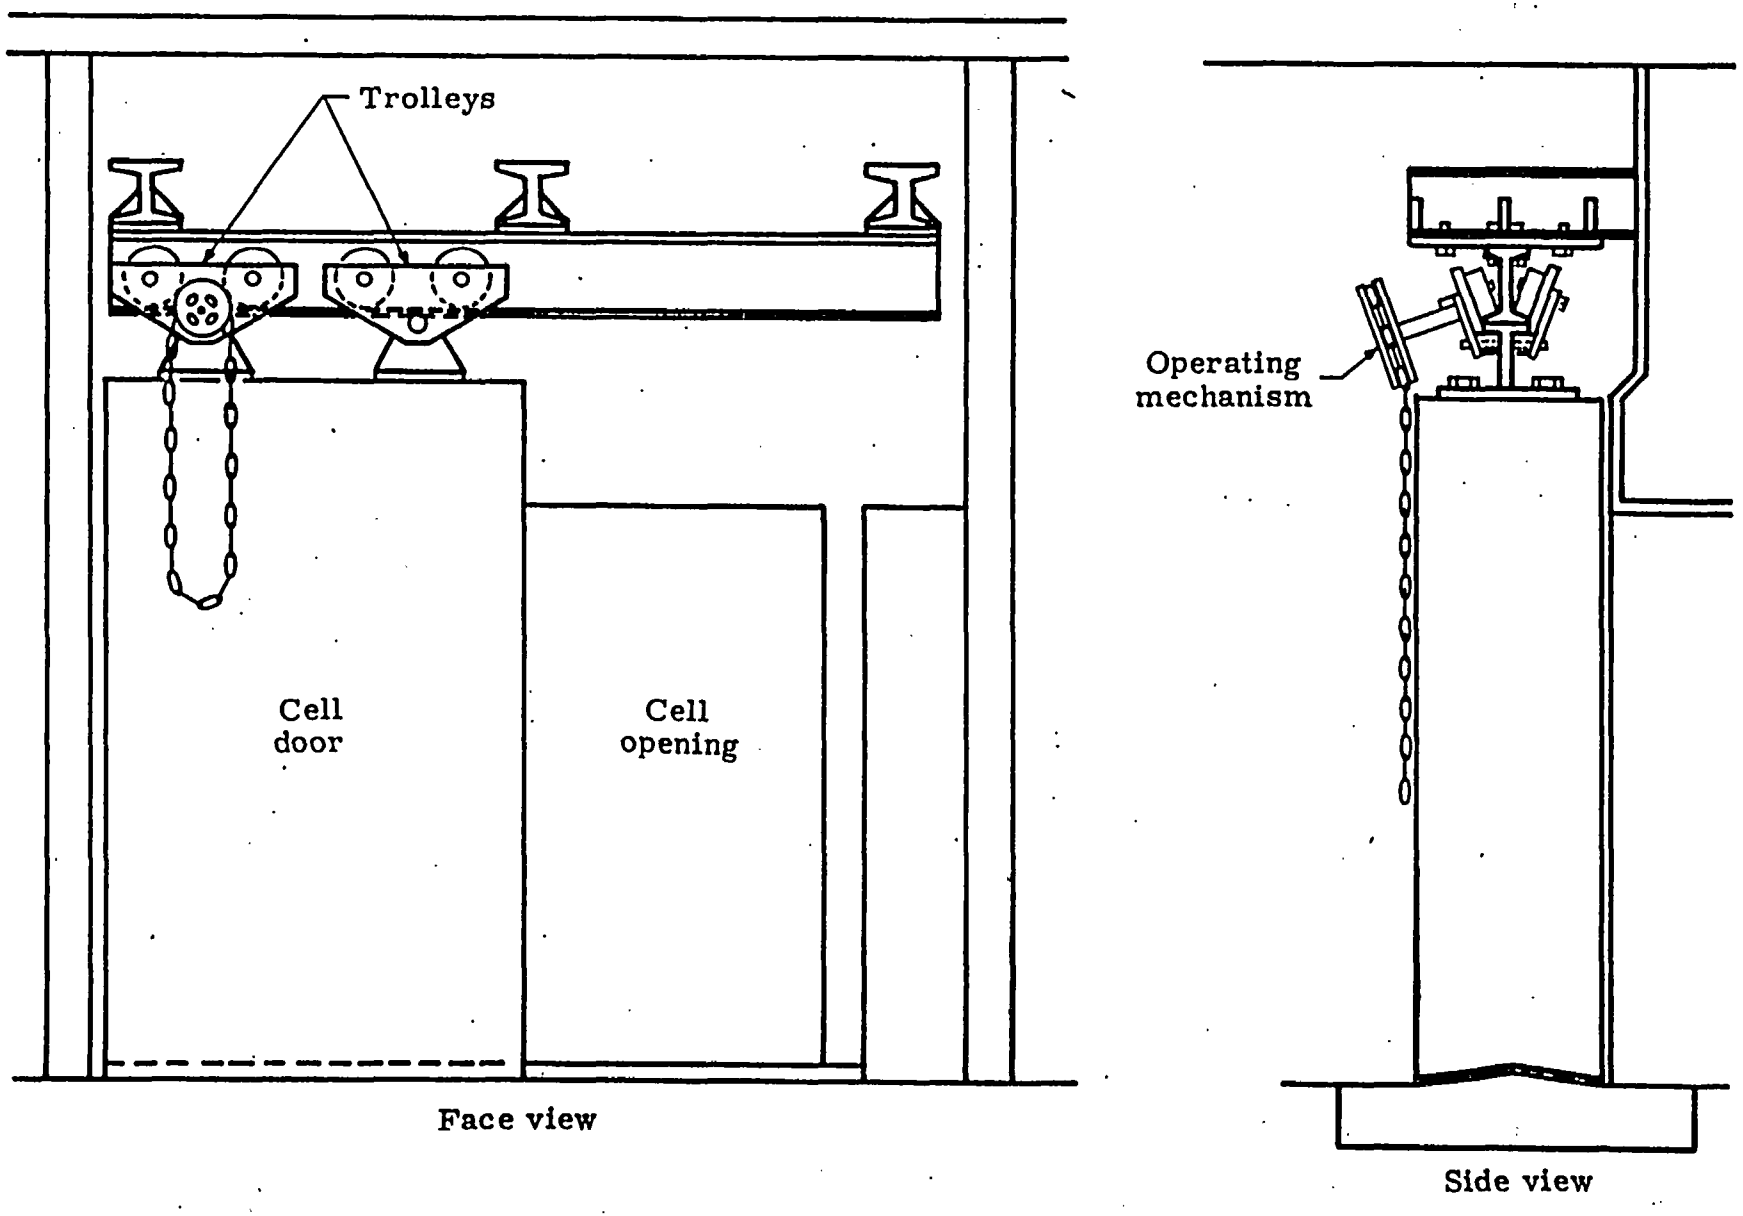

Figure 5.5 Cell Door Detail

cause shutdown. A propane-fueled motor-generator set supplies sufficient power to continue operation of the cell ventilating and lighting systems in case of electrical failure.

The operating faces of the cells are liberally supplied with access ports arranged as shown in Figure 5.6. Many of them have been placed in rectangular drawers or inserts which can be removed and replaced with drawers having plugs designed for specific applications. Individual intercommunication systems connect the operating face and the isolation rooms. There are penetrations from the isolation rooms to the cells and between cells, through which piping and wiring may be passed. All standard services are available in a trench immediately in front of the cell face so that they may be extended through the wall as needed. Channel-through plugs carrying services into the cells are bent so that there is no direct path for radiation from the cell to the operating area. Only a few 110-volt electrical lines are permanently installed within the cells.

5.2.2 Isolation Areas

Figure 5.1 indicates the location of the isolation rooms in reference to the hot cells and the rest of the facility. Table 5.2 indicates the physical configurations.

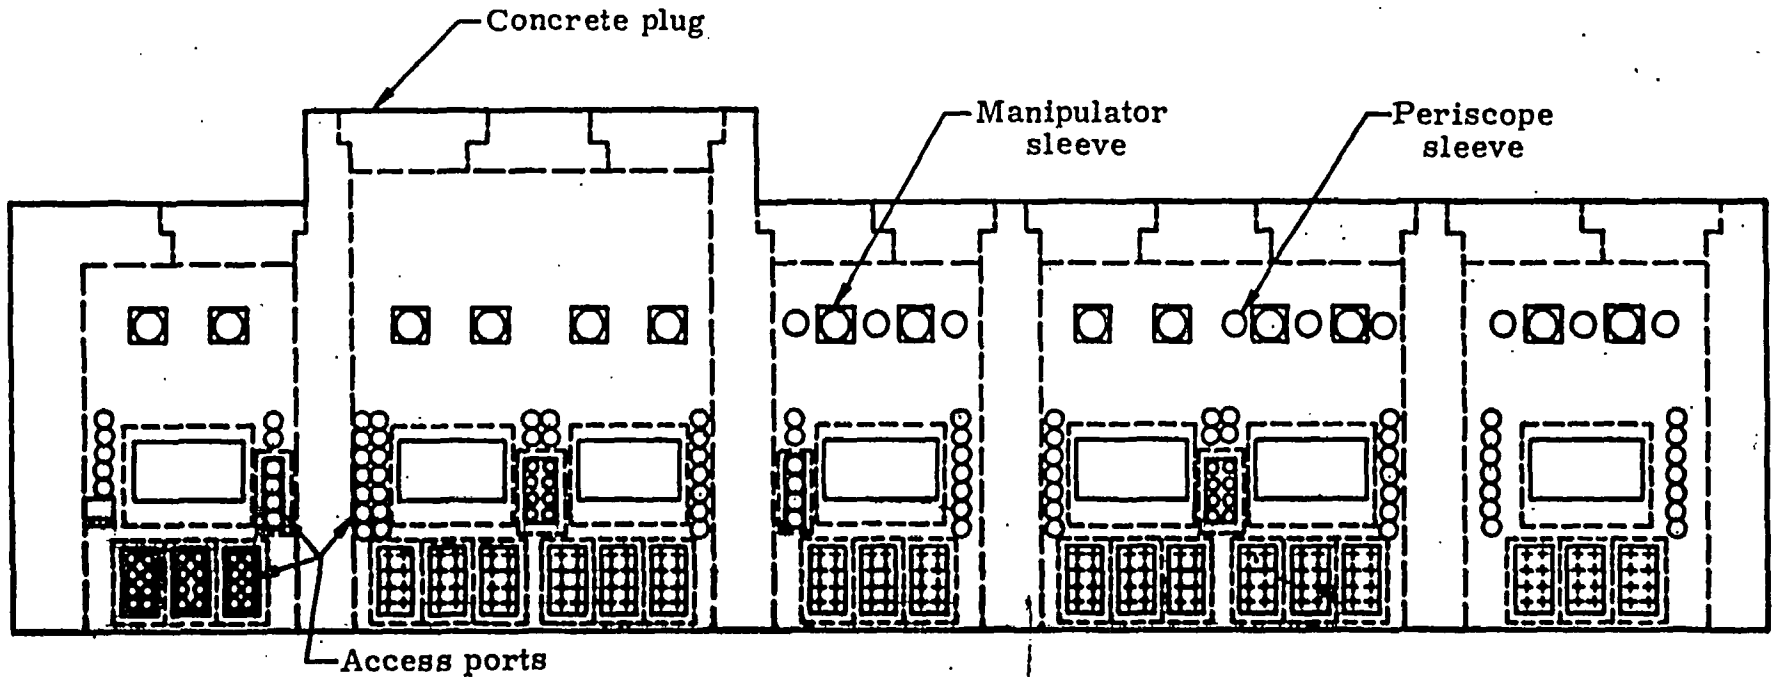

Figure 5.6 Front View of Cells

Table 5.2

ISOLATION ROOM DIMENSIONS

Cell No.	Floor Size (ft)	Wall Thickness (inches)	Ceiling Height (ft)
1	10x14	8	10.67
2	12x14	8	10.67
3	10x14	8	10.67
4	12x14	8	10.67
5	10x10	8	10.67

The walls and ceiling of the isolation rooms are made of precast reinforced concrete. The walls are 8 inches thick and the ceiling 5 inches thick. There are no penetrations in the isolation room surfaces except for the door to the service area and the hot cell door plus sealed conduit pipe for required services.

5.2.3 Operating Area

The operating area is immediately adjacent to the front of the hot cells (Figure 5.1). The walls that form the operating area boundaries are the hot cell walls, the machine shop and metallographic laboratory, the change room, and the exterior wall of the facility. The only normal access to the 20 by 66 foot operating area is through air locks to the change room and to the outside. The door to the outside is part of the integral locking system.

5.2.4 Service Area

The service area is adjacent to the isolation rooms at the back of the cells. The walls that form the service area boundaries (Figure 5.1) are the isolation room, the decontamination room and radiochemistry laboratory and cask storage room, the exterior wall to the facility, and the wall separating the reactor bay from the hot cell area. The only normal personnel access to the service area is again the change room and the outside by way of air locks. The door to the outside is again part of the integral locking system.

5.2.5 Decontamination Room

The decontamination room is adjacent to the service area (see Figure 5.1) and is bounded on the other three walls by the radiochemistry lab, the electrical equipment room, and the outside wall of the facility. The walls to the service area and the electrical equipment room are made of 8-inch concrete blocks and the wall to the radiochemistry lab is a 2-foot thick precast concrete wall. The only access to the 20 by 25 foot room is through the service area.

5.2.6 Radiochemistry Laborstory

The radiochemistry lab is next to the decontamination room and adjacent to the service area (Figure 5.1). Aside from the 2-foot thick precast concrete wall between the radiochemistry lab and the decontamination room, all walls are made of 8-inch concrete blocks. The only access to the 18 by 34 foot room is through the service area.

5.2.7 Storage Area

The storage area (Figure 5.1) is adjacent to the service area and all four walls are of concrete block construction 8 inches thick, approximately 8 feet high, and open at the top. Again the only access to the room is through the service area.

5.2.8 Change Room and Cold Areas

The change room, as mentioned above, is the only way to leave or enter the hot cell area (Figure 5.1). In the change room area are the showers, clothes storage, and the cold area men's toilets. All the walls in this area are 3/4 inch Cemesto board on 2 x 6 inch wood studs. The office area walls are regular construction plaster board on 2 x 4 inch studs. The outside wall of the facility is generally made of insulated aluminum siding applied on a steel frame.

5.2.9 Waste Storage Building

The waste storage building is located about 50 feet south of the plant (Figure 5.1). The prefabricated building, 20 feet by 60 feet, is made of aluminum siding on a steel frame. The building has two roll-up garage type doors which are locked. About one-third of the building has concrete block shielding provided so that the waste drums containing a high level of activity may be stored in this area.

5.2.10 Liquid Waste Treatment Building

The liquid waste treatment building is located about 50 feet south of the plant (Figure 5.1). The 25 x 30 feet building is made of aluminum siding on a steel frame. The building has two doors, which may be locked, one for personnel and one for delivery of supplies and equipment. The building is equipped with a vacuum evaporator system and complete laundry facilities.

5.2.11 Fan Room

The room is located on the lower level, directly under isolation rooms 1-5, (Figure 5.2). The room is 14 ft wide, 57 feet long and 13 feet high. The only entrance is from the service area. Equipment in this area consists of normal, auxiliary and process box exhaust fans and controls, double filter plenum boxes, vacuum pumps and air samples.

5.2.12 Sub-cell (Cell 6)

This room is located on the lower level adjacent to the fan room, directly under Cell 1. It is a heavily shielded room with 2 to 3 foot concrete walls. It is 6 feet, by 6 feet, by 13 feet high with access corridors 3 feet wide. The entire floor area is covered with stainless steel. The only entrances are from the service area through the fan room and through the Cell 1 floor blocks. The entrance door is normally locked and is part of the integral locking system (Paragraph 10.4.3).

5.3 Area Work Assignments

5.3.1 General

The facility has been designed to provide as positive separation as possible between radioactively contaminated and radioactively clean areas. Those areas which will remain free of contamination include offices, dark room, staff laboratory, and reactor area. Potentially contaminated areas include the change room, hot cells, isolation rooms, cell operating area, service area, radioactive materials storage area, decontamination room and storage area. The only normal access between clean and controlled areas is via the change room.

5.3.2 Specific

	Location	Work Assignment
(1)	Cell 1, 2	Being rehabilitated; to be submitted later.
(2)	Cell 3	Solid waste bag-out station.
(3)	Cell 4	Entire fuel processing from precipitation to encapsulation.
(4)	Cell 5	Generator loading, decontamination, thermal output measurement, and capsule storage.

(5)	Isolation Room	Cell 3 - Waste handling Cell 4 - Dissolution of cask feed material; feed storage; feed sampling; and measurement of process tank levels.
(6)	Operating Area	Remote handling of materials and process computations and controls.
(7)	Service Area	Material storage in pool, cask transfer, and cell service.
(8)	Decontamination Room	Decontamination of portable equipment and materials.
(9)	Radiochemistry Lab	Analysis of curie-level quantities of radioisotopes.
(10)	Storage Area	Temporary storage, process water tanks and Health Physics survey equipment.
(11)	Change Room	Personnel change area.

(12)	Office Area	Administration area.
(13)	Waste Storage Building	Temporary storage of waste drums.
(14)	Liquid Waste Treatment Building	Liquid waste processing.
(15)	Fan Room	Ventilation equipment
(16)	Cell 6 (Sub-cell)	Not used

CHAPTER 6

AIR HANDLING SYSTEM

6.1 General Description

Figure 6.1 indicates the areas described in this section and the air flow patterns for these areas. The areas outlined on this drawing include Rooms 102, 103, 105, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118 and 119. All are considered to be in the contained area. All admission to this area is through air locks from outside the building or from adjoining areas.

The contained area is divided into three sub-areas of controlled ventilation served by Supply Air Systems 3, 5 and 7. The areas outside the contained area are served by separate supply and exhaust systems. The airflow pattern within the contained facility is from the machine shop (119) to operation area (118), operation area (118) to service area (107), service area (107) to isolation area (108-112), isolation area (108-112) to cells (113-117), and cells to dry boxes. Most air supplied to the service area is exhausted through the cells, through at least two absolute filters in series, and then to the outside through the main stack. During normal operation, the operation area is at atmospheric pressure or marginally positive, the service area slightly negative, and increasingly more negative pressures in the isolation room, cell and dry

box, in that order. The cell in which unsealed fuel is handled has, in addition to the shielding door an absolute type filter to allow airflow into the cell.

The areas outside the contained area are served by separate supply and exhaust systems. For example, system 10, serving the decontamination room, receives its air supply from the service area and discharges to the atmosphere through its own fan and set of high efficiency filters. System 7, which serves the radiochemistry laboratory, has its own outside air supply fan and its own exhaust fan.

Emergency control systems may be actuated manually or automatically. Three emergency buttons will shut off all contained area supply fans. They are located in the service area, operating area and outside the main entrance. Continuous air monitors provide constant monitoring of the air of various areas (see Paragraph 10.5.3.2). Upon alarm of these, control mechanisms are automatically brought into play.

6.2 Ventilation Subsystems Description

Descriptions of the following systems are found on Figure 6.2, Table 6.1 and Table 6.2.

6.2.1 System 3 - Service Area Air Supply

The oil-fired space heater SH-2 located in room 107, the service area, is set to provide a constant supply of outside air. A pneumatic backdraft damper opens and closes

Return air to 118 and 119 = 4755 cfm

as the fan is started and stopped. From the heater, air passes through four outlet ducts, each equipped with a backdraft damper. Under an emergency condition, this fan will shut down, the outside air damper will close (intake side of SH-2) and the four weighted backflow dampers on the positive side of SH-2 will close. As soon as the emergency has cleared, SH-2 will return to normal automatically when the activating monitor is reset. Most of the air exhausted from the service area is eventually exhausted through the cells; the remainder is exhausted through the decontamination room (102).

6.2.2 System 5 - Machine Shop and Operating Area

Supply fan UC-2 supplies a mixture of outside and recirculated air to the operating area and machine shop. Thermostatically controlled dampers located in the intake duct for UC-2 and the return duct from exhaust fan E-11 regulate the air supplied to UC-2. A pneumatically operated damper opens and closes as the fan is started and stopped. A static pressure regulator modulates the inlet damper to fan UC-2 to maintain a constant air supply to the supplied areas.

Air from the operating area is monitored (M-4) as it enters the exhaust duct, serviced by fan E-11. The inlet vanes to this fan are locked wide open to provide maximum air exhaust from the operating area. Air which is not recirculated leaves the building through an exhaust stack provided with a backflow damper.

6.2.3 System 7 - Radio Chemistry Laboratory

Supply fan UV-2 furnishes only outside air to the radio chemistry laboratory. Air from this laboratory is exhausted to roughing and high efficiency filters through fan E-12 to the outside of the facility. Two backflow dampers are provided in the exhaust duct to prevent air from being drawn into the room from the hoods under emergency conditions. On a drop in space temperature, the room thermostat will control the face and by-pass dampers to maintain 70°F. When room temperature rises, the face damper will close. The low limit in the fan discharge may take command away from the room thermostat and open the face damper to prevent the temperature from dropping below 60°F. When the fan is not operating, the face damper will remain closed. A filter paper sampler is located downstream of E-12 and a final backflow damper is located in the exhaust stack.

6.2.4 System 8 - Hot Cell Exhaust

6.2.4.1 Main Cell Exhaust

The main exhaust system from each cell takes air from the service area through the isolation rooms into the cells (see Figure 6.3). The air leaving the cell passes through a roughing filter, two high efficiency filters in series through the main cell exhaust fan, to a common header and finally to the stack. The static pressure regulator for each cell will

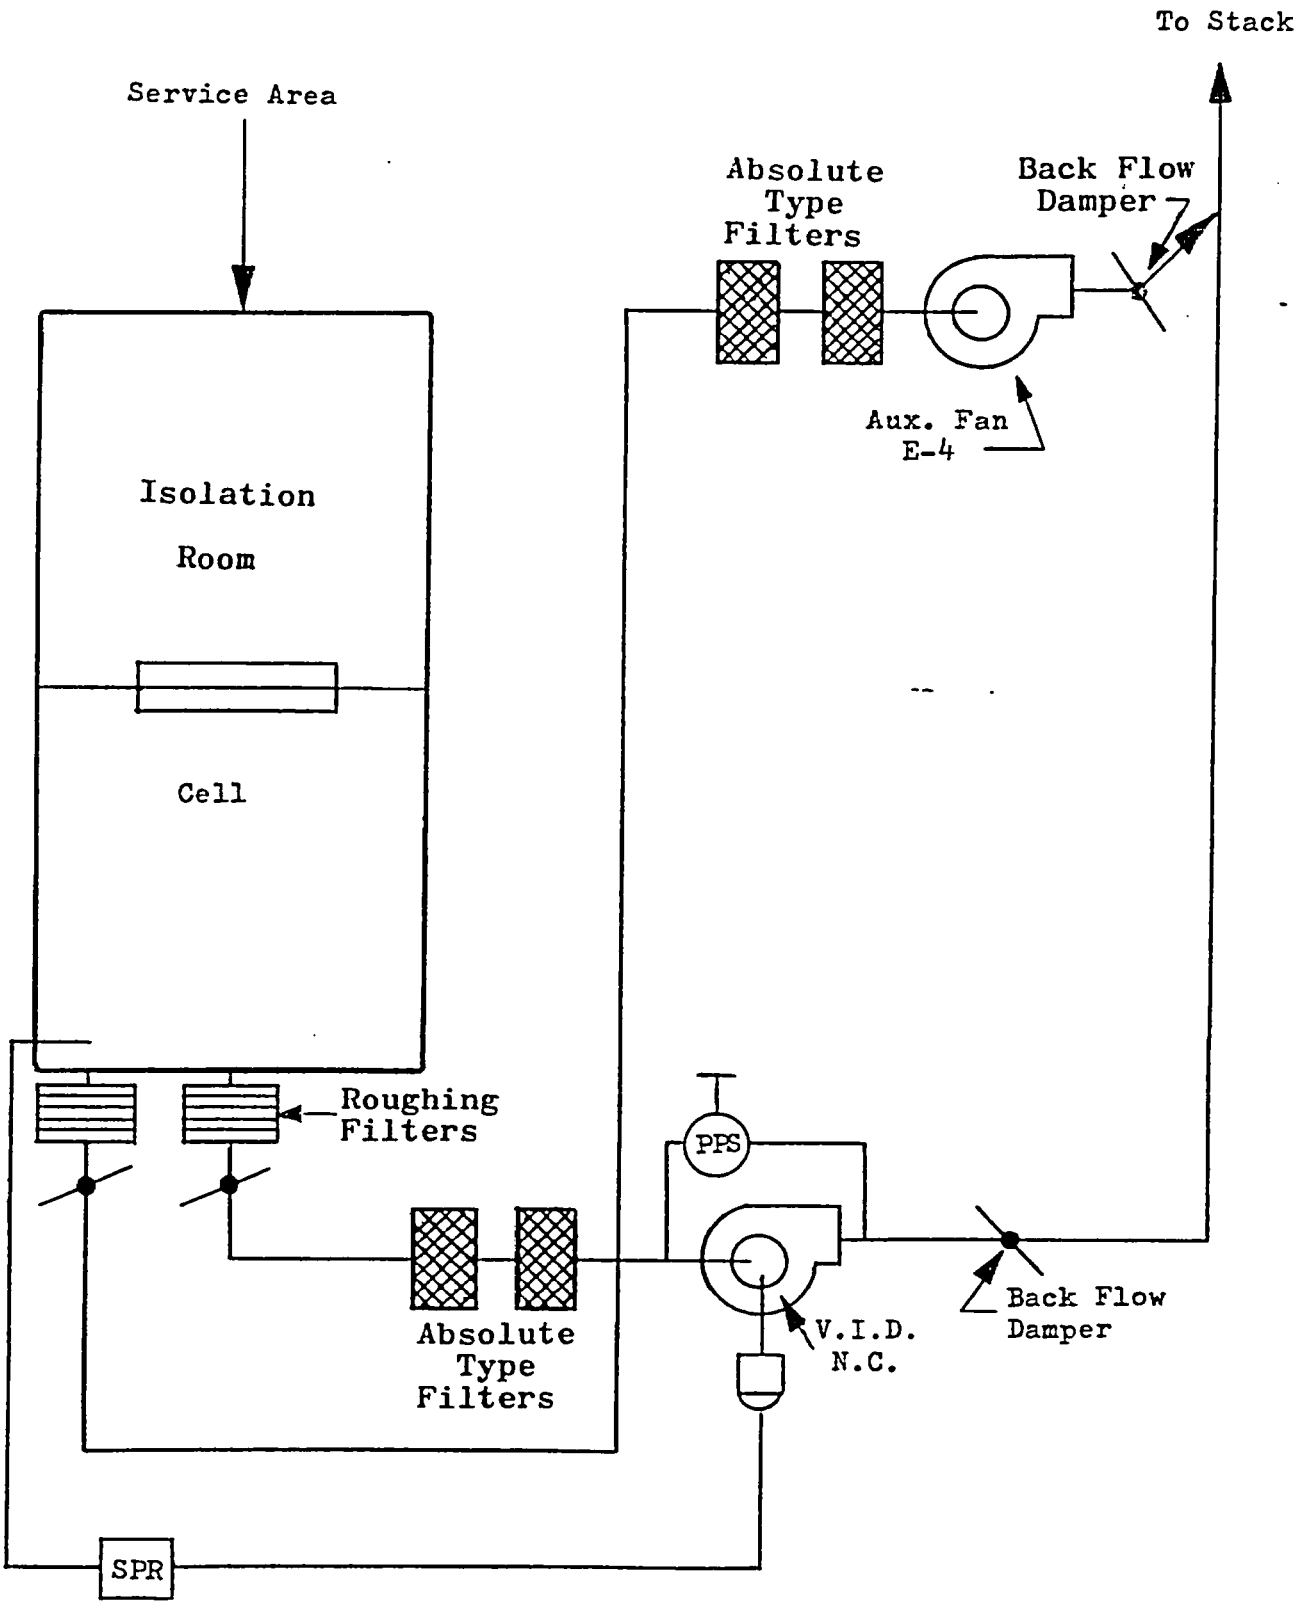

Figure 6.3 Typical Hot Cell Exhaust

modulate the vane inlet damper of the main cell exhaust fan to maintain the required static pressure. If the static pressure rises above the throttling range of the regulator, the auxiliary exhaust fan E-4 will operate and the auxiliary cell intake damper will open. There is about one complete air change per minute in all cells.

6.2.4.2 Auxiliary Cell Exhaust

Usually the normal exhaust fan will be in operation with its intake damper open. However, if the pressure difference across this fan decreases, indicating the possibility of a failure, fan E-4 will start, the auxiliary damper will spring open and the main damper will be motor closed. Air is then exhausted from the cell through a roughing filter and two high efficiency filters in series in the auxiliary exhaust system.

6.2.5 System 9 - Process Box

The air supply to the process box is taken from the cell. (Figures 6.4, 6.5 and 6.6). A differential pressure switch indicates differential pressure across fan E-13. Dampers are adjusted to maintain the box at a negative pressure with respect to the cell. The pressure differentials are given in Table 6.3 and the air velocities associated with the differential pressures are given in Table 6.4. The supply air enters the box through a manifold with two high efficiency filters in parallel. Valves enable use of one filter at a time, the other filter being a spare.

11.	4B to 4A (in Process Box)	3.77

*If leakage in the SOTS walls occurs

The box has dual exhaust ducts installed in parallel. Each duct has a high efficiency filter. The exhaust air, after leaving the box, passes through an additional high efficiency filter which is located at the rear of the box inside the cell door. The filter is accessible for changing. The box exhaust then enters the permanent system, passes through two high efficiency filters, through E-13 or E-14 and then to the stack.

Normally the fan E-13 will be in operation with the fan E-14 acting as a standby.

With fan E-13 in operation, the intake damper is open. If the differential pressure switch senses a loss in pressure differential across the exhaust fan E-13, relay R-30 contact will open, causing the control circuit for fan E-13 to be de-energized, making a circuit to exhaust fan E-14 and causing it to start, opening its intake damper, and breaking an interlock so that the exhaust fan E-14 will continue to run and E-13 will not try to restart even through the correct pressure difference has been re-established. An alarm will sound to indicate that all the foregoing has taken place.

6.2.6 System 10 - Decontamination Room

Supply air is drawn into room 102 by fan E-15 from the service area through louvers in the door and exhausted to the outside through roughing filters and high efficiency

filters. A backflow damper is provided to prevent leakage back into the hood during emergency conditions.

The velocity pressure regulator VPR-1 will modulate the vane inlet damper motor DM-16 to maintain velocity pressure.

6.3 Normal Operations of Cell Exhaust

The cell exhaust systems are started by one push button located in the motor control center. Fans E-4 through E-10 have individual resets located in the motor control center. This main starter button starts fans E-5 through E-10 with a time delay (15 seconds) before fan ~~8E-2~~ starts.

A time delay on the differential pressure switch on fans E-5 through E-10 prevents operation of the auxiliary exhaust fan E-4 before the system stabilizes.

There is a differential pressure switch across each cell exhaust fan. On loss of differential pressure due to fan failure, the pressure switch causes the normal damper to close (motorized damper prior to first high efficiency filter) and the weighted back draft damper beyond the fan will close. The auxiliary damper will spring open on that particular cell and auxiliary fan E-4 will start. An alarm sounds, indicating that cell pressure has been lost and the auxiliary fan E-4 has started.

A static pressure regulator connected between each hot cell and the outside atmosphere maintains a negative pressure by modulating the variable inlet vanes at the fan. If the fan is unable to maintain this negative pressure by vane modulation because of an open door or a dirty filter, a pneumatic electric switch will start auxiliary fan E-4 and open the associated auxiliary duct damper on that particular cell. Both the normal cell fans and the auxiliary fan are thus exhausting that cell.

6.4 Method of Operations

With all supply air fans (E-15, SH-2, UC-2, E-11, UV-2, E-12) in operation, and all cell fans (E-5 through E-10 and E-13) operating normally, the auxiliary fan E-4 and E-14 should be stopped.

As previously stated, the main manual push button to control this system is located in the motor control center. Therefore, for any initial start-up this button should be in the OFF position and all switches on the control board shall be turned to AUTOMATIC. The system can now be properly operated by switching the button in the motor control center to ON. All cell fans will start and after a 15 second delay the supply fans will start.

6.4.1 Static Pressure Regulator

The static pressure regulator senses the static pressure differential between the cells and operating area. It provides contacts which begin corrective actions in case the cell static pressure is lost. Gauges associated with the static pressure regulator are normally set at 5 psi or lower operating pressure. Upon loss of cell static pressure, these gauges rise to about 11 psi or a little higher. This pressure actuates the E-4 (auxiliary fan) switch, fan E-4 starts and the associated cell auxiliary duct damper opens.

6.4.2 E-4 Switch

The E-4 switch is connected to the static pressure regulator and, upon activation, causes fan E-4 to start and associated cell auxiliary duct damper to open.

6.4.3 Pneumatic Electrical Switch Reset

When cell static pressure has built up to normal again and can be maintained by the normal cell fan, pushing the pneumatic electrical switch reset turns off fan E-4 and closes the associated cell auxiliary duct damper returning the cell ventilation systems to normal.

6.4.4 Differential Pressure Switch

Any loss of differential pressure across the normal fans is sensed by this differential pressure switch in the basement fan room. In case of fan failure, it closes the

associated normal cell duct damper, opens the associated cell auxiliary duct damper and causes fan E-4 to start. Such action is displayed on the annunciator panel.

6.4.5 Differential Pressure Switch Reset

Upon establishment of pressure differential across a fan, pushing the differential pressure switch reset causes fan E-4 to stop, the normal cell damper to open and the associated cell auxiliary duct damper to close, returning the cell ventilation condition to normal.

6.4.6 Hays Gauges

(a) Gauge A displays differential pressure across the first high efficiency filter in the normal cell exhaust duct.

(b) Gauge B displays differential across the cell auxiliary pre-filter.

(c) Gauge C displays differential pressure across the normal cell pre-filter.

(d) Gauge D displays differential pressure across the second high efficiency filter in the normal cell exhaust.

There is no automatic corrective action associated with these differential pressure gauges.

6.4.7 Process Box Control Section

(a) The process box control section of the panel contains the same type of Hays gauges as the rest of the panel to measure the pressure differential across the two final high efficiency filters.

(b) Three magnehelic vacuum gauges are located here to display the operating conditions of three vacuum pumps located in the fan room. These pumps supply vacuum for a filter paper sampling system integrated with the ventilation system.

6.4.8 Auxiliary Fan Control Section

(a) The auxiliary fan control section contains two Hays gauges which display the pressure differential across the two associated high efficiency filters.

(b) It contains one differential pressure switch reset controlling resetting of fan E-13.

(c) It contains one alarm contact, connected to the annunciator panel, which makes contact and sounds an alarm whenever fan E-4 is actuated.

6.5 Emergency System Control

6.5.1 Manual

In the event of any gross contamination within the contained area, all supply air must be shut down insuring that the pressure will remain lower than that of the other areas and the direction of air flow is always toward areas of increasing contamination.

There are three manually operated push button emergency stations; one is located in the service area air exit (east end of building), one is in the operating area at the air lock to the change room and a third button is located on the outside of the main entrance doors.

Activation of any of these manual buttons will stop all fans supplying the contained area. The specific fans involved are:

(1) E-15 - Exhaust air from Decontamination Room 102

(2) SH-2 - Air to Room 107 - Service Area (overhead oil burner)

(3) UC-2 - Air to Machine Shop and Operating Area

(4) E-11 - Air to exhaust from Machine Shop and Operating Areas

(5) UV-2 - Air to Radiochemistry (103)

(6) E-12 - Air exhaust from Radiochemistry (103)

To restart the air supply system the same manual button that was activated will have to be reset. After resetting this manual button, all fans will start automatically except for the following:

(1) UC-2, E-11 - Reset on equipment mezzanine

(2) E-15 - Reset on mezzanine above Decontamination Room 103

(3) Reset on all pneumatic electrical switches and differential pressure switches - Buttons on control panel board

A weighted backflow damper is located in the wall between Rooms 118 - Operating Area and 107 - Service Area. Under normal conditions, this damper will be closed. Under emergency conditions, this damper will be open to purge the operating area.

6.5.2 Monitoring Systems and Controls

Constant air monitors control the air handling systems to assist in the prevention of the spread of contamination. The details of their operation are found in Paragraph 10.5.3.2.

6.6 Stationary Overhead Transfer System Ventilation Plan

6.6.1 Secondary Inlet Air

A 500 cfm absolute type filter will be placed in Cell 3 with a manual 6-inch damper on the inlet which can be operated from the face of the cell. A 6-inch diameter tube will lead from the filter, through the top of Cell 3 into the SOTS secondary containment near Cell 3. That will insure that the secondary containment will be held at a pressure approximately equal to, or less than, the pressure in Cell 3.

6.6.2 Primary Inlet Air

An automatic damper will be installed behind a roughing filter between the primary and secondary SOTS containment near the Cell 3 downcomer door in a manner to make both the filter and damper accessible.

The above damper-filter will be designed to control the pressure drop across the two stages of containment.

6.6.3 Primary Air Exhaust

The inner SOTS containment will be exhausted through filters of at least 100 cfm capacity to the Cell 3 box exhaust system.

The SOTS exhaust duct will originate at a spot high in the inner containment with a 4-inch diameter duct coming down between the two containment barriers and through the Cell 3 roof area. Filters will be set up in parallel with a damper system to permit filter changes while maintaining an uninterrupted air flow.

6.6.4 Pressure Differential - Measurement

Two differential pressure gauges will be installed on the cell face for SOTS. One will indicate the differential between the outer containment and operations and the other will show the differential between the inner containment and operations. A similar system will be provided for the Cell 4 process box.

6.6.5 Ventilation During Transfers

6.6.5.1 Attachment of Drum Liner

The drum and new drum liner will be attached to the SOTS Cell 3 downcomer. A bleed valve will be provided on the downcomer to permit air from the cell to enter the downcomer and a magnehelic gauge will be provided on the downcomer proper to permit visual determination of negative pressure. The internal downcomer pressure will be reduced to permit correct attachment of the drum liner.

6.6.5.2 Pressure Equalization

The Cell 3 SOTS door would be opened and the waste container taken up to SOTS and the Cell 3 door would be closed. At this point, the SOTS inlet damper would be partially closed and the pressure in SOTS would be lowered until the inner pressure reached 0.05 to 0.1 inch water gauge positive with respect to the process box; the box door would then be opened and the transfer made. At no time will SOTS be allowed to become negative with respect to the box, nor will more than one of the SOTS doors be open at one time.

CHAPTER 7

WASTE DISPOSAL SYSTEM

7.1 Description of Facilities

Facilities are available for the control, treatment and disposal of airborne, liquid and solid radioactive wastes.

7.1.1 Solid Wastes

As far as possible, all wastes are converted to solid form and suitably packaged for shipment and ultimate disposal by land burial. Airborne particulates are removed by filtration. When the accumulated solids on the filter begin to impair its flow capacity or reach a radiation level designated as the maximum for operation, the filter is replaced. The old, contaminated filter is removed from the system and packaged in a disposal container for shipment and burial. In similiar fashion, concentrated radioactive liquid process wastes, after neutralization, are absorbed in a suitable medium, such as Flor-co, a commercial product which can absorb about 4 times its own weight of liquid, in the proper proportion to form a monolithic solid. The absorbing mixture is preloaded in the disposal container; after the liquid waste has been added, the container can simply be sealed for shipment.

The disposal containers, which are approved by the Bureau of Explosives, consist of steel drums (see Paragraph 9.1.3.2). For disposal of solids, the inner cavity is filled to

capacity (dictated by either mass of material or radiation level), the inner cover put on, the top cavity filled with concrete, and the outer drum cover put on. For disposal of liquids, the inner drum cavity is preloaded with Flor-co and the cover with valved inlet and vacuum line put in place. When the waste liquid has been added, the valves are then closed and the line to the waste storage tank disconnected. Concrete is poured into the top cavity and the top cover put in place. Thus, for liquid process waste disposal, it is necessary only to drain the liquid into the previously prepared drum. The drum for liquid waste is located in the isolation room of Cell 3 and connected to the process lines by appropriate plumbing. For removal of the loaded drum to storage and shipment, the isolation room is entered, the drum removed, and a new drum connected in place.

The solid wastes are removed from the process boxes in specially designed transfer boxes (see Paragraph 9.1.2.4 for specifications) which are transported to Cell 3 by SOTS. The waste is placed in drums using the solid waste bag-out system (see Paragraph 9.1.5.1).

7.1.2 Liquid Wastes

The previous section indicated how high level liquid process wastes are transposed to solids for ultimate disposal. This is practical for the relatively small volume of liquids handled in the process. There are relatively large volumes of low level liquid wastes generated in operations auxiliary to the

process, for which the previously described liquid treatment is too costly. A liquid waste treatment plant is available for disposal of this latter category of waste. In this plant, the low level wastes are tested for activity by a Pennsylvania State University Health Physics representative. If a reasonable amount of dilution will lower the activity level to within the specified limits of 10CFR20, the wastes are diluted and discarded to the stream system (see Figure 7.1). If this method is not possible, the liquid is vacuum evaporated to provide a condensate of sufficiently low level contamination for discharge to the streams. The high level residual liquid remaining in the evaporator is disposed of by the above described method of conversion to a solid.

The plant for treatment of low level liquid wastes is housed in a separate building about 50 feet from the main building. The capacity of this plant is based on an estimated flow of 300 gal/day, of which about 10% might actually require evaporation treatment. In actual experience the plant has safely and efficiently processed 15 gal/hr. by evaporation.

Figure 7.2 shows that wastes flow to the treatment plant by way of two collection systems. The low level waste system originates in areas of potential radioactive liquid wastes and contamination such as the radio-chemistry laboratory drains and the fume hoods in the decontamination room. Drains from areas of unlikely, but possible, radioactive contamination

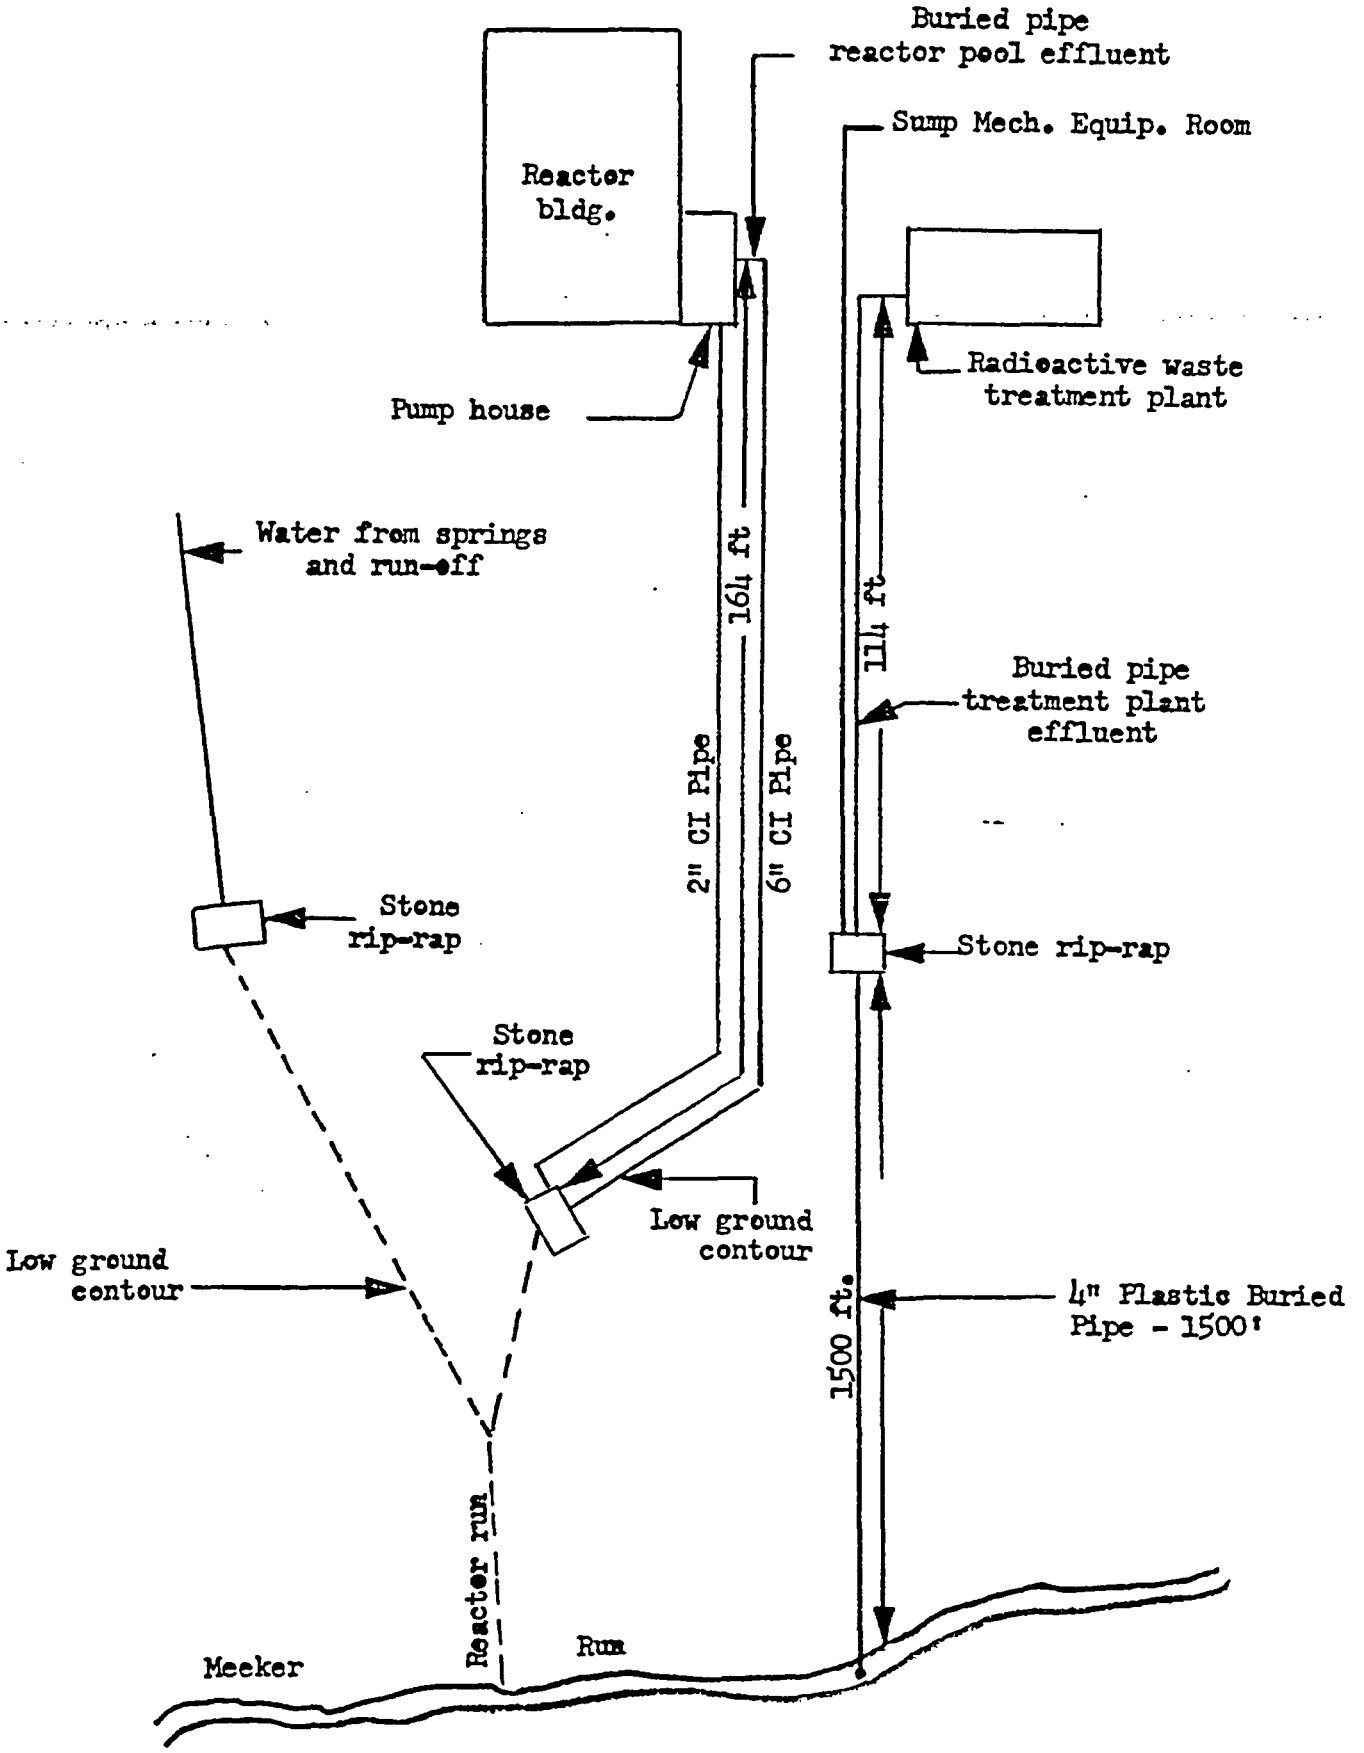

Fig. 7.1 Waste Treatment Runoff

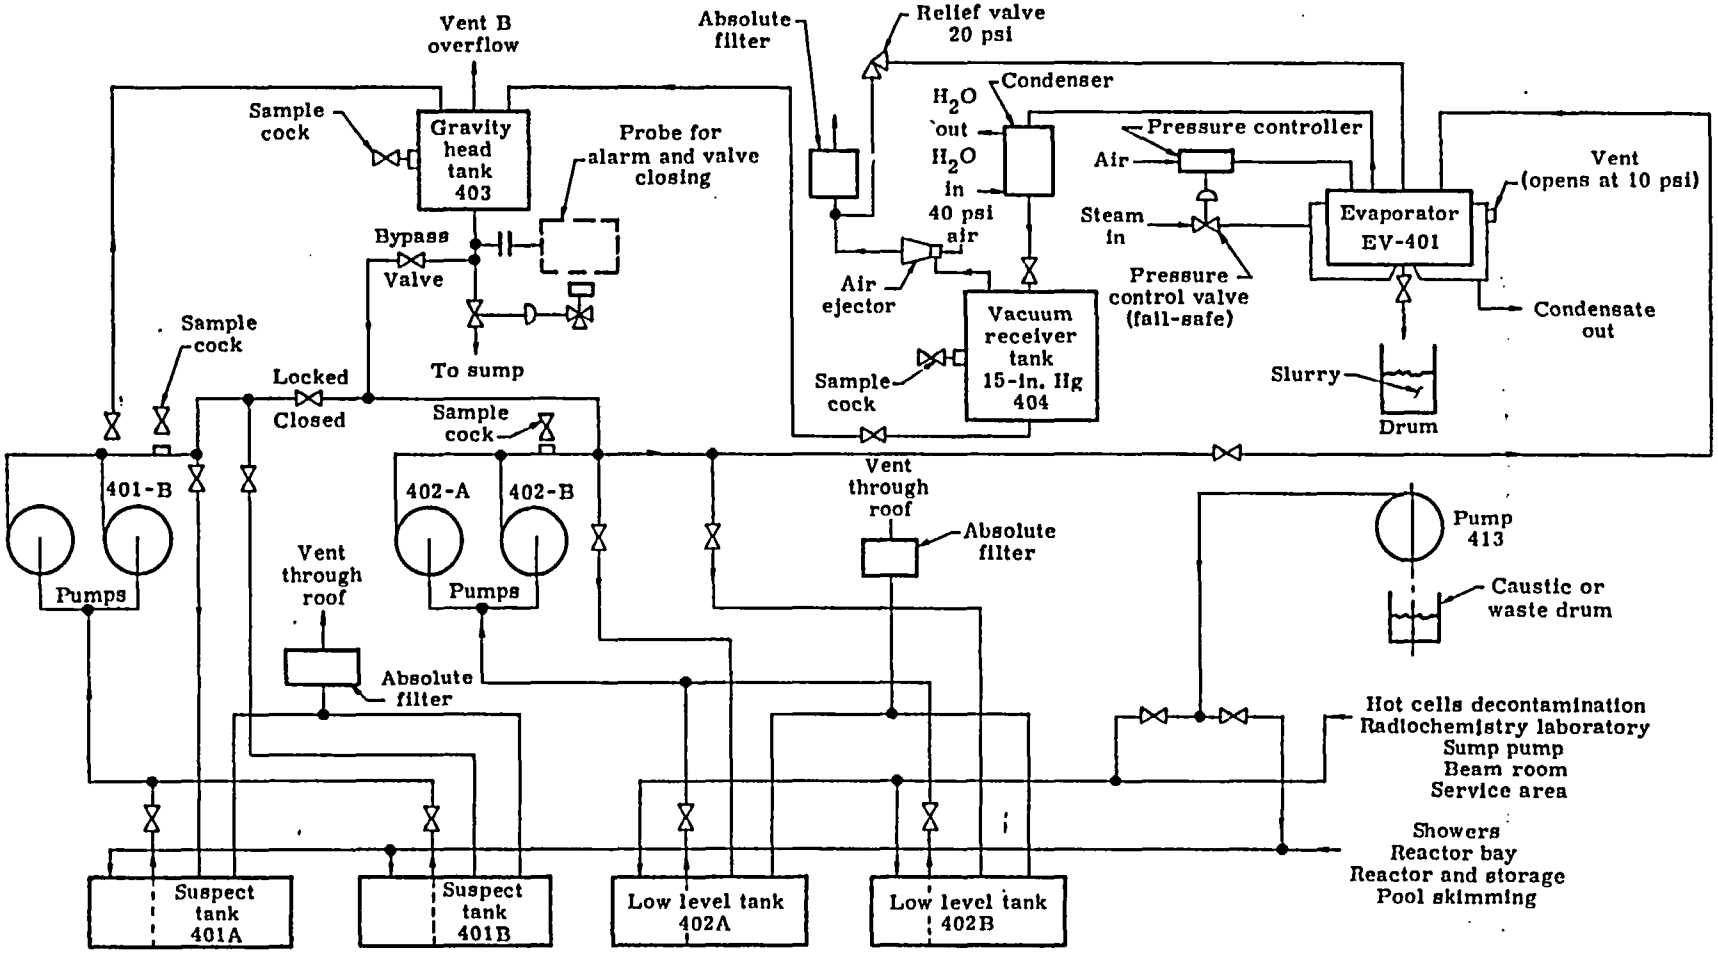

Figure 7.2 Waste Treatment Plant

lead to a "suspect" waste system and originate from such places as the change room showers, reactor area and the personnel decontamination sink in the change room. Each system may be terminated in either of two 3000-gallon underground tanks. When one tank in one system is full, the other tank in the same system may receive drainage.

There are two pumps for each system: one in each system operates when required, with the second used as a standby. When a tank is full, the contents are mixed by circulation through the pump and back to the tank. A sample is then taken from the sampling cock on the pressure side of the pump and an analysis made for radioactivity content. If the activity concentration is below the maximum permissible level for release, the contents of the tank are pumped out for disposal directly to the stream. If the activity concentration is above the permissible level, the contents of the tank are either diluted or pumped to the evaporator.

Following evaporation, the sludge is drained to drums which are shipped offsite for ultimate disposal as mentioned above. The water vapor from the evaporator passes through a heat exchanger-type condenser, and the condensate flows into the 100 gallon vacuum receiver tank and is then transferred to the 1000 gallon gravity head tank where it is analyzed for activity concentration by Pennsylvania State University Health Physics representatives. If the activity is within disposal limits it can

be dumped directly into the Meeker Run, 1500 feet from the facility, via 4 inch plastic pipe. If the activity is too high, it can be again put through the evaporator. Active sludge is drained from the evaporator through a 3-inch valve and pipe into a 55-gallon drum which is preloaded with Flor-co. Figure 7.3 is a sketch of the evaporator and preloaded drum system.

A station has been provided for the addition of caustic to any storage tank for acid neutralization. This station may also be used for the transfer of radioactive waste solutions from other laboratories to one of the storage tanks.

Each group of two storage tanks is vented above roof level through absolute type filters.

The system has been designed to be flexible. The following operations are possible:

(1) The contents of any storage tank can be pumped to the evaporator.

(2) The contents of any storage tank can be pumped to the gravity head tank.

(3) The contents of any storage tank can be pumped to any other storage tank.

(4) The contents of the gravity head tank can be routed to any storage tank.

A complete facility for laundering potentially contaminated clothing is also included in the building housing the liquid waste treatment plant. The effluent from the laundry

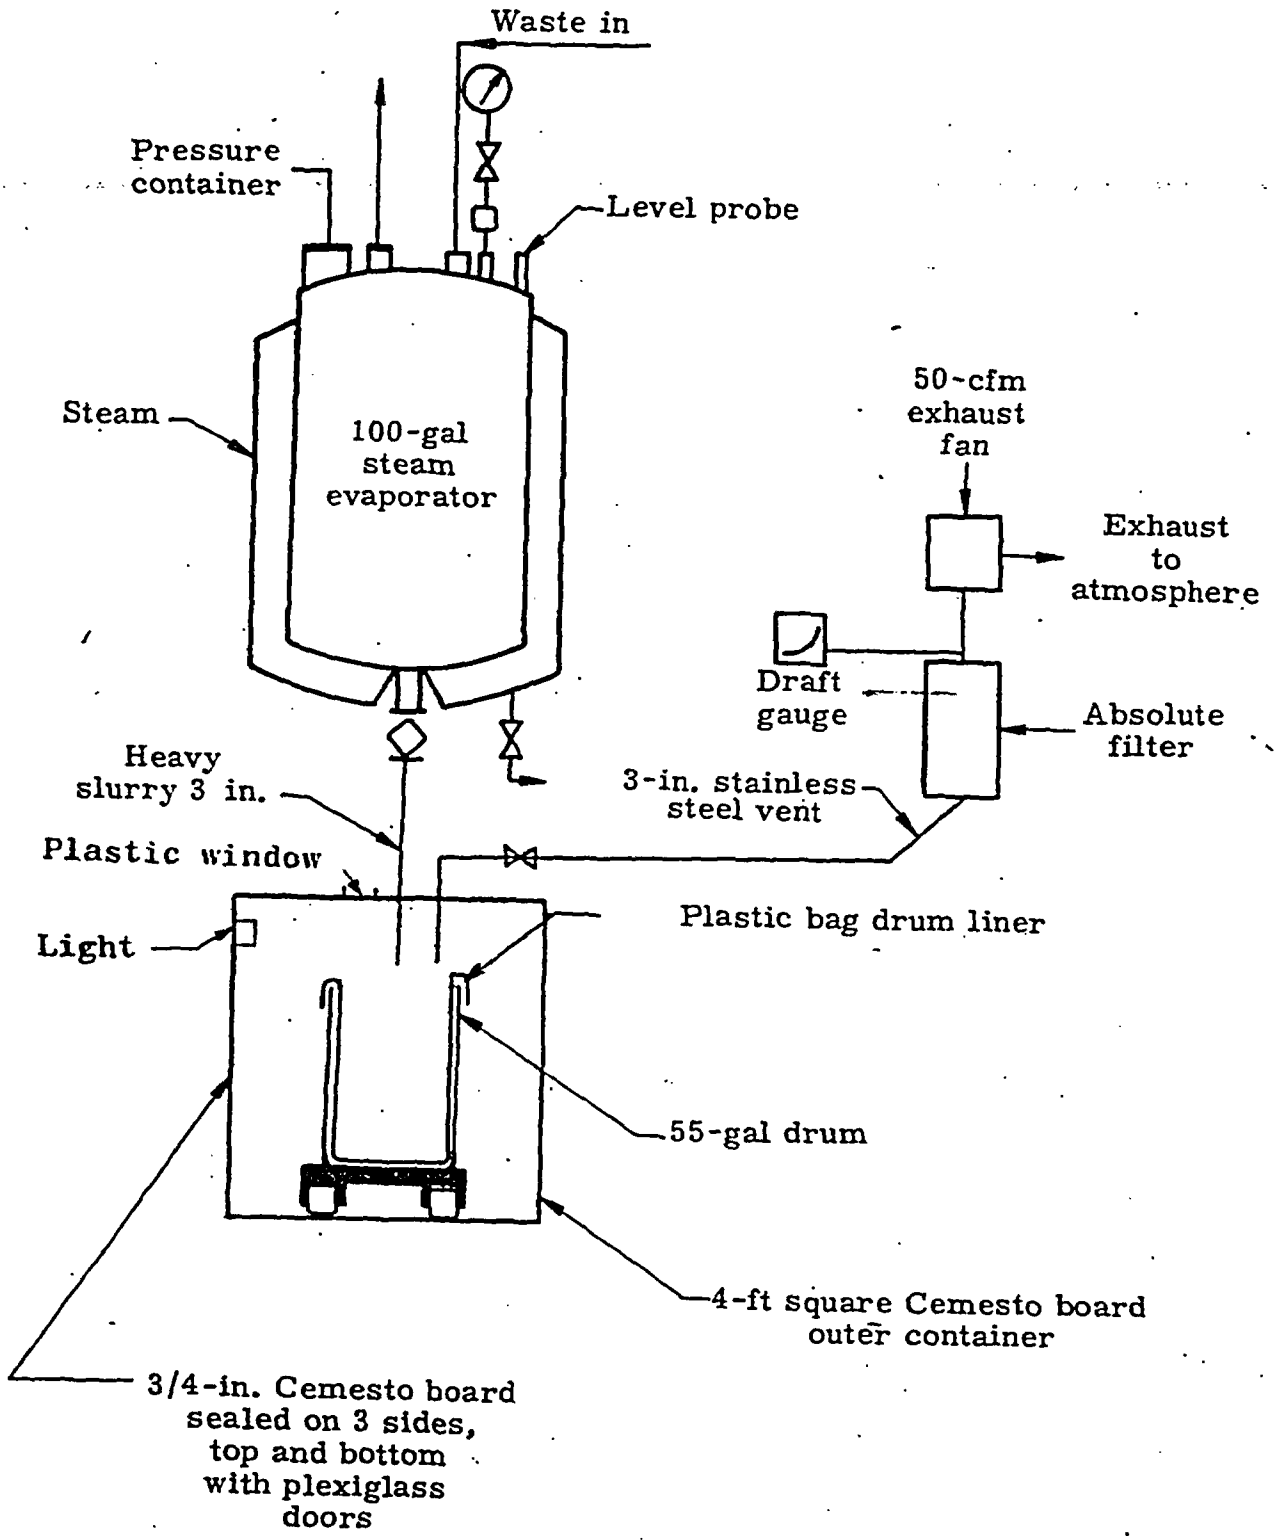

Figure 7.3 Waste Treatment--Sludge Removal

facility drains to the waste storage tank. Under normal operations, this facility is not utilized. The normal procedure is described in Paragraph 10.8.3.

7.1.3 Gaseous System

No radioactive gases or vapors are present in the Strontium-90 process. There is therefore no problem in disposal of gaseous wastes.

Airborne radioactive particulate matter, on the other hand, poses a serious problem. The solution to this problem is achieved through the principle of, and design for, multiple containment. This system includes a barrier of multiple absolute filters in series through which the air must pass before discharge to the stack. The airborne radioactive wastes are collected on filters, and the filter assembly disposed of when the collected particles are sufficient to significantly impair the flow, or the radiation level of the filter is sufficient to dictate replacement.

7.2 Quantities of Wastes

7.2.1 Solids

The principal sources of solid waste are solidified liquids, used filters, contaminated equipment, and the actual solid wastes from the process box. All solid waste is packaged and put in containers for shipment.

Since used filters and contaminated equipment vary in size and shape, it is usually the volume of the drum rather than activity which dictates the amount placed in each drum.

Most of the activity placed in drums comes from the solid waste products of the pellet-making process. Since this waste is of relatively high activity the amount of this waste per drum is dictated by the activity and not the volume. The Bureau of Explosives has approved shipment of drums containing up to 100 curies each. Up to 500 drums can be stored adequately in the waste storage building.

Shipments of waste offsite for burial are at about two-month intervals. Each shipment is 1000-3000 curies, or about 125 drums. These figures are for 10,000 curie batches. The new 25,000 curie batches precipitated will result in more waste but the increase is not anticipated to be large.

7.2.2 Liquids

As mentioned above, the high level liquid wastes from the process are directly converted to solids and shipped as solid waste. Each 10,000 curie batch produces 12 to 20 liters of liquid waste about 40 liters are placed in each drum.

The larger quantity of low level liquid wastes is processed in the waste disposal plant. In the past, the suspect system (very low activity) has collected about 1500 gal/month to be processed. Most of this was diluted with water and discharged to the streams. The low level system has collected about 1000 gal/month. Some of this was run through the vacuum evaporator system and the low level condensate discharged to the streams. The residual liquid was converted to a solid and shipped offsite. The solidified liquid drums are included in the above solid waste quantities.

CHAPTER 8

UTILITIES AND SERVICES

8.1 Introduction

This section covers the normal and emergency utilities and services that are installed at the Quehanna facility. In any radioactive installation it is necessary that provisions be made to supply adequate emergency facilities that will be able to operate critical equipment in the event of a power failure, etc.

8.2 Electricity

8.2.1 Source

Electric power is supplied to the Quehanna Facility by the Pennsylvania Electric Corporation that has a large generating station at Shawville, about 12 miles away. A 13,200-volt power line leads to a substation consisting of two 500-kva, 13,200-volt, 480/277-volt transformers. One of these transformers supplies control and instrument power for the Hot Laboratory and Reactor building sections. The second 500 kva transformer services all heavy electrical motors and equipment in order to control power surges. There are automatic switch-over provisions so that in case either transformer fails the other unit can carry the load. This provision ensures the availability of at least one transformer with power to operate the essential ventilating equipment in the hot cell area. The 440-volt power input is reduced to 208/120-volt service as required for lighting and other services throughout the Radio-isotopes Pilot Plant.

8.2.2 Emergency Power

In the facility, the main emergency power system consists of a generator rated as follows: 43.75-kva, 35-kw, 0.8 pf, 227/480-volt, 3-phase, 4-wire, 60-cycle. The generator is driven by a propane gas-fueled engine delivering a rated output of 81.5 hp at a speed of 1800 rpm. The propane is obtained from the building gas system. An automatic transfer panel transfers the load from the normal source to the emergency source when the normal line voltage fails below 85% and returns the load to normal when all normal line voltages have been restored to 95% or more. Time delay relays are incorporated in the transfer switch to permit the emergency unit to reach rated voltage and speed before the transfer is effected. This takes approximately 10 seconds. When normal power is again available, the system must remain at steady state on the normal bus for 15 minutes before the critical load is automatically transferred from emergency to normal power. The automatic transfer switch is electrically and mechanically interlocked so that there is no feedback from the normal bus to the emergency generator, or vice-versa. Full relay protection guards against phase failure. A built-in test switch to simulate power failure is provided for maintenance checks and testing. A four-position control switch on the control panel permits selection of four operating positions marked STOP, HANDCRANK, TEST and AUTOMATIC.

During a power failure, it is necessary to provide emergency lighting, instrumentation, heating and ventilation for the hot cells. Emergency lighting is supplied in most rooms in the building, and consists mainly of one fluorescent fixture per room. In the hot cells, 50% emergency lighting is provided so that an experiment which is at a critical stage when the normal power fails may continue.

It is necessary to keep the hot cells and process boxes at a negative air pressure with respect to the surrounding areas at all times to prevent leakage of contaminated air into these areas. The following equipment is therefore connected to the emergency power supply:

(1) Exhaust fans E-4 to E-10 and E-13 and E-14
(2) Instrument air compressor (fan controls)
(3) The pneumatic electric switches which cause E-4 to operate in case of an exhaust fan failure
(4) Constant air monitor (CAM)
(5) Remote area radiation monitors (RAM)
(6) Model 8 manipulators
(7) Emergency lighting
(8) Instrumentation power panel

It may be seen that failure of both the normal and emergency power supplies, while most improbable, could cause a potential hazard so emergency exit lights are fed by an independent battery unit. When the normal power is restored, the

emergency exit lights are automatically returned to the normal power circuits.

The entire fire alarm system will operate from the normal power bus. In case of a power failure, the system will automatically switch over to a 24-volt d-c supply obtained from storage batteries. Trickle chargers ensure that all batteries are fully charged when not in use.

8.3 Water Supply

8.3.1 General

Water is provided to the facility from a dam on Meeker Run, upstream from the waste disposal discharge point. A float control in the facility reservoir controls the 100-gpm submersible pump located in the Meeker Run Dam. The surface storage reservoir (see Figure 8.1), covered by an aluminum structure, holds not less than 135,000 gallons of usable water when the surface is not frozen. The domestic water suction line removes water from a higher elevation in the reservoir than the fire protection suction line so that, in case of a water drawdown, there will always be 50,000 gallons of water available for fire protection.

These sources provide water for the following general services: hot and cold sanitary water, steam, process cooling water at 50°F, closed loop process water, and hot process water at 180°F. In addition to these standard services, deionized water is available for filling the source storage pool as well as for any other chemical uses that may be required.

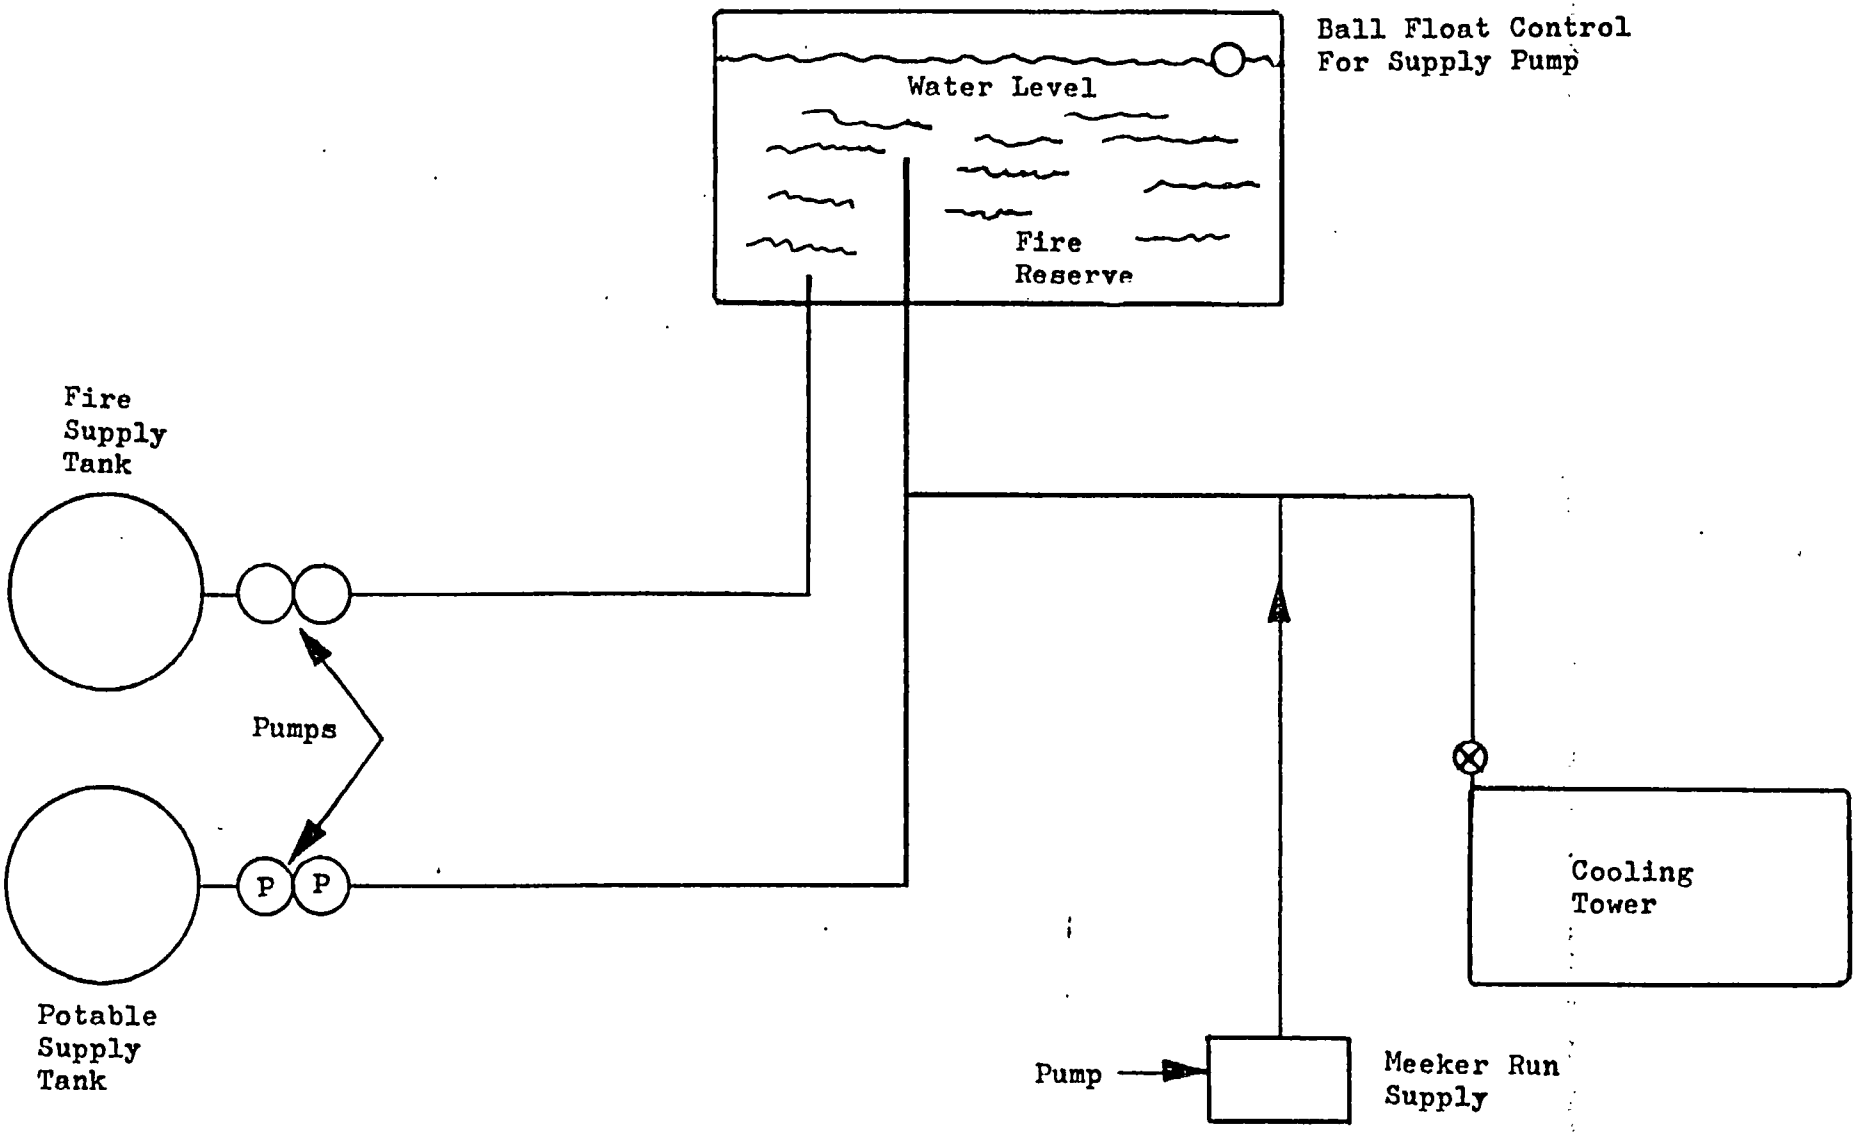

Figure 8.1 Storage Reservoir System

8.3.2 Storage Pool Supply

A deionizing system, installed primarily for the purpose of providing water for the reactor pool, provides deionized water in quite large quantities and ensures a sufficient amount for maintaining the level in the storage pool, even if a leak should develop. The rated capacity of this system is approximately 140,000 gal/day. Figure 8.2 is a block diagram of the system. The storage pool recirculation system is shown in Figure 8.3.

8.3.3 Water for Fire Protection

Three fire hydrants are located outside of the building. The first is approximately 60 feet from the northeast corner of the building, the second about 100 feet from the northwest corner, and the third, a pumper hydrant, on the south side of the building. Each unit is enclosed in a hydrant and hose-reel house which contains 200 feet of 2 1/2 - inch hose and 300 feet of 1 1/2 - inch hose which is sufficiently long to reach any section of the building.

An electrically driven pressure pump on the fire protection pumping system starts at 95 psig and stops at 100 psig and will supply 500 gpm at 100 psig. A booster pump cuts in if the pressure in the fire lines drops to 85 psig and cuts out again when the pressure reaches 110 psig. In case of an electric power failure, a propane-fueled engine-driven pump

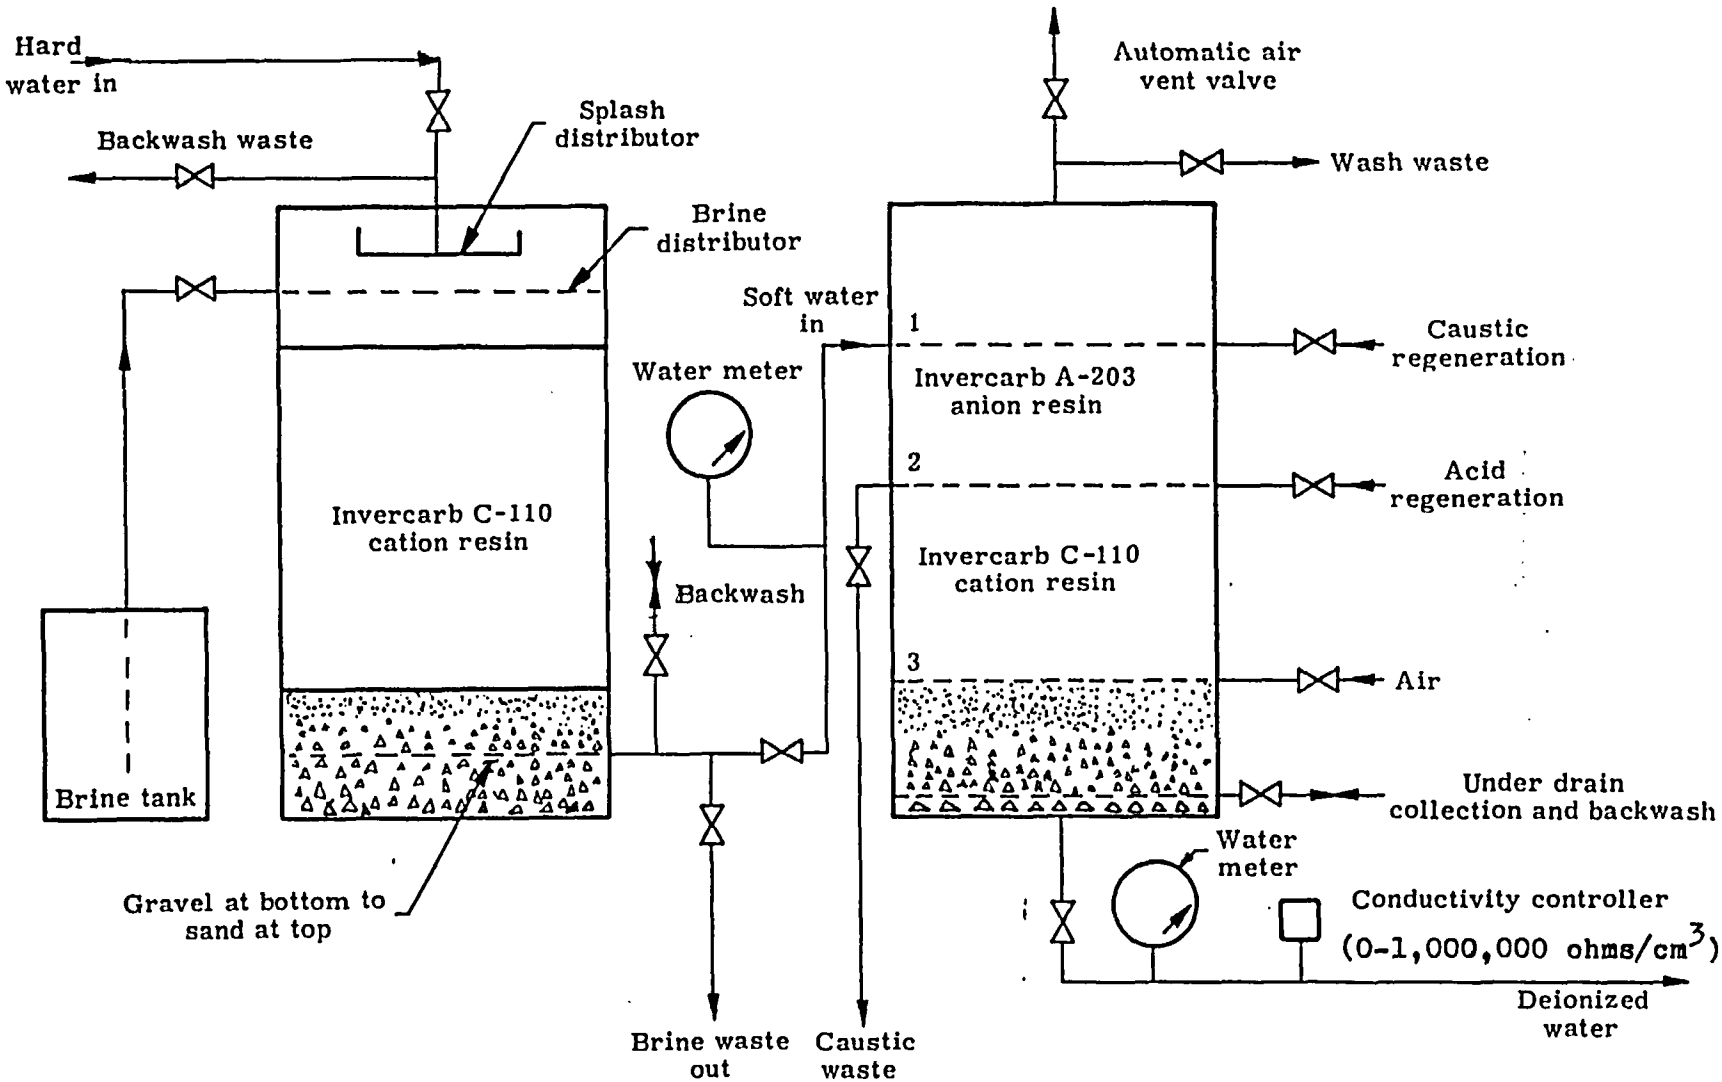

Fig. 8.2 Pool Water Supply System

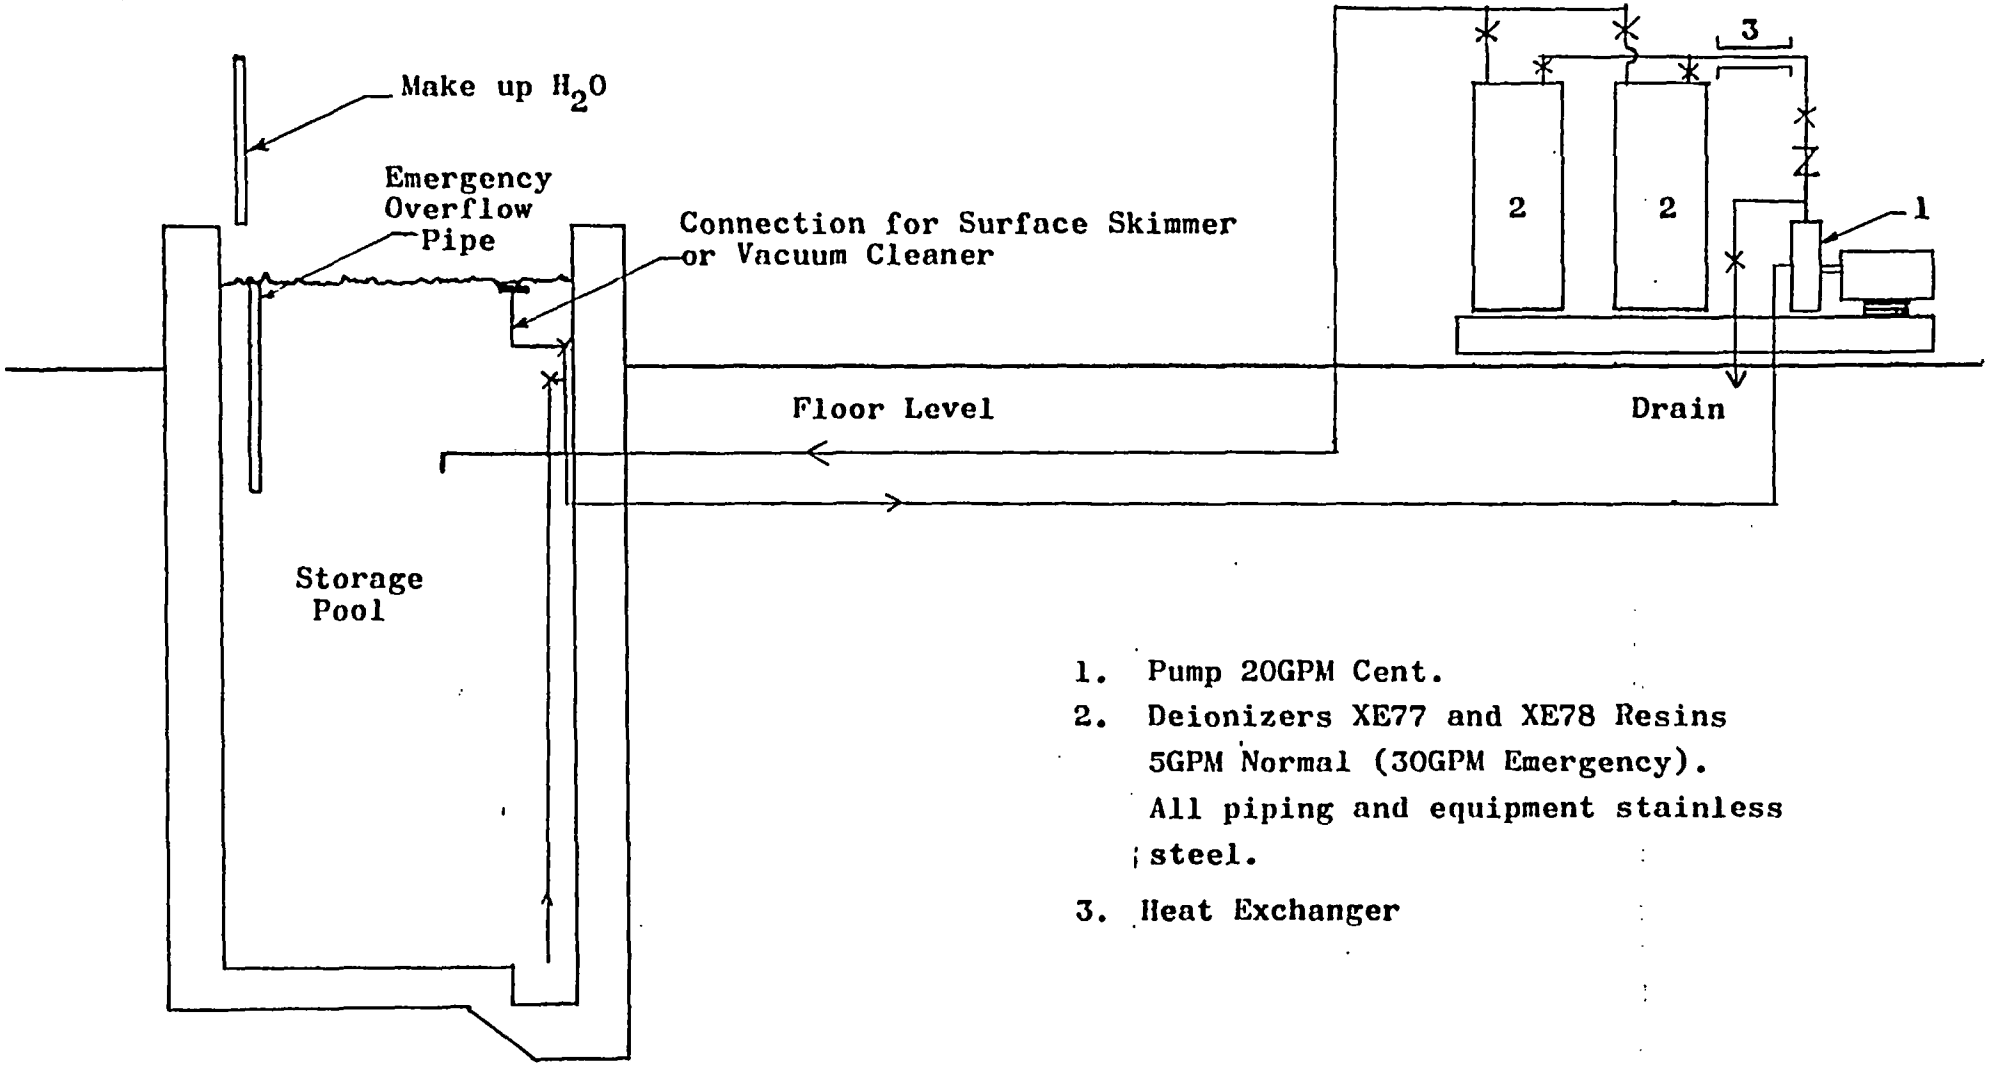

Fig. 8.3 Storage Pool Recirculation System

will cut in automatically when the water pressure drops to 75 psig; however, the pump must be stopped manually.

8.4 Services

The Quehanna Facility is equipped to provide the following services:

(1) Compressed air at 125 psig obtained from an air compressor located in the machanical equipment room.

(2) Propane gas for general distribution supplied by a 1600 gallon tank located on the north side of the facility.

(3) Fuel oil for the boiler and other equipment obtained from a 15,000 gallon underground tank near the propane tank.

(4) Steam provided by the boiler in the mechanical equipment room.

(5) Plant sewerage facilities with a 2,500 gallon septic tank located underground outside the north fence.

CHAPTER 9

DESCRIPTION OF EQUIPMENT

The equipment used in a facility which processes radioactive material must be adequate to protect health and to minimize danger to life and property. This chapter of the report describes the equipment used at the Quehanna Facility. There are three main categories to be considered here; containers, devices and instruments.

9.1 Containers

9.1.1 General Description

Anything that functions to retain radioactive material and/or serves as a barrier against the dispersal of contamination may be classified as a container. Included in this category are transport storage containers, work enclosures and product vessels.

9.1.2 Transport Containers

9.1.2.1 HAPO Shipping Casks

Purified strontium-90 feed material is shipped to the Quehanna site from the Hanford Works in special casks (see Figure 9.1) designed and built for this purpose. Upon arrival at Quehanna, the cask is transferred into the isolation room of Cell 4. There are two sizes of casks used, HAPO-I and HAPO-II.

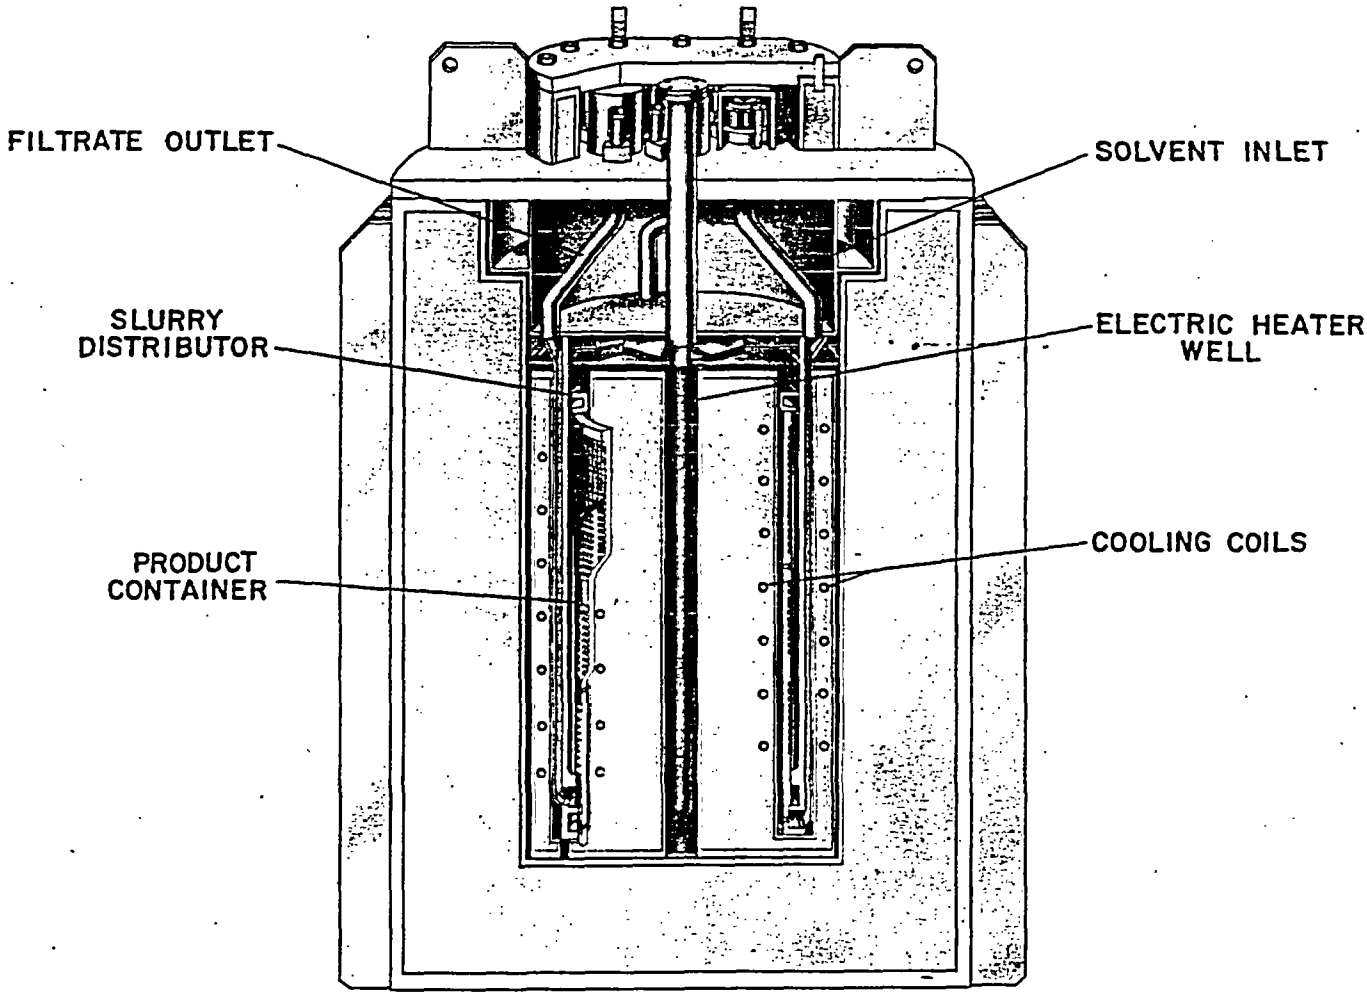

Figure 9.1 HAPO Cask

HAPO-I, the larger of the two sizes of casks, has a capacity of about 500 kilocuries of strontium-90 plus the attendant impurities. Most of the shipments to Quehanna will be made in the HAPO-I casks. The design and accident analysis for both casks are found in reports issued by General Electric Company, Hanford Atomic Products Operation (HW 77963).

HAPO-II, the smaller of the two sizes of casks, has a capacity of about 170 kilocuries of strontium-90 plus the attendant impurities.

9.1.2.2 HAPO Cask Cupola

The cupola (Figure 9.2) is fitted to the top of the HAPO shipping cask before the removal of the strontium fuel is started. Although the cupolas used do not actually hold any strontium fuel, they do serve as protective barriers to dispersal of contaminants during the dissolution procedure. Since it is made of transparent polyvinylchloride, the fittings for the feed solution, etc., may be connected while the cupola is on the cask by using the glove ports and tool port. The procedure for connection of the cupola is described in Paragraph 3.2.2.

After each cask is unloaded, the cupola is bagged and put into a waste drum for disposal. Thus each cask has a clean cupola and no decontamination of the cupola is required.

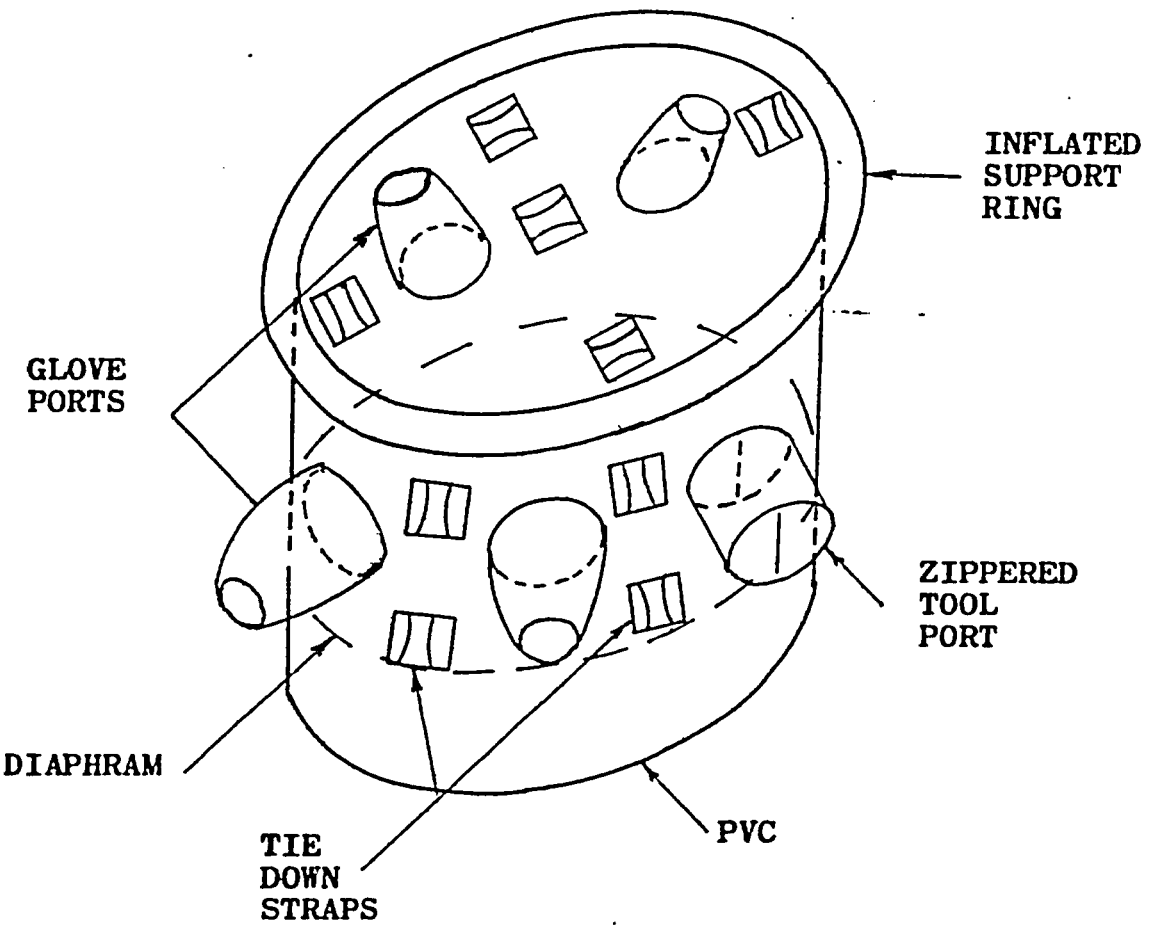

Figure 9.2 Cask Cupola

9.1.2.3 Capsule Transfer Cask

A shielded cask is used to move capsules from the Cell 5 storage to the storage pool. The description of the procedure for transfer is found in Section 3.4.

A typical cask is shown in Figure 9.3. It has 3 inches of lead shielding and is designed for transfer of one capsule at a time. A half-inch steel pin locks the cover in place and serves as a radial support in the event the cask is dropped. Any cask used will be sufficiently shielded for the safe transfer of capsules from Cell 5 to the storage pool.

9.1.2.4 Transfer Box

The transfer box is used to transport small amounts of solid waste and equipment from the process box of Cell 4 to the waste bag-out station in Cell 3. The transfer is made by using the Stationary Overhead Transfer System (SOTS).

Since the box is only used within the confines of the cells and SOTS, no independent shielding is required. The box is made of fire-retardent plywood which is approved by the Underwriters Laboratories, Inc. If equipment larger than this box has to be moved from Cell 4, a new box is made out of fire-retardent plywood or other suitable material.

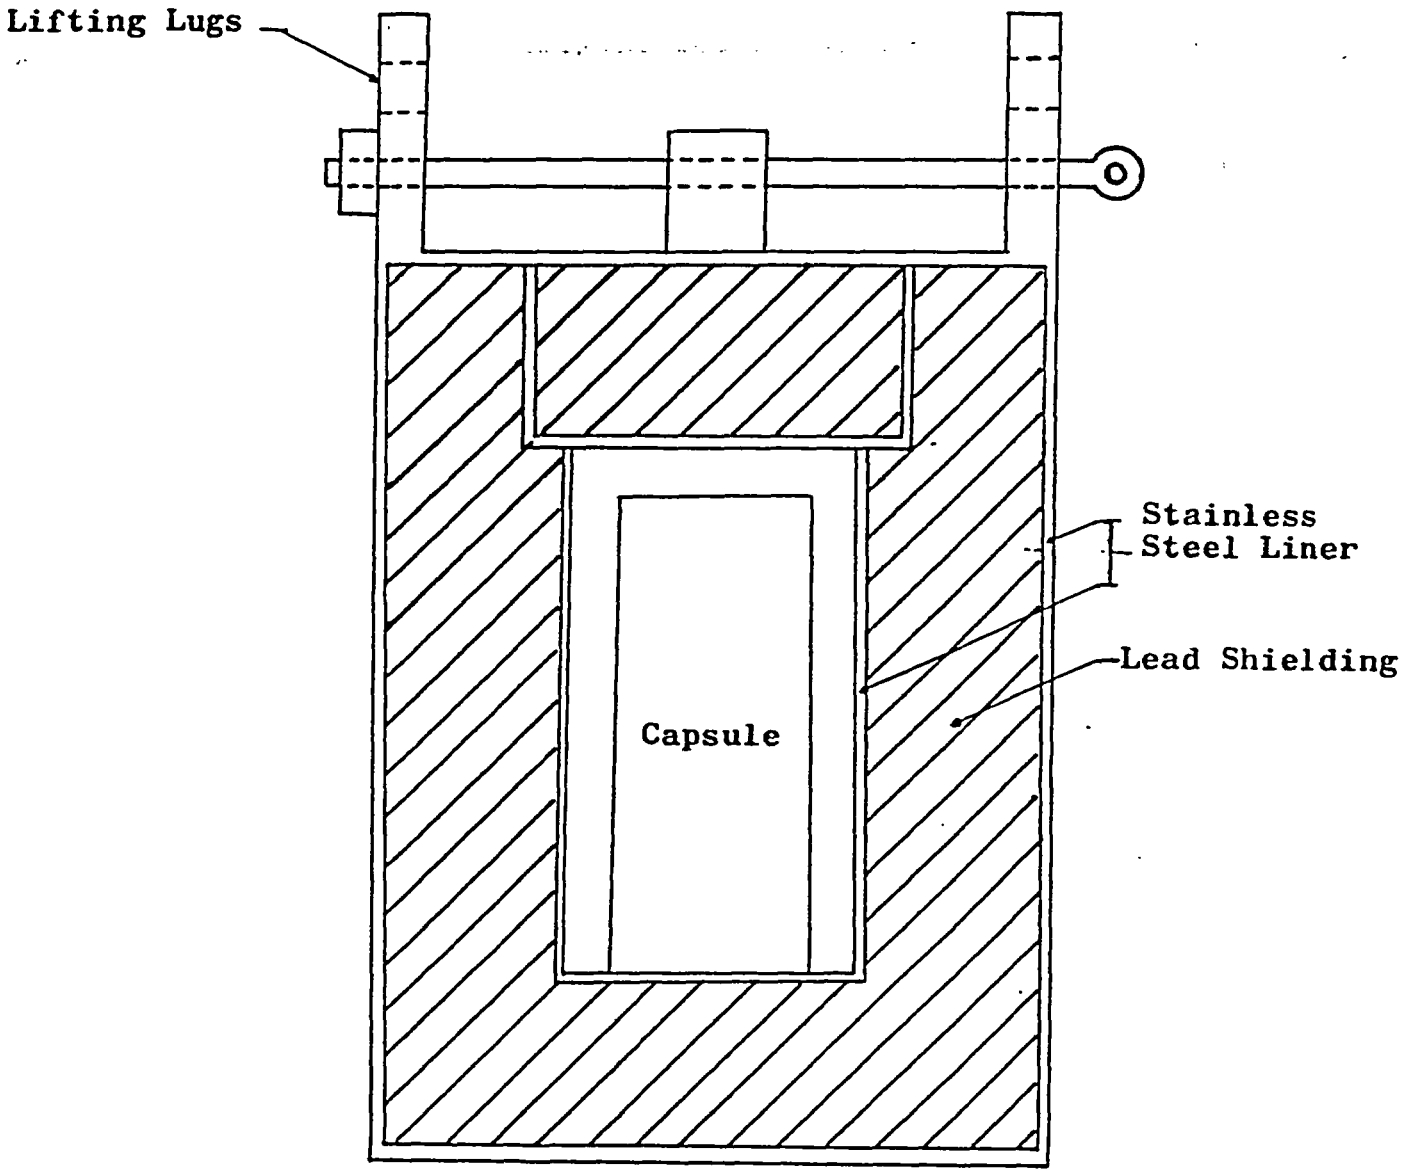

Figure 9.3 Transfer Cask

9.1.3 Storage Containers

9.1.3.1 Storage Pool

Figure 5.1 shows the location of the storage pool in the service area. Capsules are to be stored in the pool, which provides cooling. The pool is 8 feet wide, 10 feet long and 16 feet deep. Its reinforced concrete walls extend 3 feet above the service area floor. The pool is equipped with an expanded metal cover which can be locked in place. The pool is spanned by a bridge which runs on tracks mounted lengthwise atop each 10 foot wall. The bridge is positioned by hand and is used as a platform when samples are moved underwater through the use of long handling tools. The cask used to transfer the capsules (see Paragraph 9.1.2.3) is handled by the service area crane and lowered into the pool, where the capsules are removed for storage. The cask is then lifted above water level, drained, surveyed by Health Physics and removed for further use.

The storage pool is filled from the pool water supply system as described in Section 8.4 of this report. An overflow pipe which terminates one foot below the top of the pool wall leads to the suspect waste system which has a high-level alarm. Paragraph 7.1.2 describes the suspect waste system. The water in the pool passes continuously through a purification system. It is circulated at a nominal flow rate of 20 gpm from a sump sunk below the pool floor level. Then it

goes through a single pump and one of a pair of deionizer tanks and then back to the pool where it is released about five feet below the top of the pool wall. A heat exchanger is added to the system when there are more than 1,000,000 curies stored.

Each of the deionizer tanks contains a removable cartridge made up of mixed anion and cation resins. No attempt is made to regenerate the resins; once then become exhausted, the spent cartridge is removed and replaced with a fresh one. The effluent from the deionizer normally contains less than 1.0 ppm total solids. A portable conductivity meter makes it possible to determine when the resins are exhausted. The deionizer units are located in the mechanical equipment room and are surrounded on 3 sides by a concrete block wall. The fourth side of the enclosure is the outside wall of the building. It is not expected that the deionizers will become sufficiently radioactive to require additional shielding; however, under emergency conditions, a shielded drum would be required for disposal of the resin cartridges.

Processed Sr-90 fuel is to be stored in the form of pellets and powder in double encapsulation, each container being separately welded and leak checked.-

9.1.3.2 Waste Containers

All solid wastes, including equipment, solidified liquid, used filters, etc., are placed in containers for shipment for burial offsite . The loading procedure is given

in paragraph 7.1.1. The containers normally used are standard 55-gallon steel drums. Nested in them are 30-gallon steel drums with the space filled with concrete for shielding. The resulting concrete shield is normally sufficient to lower the radiation level to the specified maximum of 200 mr/hr at the surface, but occasionally additional shielding is required. The drums are approved by the Bureau of Explosives.

9.1.3.3 Cell 5 Fuel Storage

The encapsulated fuel is stored in a chamber which has 8 inches of lead shielding. The chamber has a remotely operated motorized door. The inner basket, in which the capsules are placed, can hold up to 49 capsules. Cooling air is drawn over the capsules by the normal and auxiliary cell exhaust at least 100 cfm.

9.1.4 Work Enclosures

9.1.4.1 Fume Hoods

There are three standard radioisotope hoods grouped along one wall of the analytical radiochemistry laboratory. There is also a stainless steel laboratory sink and stainless steel-topped work bench. Dimensions of the hoods are: width, 6 feet; depth, 3 feet; height, 4 feet. The hood interiors are fabricated of stainless steel and all working surfaces are ground and polished for easy decontamination. The hood exteriors are of mild steel with a baked enamel finish. Services for air, gas, vacuum and water are provided and are remotely controlled from outside the hoods.

The hoods are of the "airflow" type, containing double-wall end panels to achieve streamlined entrance shapes. A single removable baffle is provided at the rear of the hoods with fixed openings at top and bottom for exhausting air from within the hoods. An automatic air bypass at the top of the sash opening limits the maximum air velocity through the face of the hoods and provides for removing a constant volume of air through the hoods. The exhaust fans for the room draw the exhaust through the hoods and are running at all times. The sash opening is adjusted for safe, efficient operation at a minimum air velocity of 100 linear feet per minute (Lfpm). The maximum velocity attained through the hood opening with the sash lowered is 225 Lfpm. The exhaust system for the fume hoods is described in Paragraph 6.2.3.

9.1.4.2 Analytical Glove Box

The radiochemistry laboratory is also equipped with a glove box of stainless steel with 2 inches of lead shielding. The box sits on a stainless steel-topped bench 25 feet long, 3 feet wide, and 3 feet high, placed along the east concrete wall of the laboratory. An air exhaust hood is suspended from the wall and the ceiling, directly over the bench. After the inlet air is filtered through an absolute-type filter it enters the box and exits through the exhaust hood. The exhaust leads through an absolute-type filter and is rejected to the fume hood exhaust system described above in 9.1.4.1. The analytical glove box is used for millicurie-level analytical work.

9.1.5 Product Vessels

9.1.5.1 Solid Waste Bag-out System

The solid wastes are transferred using SOTS to Cell 3 where they are placed in drums for disposal. The solid waste bag-out system consists mainly of a 10 mil polyethelene drum liner, SOTS, and the waste drum. The drum liner is placed in the drum and the open top of the liner is taped to the SOTS downcomer. Then the solid waste, carried to Cell 3 by SOTS, is lowered into the liner and thus into the drum. When the drum is filled, the liner is necked down, closed with tape and sheared off so that the drum and SOTS are sealed and isolated. The drum is then closed and capped with concrete. By this method, wastes are rarely exposed directly to the atmosphere.

9.1.5.2 Process Box

The process box in Cell 4 is divided into two compartments: 4A and 4B. The walls and top of each is 1/8 inch stainless steel and the floors are made of 1/4 inch stainless steel. The greater part of the processing operations are carried out within this box.

9.2 Devices

9.2.1 Manipulators and Periscope

Standard Model 8 Master-slave manipulators are used in all five cells. The larger cells, Cells 2 and 4, are designed for four manipulators each; the small cells accept two

manipulators each. All four manipulators in Cell 4 operate inside the process box, two in each of 4A and 4B.

Special booting is required for the manipulators in Cell 4. The boots consist of a mounting ring that forms an air-tight seal in a special tube on the wall of the process box, a plastic sleeve covering the entire slave arm and full gauntlet over the slave hand (Figure 9.4). The mounting ring is a unique design employing spring steel and flat springs to permit installation through the manipulator port in the cell wall. When installed, the ring occupies a very small annular space and leaves a clear opening for insertion of the manipulator. The boot sleeve is polyvinylchloride reinforced with dacron mesh or equivalent material. The gauntlet is made of heavy polyvinylchloride or similar radiation resistant material.

9.2.2 Service Area Crane

The service area crane is a 15-ton capacity Detroit unit. It is capable of being maneuvered to any location in the service area or above the cells and will clear the SOTS.

9.2.3 Stationary Overhead Transfer System

The Stationary Overhead Transfer System consists of a series of structures which when assembled form doubly-contained airtight compartments connecting the process box 4A and 4B to the bag-out station in Cell 3.

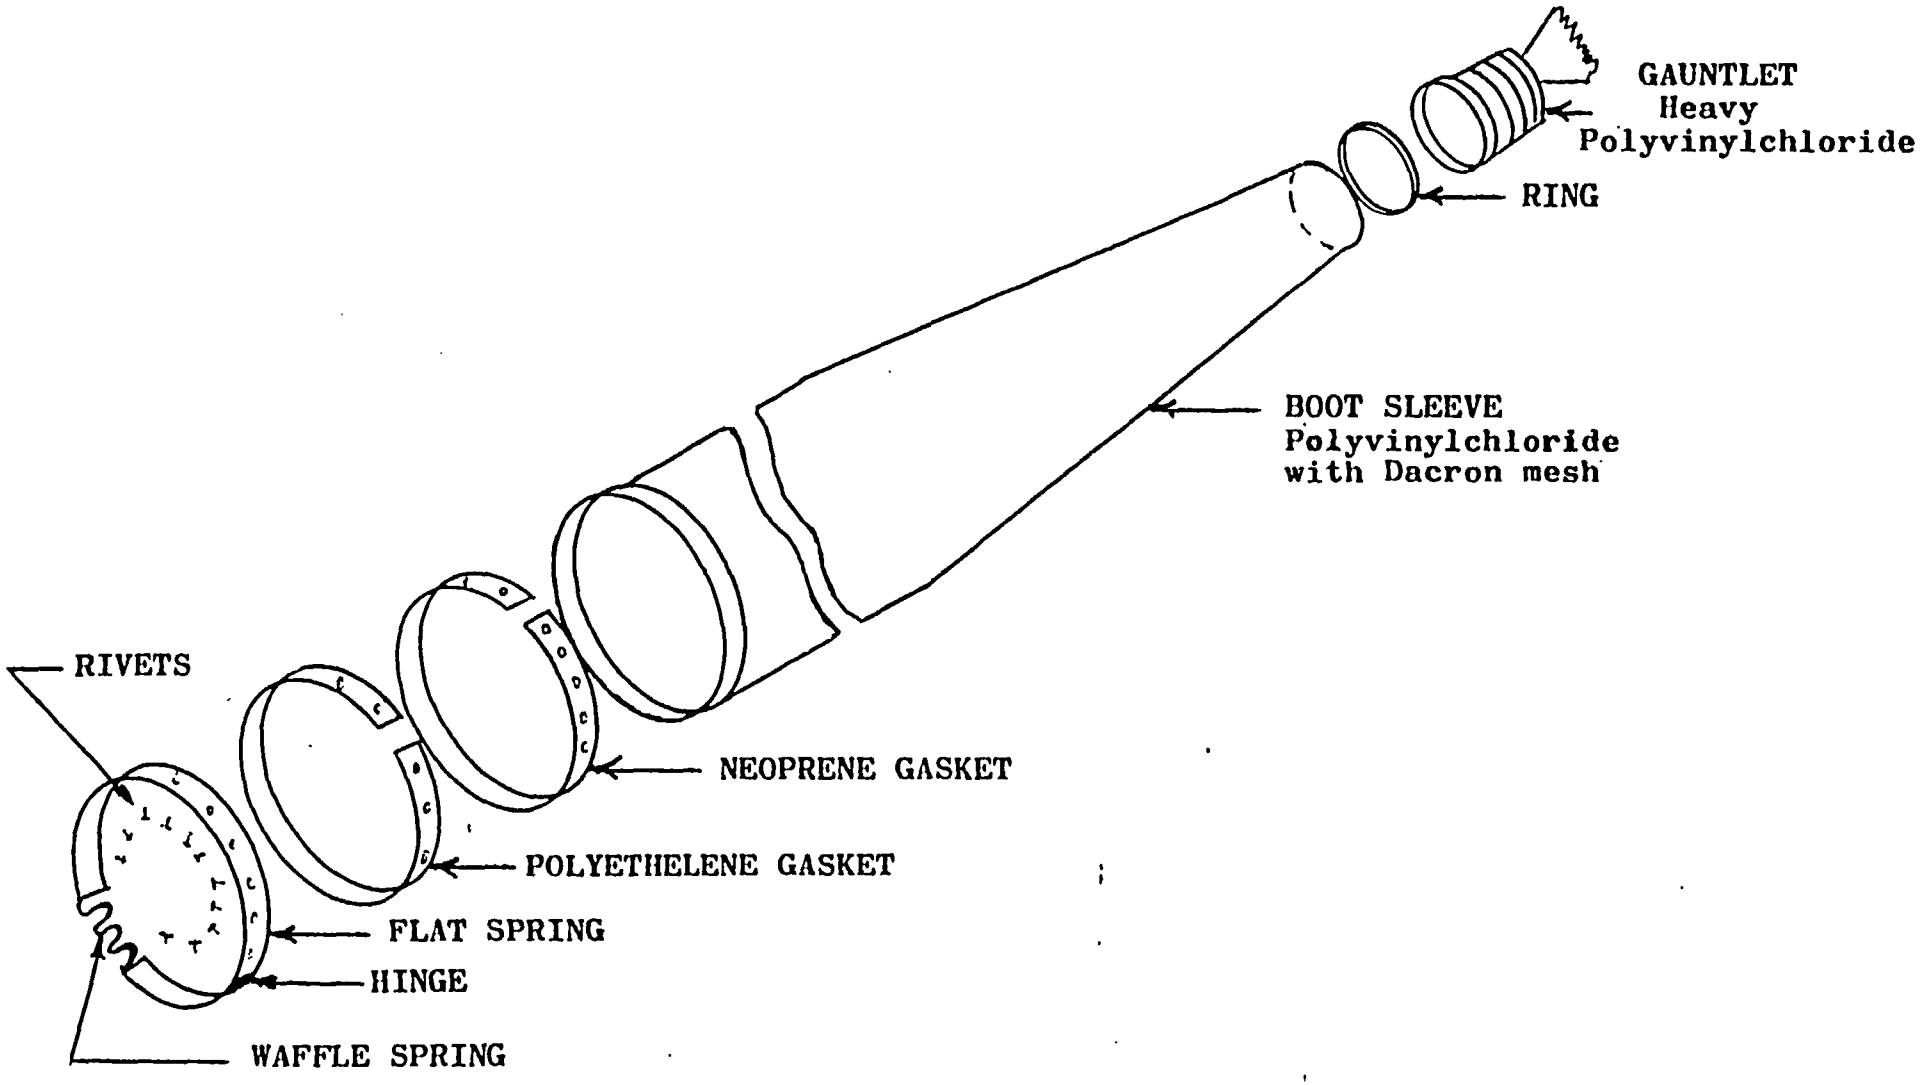

Figure 9.4 Manipulator Boot Assembly

The inner containment unit is approximately 5 ft wide, 7 ft high and 20 ft long and is fabricated of 1/16 inch aluminum. This unit has sealed, bolt-on end plates with windows so that it can be extended in either direction at a later date, and is equipped with a remote operated 2-ton hoist so that material can be moved in or out of Cells 3 and 4. The three doors from process box 4A and 4B and Cell 3 are shielded and motorized (see Figure 9.5).

The secondary containment barrier and main support for the 2-ton hoist is a concrete block wall around the inner barrier approximately 9 ft wide, 7 ft high and 22 ft long. The top has I-beams to support the hoist and is covered with an aluminum leaktight top. Ventilation details are described in Chapter 6. SOTS is equipped with two spray bars which run lengthwise between Cells 3 and 4. These facilitate washdown of the interior. The floor is tilted to provide adequate drainage into a liquid waste disposal container.

9.2.4 Fork Lift Trucks

The fork lift trucks can be used to move the waste drums. One truck is a Clark, propane powered, high-lift model with a capacity of 3,000 pounds. The other is a Raymond Electric with the same capacity.

9.2.5 Pallet Truck

The pallet truck which has been used to transport the HAPO-II casks to and from the isolation room of Cell 4 is an electric powered Automatic Transporter truck with a capacity of 15,000 pounds.

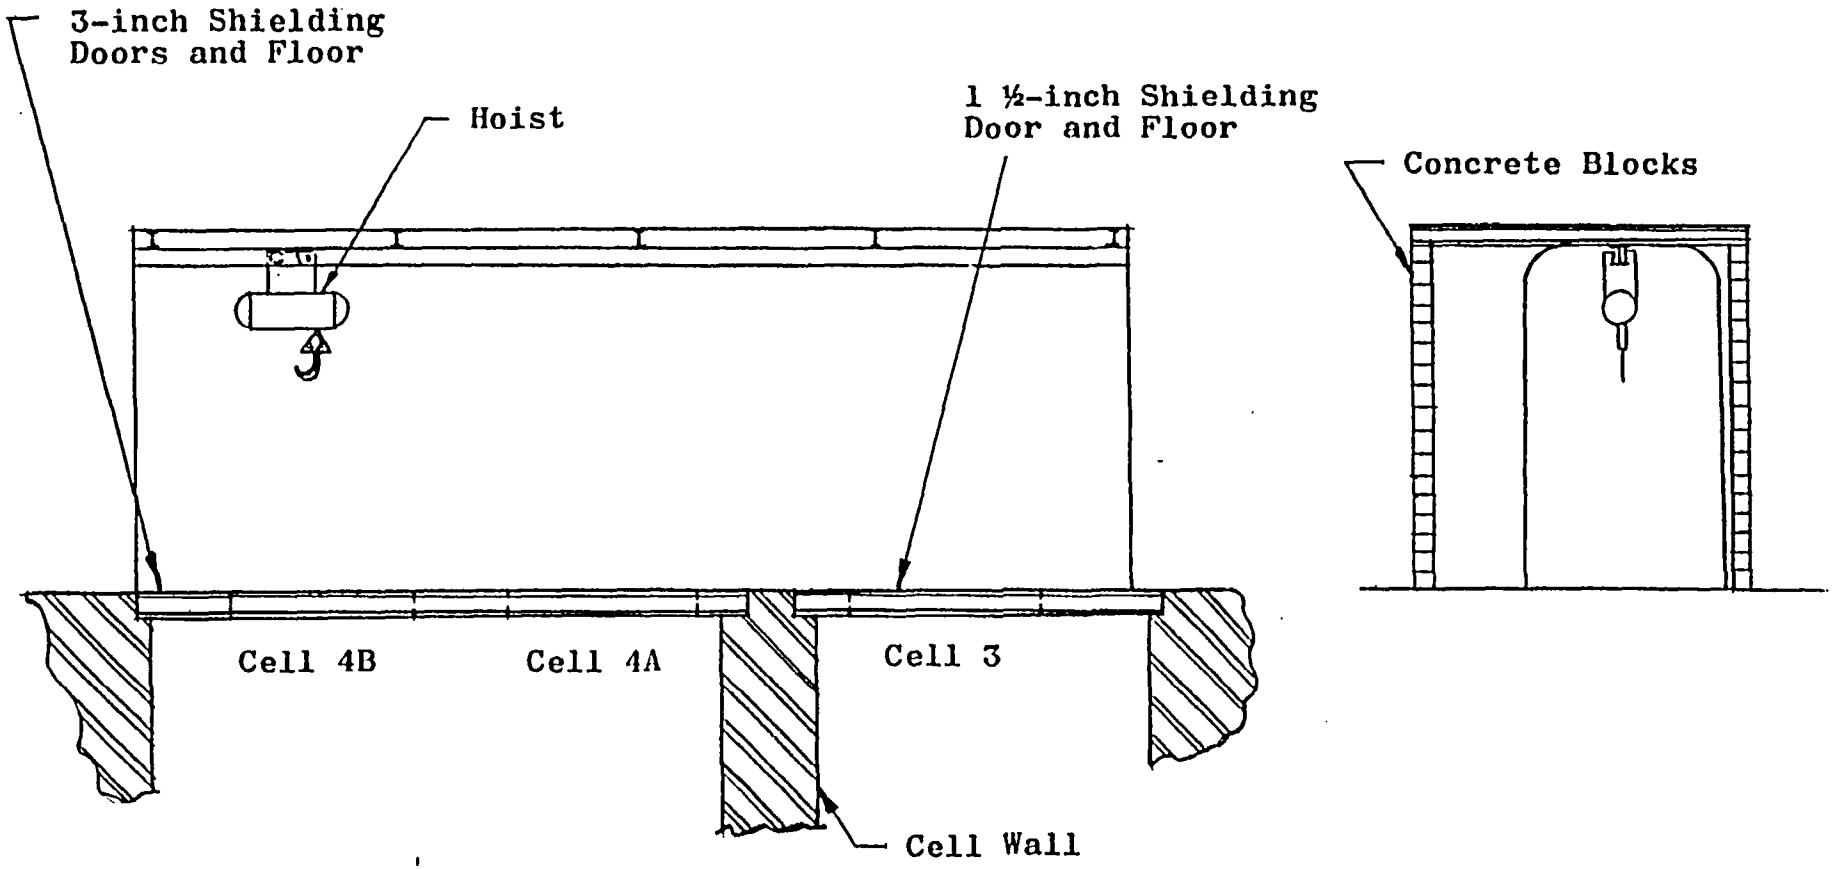

Figure 9.5 Stationary Overhead Transfer System

9.2.6 Flat-bed Truck

The flat-bed truck (see Figure 9.6) is designed to move HAPO-I or HAPO-II casks from outside the building into the isolation room of Cell 4. The four-wheeled, steerable, steel truck is 54 inches wide, 96 inches long and is capable of carrying 40,000 pounds.

9.2.7 Remote Area T.V.

A remote operated television will be installed in isolation room 4. It will be used to monitor the HAPO cask dissolution, read liquid level instruments and observe the sample box and cask cupola. It is a Model ARM 14 R Kin-tel.

9.2.8 Furnace

The Marshall electric furnace used has twelve glo-bars and six thermocouples and is remotely controlled from the operations area. The effective heating volume is 7 inches wide, 13-3/4 inches high and 16 inches long. The upper temperature limit is 1500°C and the furnace is water cooled.

9.2.9 Blender

The blender is used to mix the fuel powder so that an even consistency of powder is available for pellet pressing. The blender may be either a commercial Waring or a Y-type unit.

9.2.10 Pellet Press

The press used is a Modern Hydraulics 250-ton unit with a 12-inch ram and a 6-inch stroke.

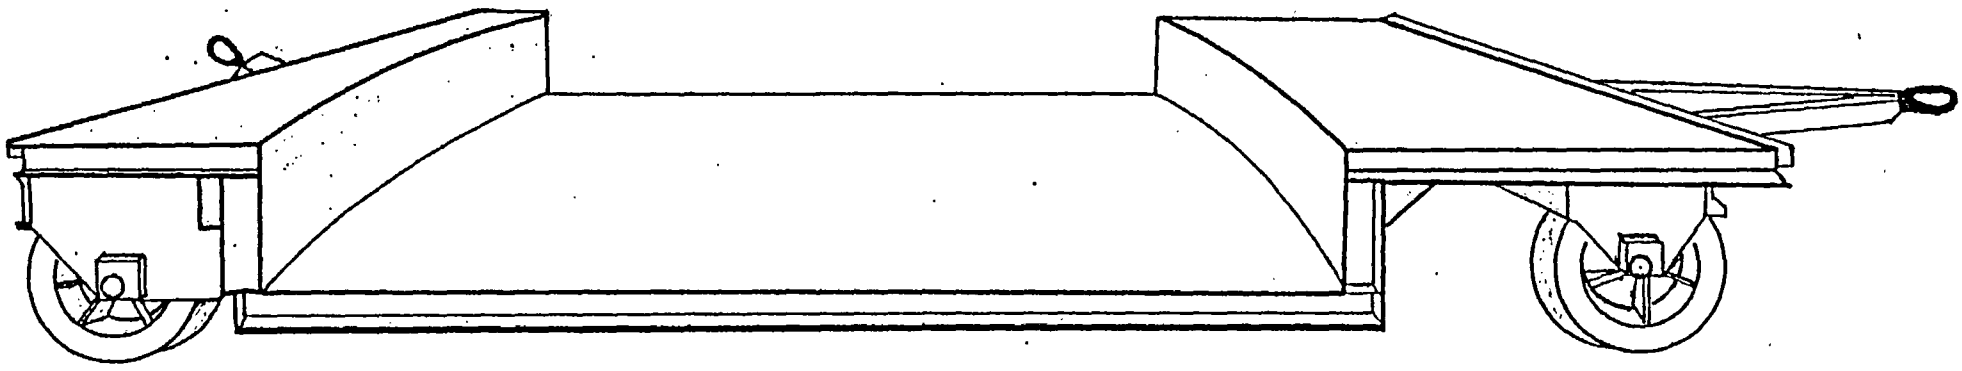

Figure 9.6 Flat-bed Truck for Transporting HAPO Cask

9.2.11 Capsule Welder

The capsule welder is a remote controlled, motorized unit using inert gas in a Heliarc process. The unit is Martin fabricated and is powered by a Harnisohfeger P and H power supply.

9.2.12 Capsule Leak Detector

The capsule leak detector is a Vacuum Electronics Corporation (Veeco) mass spectrometer unit.

9.3 Instrumentation

The following is a typical list of instruments used to control the process:

Use	Qty.	Make & Model No.	Type
Connects tanks and recorder for liquid level measurements	5	Foxboro Model 13A	Differential pressure cell transmitter w/316 S.S. bodies and diaphrams
Records liquid levels of tanks	5	Foxboro Model 5410-S	Liquid level recorder pneumatic single pen
Supplies air to pneumatic system	5	Foxboro IAS-FE	Indicating air set w/fixed pressure reducer and filter
Charts for various ranges on recorder	3	Foxboro Special Scales	Scale variation by separate charts

Use	Qty.	Make & Model No.	Type
Measure air flow	10	Foxboro Standard Model	Rotometer for air flow
Regulates pressure for air ventilation system	2	Foxboro Standard Model	Pressure regulator
Controls Indicating Receiver	1	Foxboro Model 41E	Indicating receiver controller w/high level contacts
Furnace Control	1	Brown	Controller recorder
Hydraulic Press Control	1	Modern Hydraulics	Electric motor, pump and pressure indicator
Welder Control	2	Harnischfeger, P & H	Heliarc, inert atmosphere
Leak Testing	2	Veeco	Mass spectrometer

CHAPTER 10

HEALTH PHYSICS PROGRAM

10.1 Introduction

The radiological safety program for the Martin Radioisotope Pilot Plant has been developed to assure maximum safety. The overall objectives of the program are to protect facility personnel and the general public.

The definition of responsibilities relative to radiological safety is essential to the safe conduct of all operations involving potential radiological hazards. All parties concerned with any activity which may involve a radiological hazard must be cognizant of their obligations. Overall responsibility for radiological safety, as for any other health or safety matter, rests with management and is discharged through management's representatives.

10.2 Health Physics Organization

The Health Physics Group at Quehanna consists of a resident Health Physicist and Health Physics technicians staffed on a level-of-effort-basis. This group is supervised by the Supervisor, Health Physics Section, Baltimore, who reports to the Director of Support Services for the Baltimore complex of the Martin Marietta Corporation.

10.3 Overall Health Physics Responsibility

It is the responsibility of the Health Physics Group to provide the radiological protection program required to support operational activities conducted at the Martin Radio-isotope Pilot Plant.

10.3.1 Supervisor, Health Physics Section - Baltimore

The Supervisor, Health Physics Section is responsible for continuous surveillance of the performance of the Health Physics Group at the Quehanna Pilot Plant. He routinely visits the site to personally evaluate conditions. In addition, he investigates any anomalies in the weekly summaries or any unresolved condition mentioned in any special incident report provided by the resident Health Physicist. He discusses these special situations by phone with persons at the site who can effect correction. If deemed necessary, he makes an immediate trip to the site to attempt to resolve the problem. Furthermore, it is his duty to inform management regarding abnormal situations. He has complete freedom to cross organizational lines and discuss matters pertaining to radiation safety with any person.

10.3.2 Resident Health Physicist

Technical direction of the radiological protection program is the responsibility of the resident Health Physicist. This responsibility includes items such as: development

of safe practice rules; review of daily Health Physics and operations log books; facilities, operations and environmental monitoring; surveillance and documentation of personnel exposures; instrument calibration and calibration source control; decontamination and waste disposal consulation and supervision, radiological safety indoctrination; emergency radiological capability; review of facility and equipment design or modification, furthermore, he submits a weekly written summary of Health Physics activities to the Supervisor, Health Physics Section - Baltimore. This summary contains a detailed resume of radiation and contamination conditions resulting from operations, and is supplemented by special reports made via telephone.

10.3.3 Health Physics Technician

Currently a Health Physics Technician is assigned to support each operating shift. His responsibility includes: conducting and documenting radiation-- contamination surveys; notifying supervision of survey results and personnel exposures; inspecting to see that operations are conducted in accordance with approved practices; recommending protective equipment requirements; notifying and consulting with the resident Health Physicist regarding non-routine operations or conditions; calibrating Health Physics instrumentation.

10.4 Control of Access to Radiation Areas

10.4.1 Radiation Area

The sections of the facility which are included in the radiation area are: Operations Area, Service Area, Hot Cells, Cell Isolation Rooms, Radiochemical Laboratory, Decontamination Room, Storage Area, Fan Room, and the Machine Shop. Normal access to the areas listed above is through the change room complex. All entrances to this area other than through the change room are kept locked at all times, using the lock system described in Paragraph 10.4.3.

10.4.2 High Radiation Areas

Certain hot cells, and isolation rooms are normally high radiation areas. Whenever radiation reaches a level such that a major portion of the body could receive more than 100 mrem/hr, the area is marked as a high radiation area and is suitably restricted. High radiation areas are controlled with a special absolute integrity locking system in lieu of the control device specified in 10CFR20.

10.4.3 Lock System

The lock system used is manufactured by Best Universal Lock Company, Indianapolis, Indiana. This system is utilized at several AEC installations and is designed for maximum security. Significant features which make it suitable for controlling "high radiation" and/or "radiation" areas are:

10.4.3.1 Key blanks are of a special design and are not obtainable by unauthorized personnel, therefore, it is not possible to have a key duplicated without proper authorization.

10.4.3.2 The manufacturer will supply locks, keys, and combinations for keys only upon the written authorization of the person who has been designated to control the system.

10.4.3.3 The hardware is very sturdily constructed.

10.4.3.4 The combinated core of any lock in the system can be changed immediately by the person controlling the system. This makes it possible to restrict access to those persons holding a particular key or to prevent access completely. It also allows immediate renewal of the locking system integrity should any key be last.

10.4.4 Administration of the Locking System

The integrity of the locking system is maintained by the following administrative steps:

10.4.4.1 The authority to procure locks, cores, keys, or combinations is restricted absolutely to the Supervisor, Health Physics Section.

10.4.4.2 Alteration of the system installation or removal of locks, or issuance of keys is done by the resident Health Physicist only under a written order from the Plant Manager. A complete record of key receipts and issuances is kept by the resident Health Physicist. All keys and cores are accounted

for and an audit of keys including a check of the keys in the possession of the users is conducted quarterly by the resident Health Physicist. The results of the inventory are reported to the Plant Manager and the Supervisor, Health Physics Section - Baltimore.

10.4.4.3 Radiation areas are divided into four categories for controlling access:

10.4.4.3.1 Areas where radiatior levels are less than 100 mr/hr - access by facility operation and support personnel.

10.4.4.3.2 Areas where radiation levels are greater than 100 mr/hr but less than 25 r/hr - access by shift supervisor.

10.4.4.3.3 Areas where radiation levels are greater than 25 r/hr - these areas are locked with two separate locks, one of which is controlled by the shift supervisor and one by the Health Physics representative on duty. Both locks must be unlocked in order to gain access.

10.4.4.3.4 Areas requiring special control - access to these areas requires the concurrence of the Plant Manager or the resident Health Physicist with their physical presence.

10.4.5 Radiation Work permit

All activities in "Radiation or High Radiation Areas" are performed in accordance with standard operating procedures. Work performed in these areas requires special authorization in the form of a Radiation Work Permit (RWP).

The RWP is a written instruction sheet that is issued prior to the start of an operation in radiation areas and includes items such as: description of the job, results of the most recent surveys, maximum work time for locations within the area, required protective equipment and personnel monitoring devices, special instructions, approval to start work, signatures of the shift supervisor and the Health Physics representative. The operations supervisor is responsible for initiating the RWP. Health Physics is then notified for pertinent instructions,, preoperational surveys and approval. Once the RWP is in effect, the Health Physics representative provides on-the-job monitoring, as required, depending upon the type of operation and sees that no one enters the work area other than authorized personnel. The RWP becomes void at the conclusion of each job and is returned to the operation Supervisor for filing and retention.

10.4.6 Summary of Operations Requiring Health Physics Monitoring

Survey and control procedures are utilized to effectively limit personnel exposures. Surveys are made to determine external dose rates, the presence or absence of surface contamination and airborne concentrations in work or occupancy areas. Typical operations that require monitoring include: receipt of HAPO cask, HAPO cask installation for dissolution, removal of HAPO cask and preparation of empty cask for

return to Hanford, process Sr-90 feed materials, feed sample analysis, radioactive waste handling and shipment, intercell transfer, storage of encapsulated fuel, generator loading operations, and shipment of fueled generators.

10.5 Description of Survey Techniques

Health Physics conducts daily radiation - contamination surveys in the facility. A variety of instruments are available capable of monitoring all ranges of contamination and/or radiation encountered. Any unusual levels are reported to supervision and proper precautions are taken to reduce personnel exposures. The shift supervisor initiates decontamination procedures, and a resurvey of the area is conducted when decontamination is completed. Additional radiation surveys are performed as required to support operational activities.

The individual conducting the survey wears the required protective clothing and equipment as described in 10.7.4 and personnel monitoring equipment described in 10.6.2 and proceeds to make measurements of external radiation and airborne, loose or fixed contamination. The Health Physics representative provides continuous evaluation of the radiological conditions while the job is in progress.

10.5.1 External Radiation Measurements

The measurement of external radiation levels is performed with portable monitoring instruments. A list of

the instruments available is contained in Table 10.1 including their detection range and specific uses. Portable instruments are frequently checked in the field utilizing a reference source. Malfunctions are reported to the instrument repair technician.

10.5.1.1 Minimum Routine Survey Schedule

Location	Radiation	Contamination
Operating - Shop Area	Weekly	Daily
Service Area	Weekly	Twice Weekly
Cell Faces	Weekly	Weekly
Iso Rooms	Upon Entry	End-of-Operation
Radio Chem. Lab	Weekly	Twice Weekly
Decon Room	Weekly	Weekly
Change Room	-	Daily
Liquid Waste Bldg.	Weekly	Weekly
Waste Storage Bldg.	Weekly	Weekly
Office Areas	-	Weekly
Lunch Room	Twice Weekly	Twice Weekly

10.5.1.2 Posting Areas

All radiation and high radiation areas are posted with the appropriate warning signs. These areas are surveyed periodically in order to update or change the signs depending on conditions.

TABLE 10.1

Type of Instrument	No. Avail.	Radiation Detected	Window Material and Thickness	Sensitivity Range	Use

10.5.2 Fixed Area Radiation Monitoring System

Overlapping high and low level area radiation monitoring systems are installed. The low level system consists of three detector units with ranges from 1 mr/hr to 1 r/hr located in the operating area, service area, and the radiochemistry laboratory. These units are set to alarm above 10 mr/hr and are connected into a central annunciator panel which activates both a horn and light. The two high level units, with ranges from 10 mr/hr to 10 r/hr, are located in the operating and service areas. These units are connected into the building evacuation alarm siren and are set to alarm above 1 r/hr.

10.5.3 Facility Contamination Measurements

Contamination of areas falls into two broad categories; namely, surface and airborne contamination. Surface contamination in turn is classified as fixed and loose. Separate measurements are necessary to fully evaluate the degree of hazard.

10.5.3.1 Monitoring for Surface Contamination

Smears are used for monitoring loose surface contamination. Geiger-Mueller survey meters, are generally used for detecting and measuring fixed contamination.

10.5.3.1.1 Procedure for Monitoring Loose Surface Contamination

A dry porous paper (smear) is wiped over a standard area (approximately 100 cm^2) of surface being monitored. Precautionary measures are employed when smearing areas

where a high degree of contamination is suspected. Used smears are placed in paper smear holders to prevent cross contamination. The smears are monitored for gross contamination with a G. M. count ratemeter unit before they are taken to the counting room for a more refined analysis. Care is exercised in order to avoid contaminating counting equipment.

10.5.3.1.1.1 Counting Smears

Smears are counted for beta-gamma activity utilizing a Geiger tube detector/scaler assembly. The length of count depends upon the activity present on the smear and the counting accuracy required. Most smears are counted for one minute. A diagram indicating location of the smear, instrument reading and contamination level is given to the shift supervisor who initiates decontamination as required. Areas that cannot be immediately decontaminated are marked accordingly and entrance is restricted to authorized personnel wearing the specified protective equipment.

10.5.3.1.2 Procedure for Monitoring Fixed and Loose Surface Contamination. Monitoring for fixed beta-gamma contamination is performed using a G. M. survey meter. The activity indicated is a measure of both fixed and loose surface contamination unless the loose contamination has already been removed. Measurements are made holding the G. M. probe approximately one-half inch above the surface being assayed. The fixed beta-gamma contamination levels are generally expressed in terms of mrad per hour.

10.5.3.2 Monitoring for Particulate Contamination in Air

Continuous air monitors and fixed filter air samplers are used to determine the concentration of airborne radioactivity. Sampling for airborne radioactivity is accomplished by drawing a known volume of air through a filter paper capable of entrapping extremely small particles. The paper used is greater than 99% efficient for particulates greater than 0.3 microns in diameter. The filter paper is then removed from the air sampler or continuous air monitor, scanned for approximate degree of activity, then placed in a gas proportional detector/scaler assembly to precisely measure the degree of radioactivity collected. A calculation is then performed to determine the airborne concentration. This method is capable of detecting less than 1×10^{-11} uc/ml.

10.5.3.2.1 Continuously Monitored Filter Paper Samplers

Filter paper samplers with gas flow proportional detectors and count rate displays are used to continously monitor air exhausted from the processing areas, work areas and the facility exhaust system. Four of these units monitor both alpha and beta-gamma activity in the air and alarm upon a change in ratio between the alpha and the alpha-plus-beta-gamma count rate.

10.5.3.2.1.1 Continuous Air Monitor Sample Locations, Controls and Interlocks

Four continuous air monitors sample and control the air handling systems to minimize dispersal of

radioactive contamination from the cell areas to other parts of the facility. Reference Figure 6.2 Air Handling System.

10.5.3.2.1.1.1 Monitor No. 1. (M-1)

This unit monitors the air in the combined discharge duct from the process box exhaust fan and on indication starts Fan E-14 and stops the normal Fan E-13, at the same time the individual dampers are activated and an alarm is sounded on the alarm panelboard in the operating area.

10.5.3.2.1.1.2 Monitor No. 2 (M-2)

This unit monitors the air in the combined cell exhaust duct and on indication starts auxiliary Fan E-4, opens auxiliary motorized exhaust dampers, stops all normal cell exhaust Fans E-5 through E-10 and closes all normal exhaust dampers. At the same time, air supply Fans SH-2, UC-2 and exhaust Fan E-11 are shut down.

10.5.3.2.1.1.3 Monitor No. 3 (M-3)

This unit monitors the air in the service area and on indication stops air supply Fans SH-2, UC-2 and exhaust Fan E-11.

10.5.3.2.1.1.4 Monitor No. 4 (M-4)

This unit monitors the air entering the recirculating duct in the operating area, and on indication stops air supply Fans SH-2, UC-2 and exhaust Fan E-11.

10.5.3.2.1.1.5 Monitor No. 5 (M-5)

This unit is used to monitor for sudden changes in airborne contamination during various operations in the service area, isolation rooms, radiochemical laboratory or decontamination area. Since the unit is transportable, it is not interlocked to any particular system and is moved to the best sampling locations to monitor individual operations in progress.

10.5.3.2.2 Fixed Filter Paper Samplers

A central vacuum system adjusted to sample at a rate of 1 cfm per sampling point, is used to collect samples from various locations in the air handling system to evaluate the performance of the ventilation system filters. (Reference Figure 6.2 Air Handling System). These filter paper air samples are normally changed and radioassayed daily from approximately thirty different locations making it possible to detect ventilation system filter deterioration so that corrective action can be taken before a serious problem develops. Small low volume air pumps are used to collect fixed filter paper air samples from each stack discharging to atmosphere. In addition, another unit is used to sample outside air.

10.5.3.2.2.1 High Volume Air Samples

Grab samples of air are collected prior to, during, and after various operations which may produce airborne contamination. A small high rpm motor is used to draw a high volume (up to 20 cfm) of air through a four inch diameter filter

paper. These samples are evaluated in order to determine the airborne contamination levels. Sample times for the collection of high volume air samples vary from 5 to 20 minutes.

10.5.3.2.3 Counting Air Samples

Filter papers used to collect samples of particulate airborne radioactivity are counted utilizing gas flow proportional detector/scaler assemblies. High volume air samples are counted in a large area gas flow proportional detector which is capable of accepting the entire filter paper.

10.5.3.3 Monitoring for Liquid Contamination.

Water samples are collected and analyzed for gross beta-gamma activity from the potable water supply, the source storage pool, nearby streams and liquid waste holdup tanks.

10.5.3.3.1 Description of Water Sample Preparation and Counting

A 500 to 1,000 ml water sample is evaporated to approximately 10 ml; transferred to a planchet and evaporated to dryness. The planchet is counted for gross beta-gamma activity in a gas flow proportional detector/scaler assembly. Results of sample analysis are recorded in μc/ml. The procedures utilized allow detection of less than 1×10^{-8} μc/ml.

10.5.4 Records

Radiation and contamination survey results are recorded on sketches of the areas where the survey was performed and are filed in the Health Physics Office.

Air samples results are recorded on air sampling record forms and also filed in the Health Physics Office.

Liquid sample results are also maintained in the Health Physics Office with the exception that Pennsylvania State University maintains the original copy of the results of liquid radioactive waste discharged to the environs.

10.6 Personnel Monitoring

Individuals entering the facility are provided with a personnel monitoring device(s) for determinating radiation exposure. Knowledge of general dose rate and exposure time gives an estimate of personnel exposure, but a more accurate determination is made utilizing personnel monitoring equipment.

10.6.1 Analysis of Exposures

Correlation of job assignments with doses received by individuals sometimes indicates a need for revision of certain job procedures or further training of personnel in the interest of minimizing radiation exposures.

10.6.2 Types of Personnel Monitoring Devices

Two types of personnel monitoring devices, namely film badges and pocket dosimeters, are currently used to provide information regarding personnel exposure.

10.6.3 Description of Film Badge and Film

The film badge currently used at the facility can accommodate two film packets, but is used to hold one Dupont Type 558 film packet for X, beta and gamma radiation detection. The front portion of the badge contains a metallic filter and clear plastic windows used for photon energy determination and distinguishing between beta and gamma radiation. The film is dated adjacent to the clear plastic window to indicate the wearing period. The wearer's name, and identification number are conspicuously displayed on the front of the badge.

10.6.3.1 X, Beta and Gamma Film

Dupont Type 558, or equivalent personnel monitoring film, is used to measure exposures at this facility. This packet contains the sensitive type 508 and the insensitive type 1290 giving a useful dose range up to 600 rem.

10.6.4 Wearing Film Badges

All personnel requiring access to or working in posted radiation areas, or handling radioactive or contaminated materials in or adjacent to the facility are required to wear film badges. These badges are normally worn clipped to outer clothing. During operations where contamination is likely to be present, film badges are worn on innermost clothing to avoid contamination of the badge.

10.6.5 Loss of Film Badge

Any person who loses his badge has been instructed to immediately notify Health Physics to obtain a replacement. Any lost or damaged film badges would be investigated by Health Physics to determine the exposure for the unmonitored period and a report would be written for the personnel monitoring records.

10.6.6 Issuance and Frequency of Film Badge Exchange

The loaded film badges, along with control badges, are placed on racks at a convenient point for their distribution. Operating personnel have been cautioned to occasionally check to see that they are wearing their assigned badge.

At the termination of the work period, all personnel are responsible for returning their badges to the distribution rack. Personnel have been instructed not to take their badge with them when leaving the site.

The frequency of film badge exchange is established by Health Physics and is based upon type of the work being done and anticipated exposures. The normal exchange period is one week, however it is not anticipated to extend it beyond two weeks. At the end of the prescribed wearing period, the used badges are replaced and are submitted for evaluation.

10.6.7 Film Processing

All film badges are checked for contamination prior to submitting the film for processing. Any evidence of contamination is noted and an attempt is made to decontaminate the badge and determine the true exposure. Film badges may be submitted at any time for evaluation. The film processor currently retained under contract is Health Physics Services, Baltimore, Md.

10.6.8 Reports and Records

When film has been processed and the exposure evaluated, the completed radiation report form is sent to the resident Health Physicist; a duplicate copy is sent to the Baltimore Health Physics Office. The current exposure information is transposed to the individual's own exposure report form where a cumulative exposure record is brought up to date. A record of all personnel exposures is kept on file for a period in accordance with 10CFR20.

A comprehensive report of all statutory overexposure incidents will be submitted to management by Health Physics. This report will include an analysis of the cause, and when possible recommendations to prevent recurrence of the incident. Copies of this report will be submitted to the Commission in accordance with the requirements as set forth in 10CRF20.

10.6.9 Other Uses for Film Badges

Film badges are used for area monitoring, monitoring of personnel extremities, and checking film badge service evaluation.

10.6.10 Use of Pocket Dosimeters

Pocket dosimeters are available in the ranges of 0-200 mr, 0-1r and 0-5r, and are worn in accordance with instructions from the Health Physics representative on duty. Usually one low range and one high range dosimeter are worn when conducting work in radiation areas.

10.6.10.1 Issuance and Handling of Pocket Dosimeters

Pocket dosimeters are charged and issued by Health Physics personnel. Each person receiving a dosimeter is instructed to read it periodically and to report the reading to his supervisor or the Health Physics representative on duty. At the end of the work period, the dosimeters are returned to Health Physics and the readings are recorded in the Health Physics log book.

10.6.11 Medical Examination

All employees are required to submit to a medical examination prior to work in areas where ionizing radiation exposure may be involved and routine examinations are conducted periodically thereafter. Special medical examinations are required in the event of unusual or suspect exposures. Arrangements have been made for a nuclear medical

consultant to perform these special examinations. Copies of records of all medical exams are retained by the medical department in Baltimore.

10.6.12 Bioassays

Bioassay samples are submitted for analysis by all personnel working with radioactivity. During the early months of hot operations bioassay samples were collected and analyzed on a frequent schedule, and the results were used to establish the present sampling schedule. The exact sampling schedule is governed by the type of work performed and the potential for internal contamination based upon surveys. In any event, all persons working with or exposed to radioactive material are sampled at least quarterly. If an individual is known or suspected to have been exposed to radioactive contamination in such a manner that internal deposition is likely, an estimate is made of the internal dose for inclusion in the individual's radiation exposure record. If in a more accurate determination of the body burden is required, arrangements shall be made to utilize a total body counter.

10.6.13 Records

Records of all bicassay results are maintained at Quehanna and Baltimore and are posted in each individual's file.

10.7 Personnel Protective Clothing and Equipment

Any equipment which aids in preventing the deposition of radioactive contaminants onto or within the body may be considered anti-contamination protection. Protective clothing provided by the company is worn when access to a contaminated area is required, or there is a possibility of the release of contamination as the result of some operation. The Health Physics representative on duty shall specify the minimum type and items of protective clothing to be worn and shall inspect their use. This equipment is stored in the change room and is donned prior to entry into contaminated areas.

10.7.1 Protective Clothing

10.7.1.1 Plastic and/or rubber shoe coverings are worn whenever contamination is expected. Coveralls are tucked into the shoe covers and taped prior to entering highly contaminated areas.

10.7.1.2 Gloves are normally worn in areas where contamination may be present. The gloves are taped to the sleeves prior to entering highly contaminated areas. Rubber gloves are always worn when dealing with contaminated liquid.

10.7.1.3 Hoods or caps are used to prevent contamination of the head. Plastic hoods are used in cases where liquid contaminants may be present.

10.7.1.4 Cotton coveralls are issued for protection of the whole body against dry contamination. Coveralls are rarely worn over personal clothing except undergarments.

10.7.1.5 Plastic suits are worn over the coveralls whenever liquid contamination is anticipated or suspected and also worn as outer garments over coveralls when entering highly contaminated areas.

10.7.2 Breathing Equipment

The following types of respiratory protective equipment are available:

(a) Full Face Respirator - Mechanical Filter Type

(b) Scott Pressure Damand Hose Line Equipment

(c) Supplied Air Plastic Hood - Continuous Flow Type

(d) Scott Air Paks - Positive Pressure Facepiece

(e) MSA - Chemox

} Maintained as part of the emergency equipment.

All personnel receive instructions on the proper use of respiratory protective equipment. Such aspects as the proper fitting of filter elements, damage to filter elements, proper fit of the mask to the face, etc. are emphasized. Personnel are instructed to wear mechanical filter type full face respiratory equipment whenever a potential exists for

airborne contamination. The efficiency of the respirator filter units are checked by the manufacturer before shipment. All respiratory equipment is inspected by Health Physics before use for mechanical integrity. It is felt that careful inspection and use is adequate to guarantee the effectiveness of the mechanical filter type respirators since they are not used where air concentrations could result in serious overexposure to the wearer.

Scott pressure demand hose line equipment or supplied air-plastic hoods are used when the preoperational survey indicates air contamination in excess of MPC or the concentration is expected to be highly variable. Scott pressure demand hose line equipment consists of a full facepiece, short length of flexible tubing, an air flow control device designed to maintain a slight positive pressure in the facepiece, an air supply hose equipped with quick disconnect fittings, pressure reducing regulator and compressed air supply.

Supplied air plastic hoods consist of either a plastic hood fastened at the chest and back and worn beneath the upper portion of a two piece plastic suit with the hood taped at the collar of the plastic jacket, or a hooded plastic blouse. The hood being an integral part of the upper portion of the plastic suit. The plastic air supply hose is introduced through the back at the waist and extends upwards through the hose retaining channel in the hood and terminates above the forehead.

The hose is fastened at the top of the hood and at the waist to prevent accidental removal. The plastic air supply hose used is a continuous piece equipped with a quick disconnect fitting connected to an air flow regulator and subsequent air supply. During use, the air supply is adjusted to maintain a minimum flow rate of 6 cfm through the hood. Currently the compressed air supply, used exclusively for breathing air, consists of a bank of cylinders interconnected to allow exchange of cylinders during use without interuption of air supply. This air supply is located outside the work area and is continuously attended when in use.

10.7.3 Classification of Protective Clothing and Equipment

Table 10.2 presents the protective equipment classifications currently utilized at the facility. The Health Physics representative on duty specifies the class of protective clothing to be worn by individuals entering contaminated areas. The protective equipment prescribed is determined on the basis of the preoperational survey or prior operational experience.

10.7.4 Description of Entry Into Radiation - Contamination Areas

10.7.4.1 The protective equipment specified by the RWP is obtained in the change room area. Certain items of equipment are donned in the change room.

TABLE 10.2

CLASSES OF PROTECTIVE CLOTHING

Class	Cover-Alls	Head Cover	Shoe Cover	Gloves	Plastic Jacket and Trousers	Full-Face Respirator	Plastic Hood Supplied Air or Airline Respirator	Surface Contamination Level	Potential for Airborne Contamination Due to Nature of Work
1	Coveralls or Lab Coats		X	Depends upon work				< 500 dpm	None
2	X	Cap	2 pr	X				> 500 dpm < 5000 dpm	Measured <MPC not expected to exceed MPC
3	X	Plastic Hood	2 pr	2 pr	X	X		> 5000 dpm	Measured <MPC may exceed MPC but <50X
4	2 pr	Plastic Hood	2 pr	2 pr	X		X	> 5000 dpm	Measured >MPC variable and could be >50X

10.7.4.2 Personnel monitoring equipment, including any supplementary film badges, wrist badges and dosimeters as specified, is attached in the change room.

10.7.4.3 Personnel proceed to the general work area and assemble all necessary equipment such as tools, meters, decontamination supplies, etc. required to perform the job.

10.7.4.4 Additional protective equipment is donned prior to entering the specific work area.

10.7.4.5 Personnel proceed to the job site and perform the task in accordance with specific operating procedures.

10.7.4.6 When applicable, the Health Physics representative notifies the personnel when their time limit has expired and the personnel leave the job site.

10.7.5 Description of Egress from Radiation - Contaminated Areas

10.7.5.1 Upon completion of the work task or expiration of time limit, personnel leave the specific job site.

10.7.5.2 Monitor and remove outer protective equipment as required to minimize the spread of contamination. Place contaminated equipment in containers provided near the job site.

10.7.5.3 At the completion of the job, all tools and equipment are placed in clean plastic bags at the job site and stored or placed in the decontamination room for survey and/or decontamination.

10.7.5.4 Personnel proceed to the change room to remove their remaining protective equipment, place it in designed containers, and perform personal monitoring utilizing the G.M. count ratemeter.

10.8 Decontamination

Decontamination is the process of removing contaminants by physical or chemical means. Survey techniques for contamination measurements were previously described in 10.5.3.

10.8.1 Decontamination of Areas

Decontamination of areas is carried out as soon as possible after detection. This not only reduces the possibility of airborne contamination hazards, but the contamination is more easily removed before it has a chance to become fixed. The protective clothing requirements for personnel performing decontamination are established by Health Physics based upon the results of surveys. Many areas where contamination is expected to result from a job are covered prior to performing any work. Coverings include paper, polyethylene, metal foil, and strippable paints.

10.8.1.1 Removal of Contaminated Coverings

Contaminated coverings are normally taken up by rolling the contaminated side in on itself. Care is exercised when handling contaminated materials to prevent the contamination from becoming airborne. Strippable painted coverings are recovred

with additional paint prior to removal. This step tends to fix the contamination and reduces the airborne hazard.

10.8.1.2 Wiping Contaminated Surfaces with Dust Absorbing Cloths

"Masslin" or other treated dust-retaining cloths may be used to wipe smooth surface areas which require decontamination. For large areas, such as floors, the cloths are mounted on long handled fixtures and gently pushed across the floor. For smaller areas and equipment, the cloths are held in the gloved hand. The cloth is frequently turned to present a clean surface to the area being decontaminated. The cloth is also frequently surveyed to detect the degree of contamination being removed. Contaminated cloths are discarded in the radioactive waste containers.

10.8.2 Decontamination of Equipment

Decontamination of equipment is accomplished in the decontamination room, isolation rooms, or other areas suitably prepared to handle potential contamination arising from decontamination operations.

10.8.2.1 Washing and Scrubbing

Washing and scrubbing with detergents and other chemical agents such as acids, alkalis, and chelating agents are generally effective for removing dirt and grease along with contamination from surfaces. This method is employed where small

pieces of equipment are to be decontaminated. Manipulator wrists and similar equipment are immersed in buckets of detergent solution and scrubbed under water to loosen small particles of contamination. They are withdrawn from the detergent solution, dried with rags and reoiled immediately to prevent corrosive galling. Waste rags and liquid are discarded as radioactive waste.

10.8.2.2 Steam Cleaning

Where possible, large pieces of contaminated equipment are steam cleaned. Precautions are taken to avoid plugging and subsequent damage of the ventilation system filters and to collect the steam condensate in containers for treatment as liquid radioactive waste. This method of decontamination is quite effective, especially when detergents are mixed with the steam, however, since facilities for handling large quantities of liquid waste are limited, it is rarely used.

10.8.2.3 Ultrasonic Decontamination

This specialized method of decontamination is normally used to decontaminate small parts. Ultrasonic decontamination tanks are installed in the process box for decontaminating fuel capsules.

10.8.3 Decontamination of Protective Clothing

All protective clothing is monitored and segregated into two groups according to the quantity of contamination

present. Group A consists of items indicating less than 6 mrad/hr and Group B more than 6 mrad/hr, but less than 12 mrad/hr average contamination over the entire garment when read at one inch from the surface of the item with a G.M. survey meter. These items are placed in plastic bags, tagged according to radiation level, placed in a shipping container and shipped in compliance with I.C.C. regulations to an approved off site laundry decontamination service. This service is currently being provided by Nuclear Laundry Service, Jeannette, Pa. Items of protective clothing, contaminated above 50 mrad/hr are discarded as radioactive waste.

10.8.4 Decontamination of Breathing Equipment

Breathing equipment is surveyed by Health Physics after completion of jobs where this equipment was used. Noncontaminated equipment is either returned to individuals to which it was assigned, or is stored in the equipment issue area after cleaning. Contaminated equipment is handled as follows:

10.8.4.1 Contaminated face pieces are washed with a detergent in warm water, thoroughly rinsed in warm water, dried surveyed and packaged in a plastic bag.

10.8.4.2 Used respirator filters are discarded.

10.8.4.3 Metal parts of supplied air breathing equipment are washed with warm soapy water and/or wiped with "Masslin" or other suitable contamination removing cloths. Persistent

contamination is removed by scrubbing in mild chemical solutions. The items are dried and surveyed prior to storage.

10.8.4.4 Strap webbing is washed in warm soapy water, dried and surveyed.

10.8.4.5 Airlines are discarded after use.

10.8.4.6 Plastic hoods worn in conjunction with supplied air are discarded after use.

10.8.5 Decontamination of Personnel

10.8.5.1 General Washing Procedure

Thorough washing with mild soap and tepid water is the best general method for removing contaminants from the hands or body. If the contamination is localized, it is often more practical to mask off the affected area and cleanse with swabs, before risking the danger of spreading the contaminants. Repeated washings and rinsings may be necessary, however, care should be exercised not to abrade the skin. Applications of lanolin or hand cream may be desirable to prevent chapping after repeating washings. If contamination persists, the following method may be used under Health Physics supervision: Apply a 10% solution of potassium permanganate, rinse in warm water and apply a freshly prepared solution of sodium bisulfite. Rinse thoroughly and wash with a mild soap.

CAUTION: These solutions should not be allowed to remain in contact with the skin for more than 2 minutes per washing.

In the event that contamination cannot be removed by employing these methods, additional decontamination shall be attempted under the direction of the resident Health Physicist with the advice of a consulting physician.

10.8.5.2 Decontamination of Injured Personnel

Decontamination of superficial wounds shall be performed under the supervision of the resident Health Physicist. Services of a consulting physician will be utilized based upon the degree of injury. Arrangements have been made with local physicians and the Clearfield Hospital to provide any necessary medical assistance. In addition, a Nuclear Medical Consultant from the University of Pittsburgh Graduate School of Public Health has been contacted to provide professional services when required.

10.8.6 Decontamination of Liquids

Information regarding liquid waste handling methods is described in Chapter 7.

10.8.7 Decontamination of Air (Air Handling System)

Filters are installed in the air handling system to remove particulate radioactivity resulting from process operations prior to discharge to the environs. A description of the air handling system is presented in Chapter 6.

10.8.8 Storage and Control of Contaminated Material and Equipment

Equipment that cannot be decontaminated immediately is sealed in plastic and stored in the decontamination room. Items of equipment which are used only in contaminated areas on a periodic basis are also sealed in plastic and stored in the decontamination room when not in use.

Pieces of equipment presenting a serious radiation hazard due to the amount of contamination present are decontaminated or discarded as radioactive waste.

10.9 Waste Disposal Monitoring

A description of the methods employed for the disposal of radioactive wastes is presented in Chapter 7.

10.9.1 Monitoring Solid Waste Disposal Containers during Filling and Removal from the Facility

During the removal of solid radioactive waste from the cells and process box, a Health Physics representative monitors for external radiation, surface and airborne contamination. The waste containers are surveyed for surface contamination prior to removal from the cell isolation room after sealing the disposal container. Contaminated containers are decontaminated prior to removal to the waste storage area. All containers of radioactive waste are labeled and tagged in accordance with the applicable regulations.

10.9.2 Monitoring the Solid Waste Disposal Container Storage Area

Sealed radioactive waste disposal containers are moved from the facility to the waste storage building where they are stored until shipped to an approved disposal site. The radioactive waste storage area is monitored at least weekly for external radiation. The general radiation level is posted at a location where it can be observed by personnel entering the area. The storage area is posted with radiation signs in accordance with applicable regulations.

10.9.3 Monitoring Shipping Vehicles

Vehicles used to ship radioactive waste containers to the disposal site are monitored during loading operations. Containers are arranged so that those emitting the maximum radiation levels are shielded by those of lower radiation levels. The exterior of the shipping vehicle is monitored and posted to assure compliance with shipping regulations prior to leaving the site.

10.9.4 Records

Any entry is made in a Solid Radioactive Waste Disposal Log Book after waste containers have been transferred to the waste storage area. This entry includes the radiation level at the surface of the container, the level at one meter from the container surface, an indication of the curie content

of the container, results of surface contamination surveys and container weight. These records are maintained by both Health Physics and the administration and are used when loading trucks for waste shipments.

10.9.5 Monitoring Liquid Radioactive Waste

Process liquids are absorbed and treated as solid radioactive waste as described in Chapter 7. Low level liquid waste is monitored by Pennsylvania State University personnel who are responsible for the discharge of liquid waste to the facility environs. Liquid waste samples are collected and analyzed by Penn State personnel under the supervision of the University Health Physics officer. Dilution factors, as required, are supplied by Pennsylvania State University to facility operations personnel, who adjust the flow of dilution liquid so the waste discharge is conducted in compliance with applicable regulations.

10.9.6 Monitoring Liquid Waste Treatment Facilities

Health Physics conducts periodic radiation and contamination surveys in the liquid waste treatment facility. The frequency of surveys is governed by facility utilization. Results of these surveys are recorded and reported to the Plant Manager.

10.9.7 Liquid Waste Discharge Records

Records of the activity of liquid waste discharged to the environs are maintained by the Pennsylvania State University Health Physics Office. Duplicates of these records are also retained in the Health Physics files at the facility.

10.10 Health Physics Instrumentation

An adequate supply of instruments, capable of detecting and measuring ionizing radiation throughout the facility, are maintained as Health Physics equipment. Table 10.1 presents a list of the typical instruments.

10.10.1 Description of Instrumentation Check and/or Calibration Method and Frequency

10.10.1.1 Air Particulate Monitors

The continuous air monitors are functionally checked at least once every 3 months or after each servicing. This check includes utilization of a calibrated strontium-90 reference source placed in view of the detector. If the instrument reading varies beyond ± 20% from the known value of the source, the instrument is adjusted and/or repaired. In addition, the air flow is measured using a calibrated rotameter and adjusted to 4 cfm.

10.10.1.2 Area Radiation Monitoring System

The area radiation monitoring detectors are functionally checked at least once every 3 months or after each

servicing. This check includes utilization of a 25 mg radium source placed at varying distances from the detector in order to check the reponse of the detector. If the meter reading varies beyond 20% from the true reading, the equipment is adjusted and/or repaired.

10.10.1.3 Detector/Scaler Counting Assemblies

All counting room instrumentation is checked daily for background and statistical accuracy. A calibrated strontium-90 source is placed in each detector and counted for a preset time. The background and total count is recorded in a log. If the instrument readings vary greater than the calculated statical error, it is recalibrated and/or repaired.

10.10.1.4 Count ratemeters - Hand and Foot Counter

The count ratemeters are functionally checked at least once every three months or after each servicing. This check includes utilization of a calibrated strontium-90 source placed in view of the detector. If the instrument readings vary beyond ± 20% from the known value of the source, the instrument is adjusted and/or repaired.

10.10.1.5 Portable Radiation Detection Instruments

The portable survey meters are calibrated at least once every three months or after each servicing. This calibration includes utilization of a 25 mg radium source and a Martin custom encapsulated 7-curie strontium-90 titanate pellet.

If the instrument readings vary beyond ± 20 from the known dose rate established with a R-meter, the instrument is adjusted and/or repaired.

10.10.2 Instrument Maintenance and Records

Minor instrument repairs and calibrations are performed by Health Physics personnel. Major repairs are performed by the facility instrument technician.

Health Physics maintains permanent records of all instrument calibrations and repair records are maintained by the instrument technician. Each instrument is tagged indicating the calibration date.

10.11 Environmental Monitoring Program

Effluent monitoring data collected since plant startup indicates that during normal operation, no radioactivity in excess of the limits set forth in 10CFR20 is released to the environs.

A practical environmental monitoring program has been developed for the Quehanna site. Consideration has been given to the geographic, geological, hydrological and meterological aspects of the site, as well as to the influence of low population density and the operational activities conducted at the Martin Radioisotope Pilot Plant. The purpose of this program is to obtain data on the normal variations in background radiation which can be used to assess the effect of an accidental release of radioactive material to the environs.

This program includes collection and analysis of: stream water, silt, soil and vegetation, and environmental air.

10.11.1 Samples Location and Frequency

Samples of the environs (refer to Figure 10.1) are collected as accessibility to the sample locations permit on the following schedule:

LOCATION	SAMPLE	FREQUENCY
#1	Water	Monthly
	Soil and Vegetation	Twice per Year
#2	Water	Monthly
	Silt	Twice per Year
#3	Water	Monthly
#4 & 5	Water	Monthly
	Silt	Twice per Year
#6 & 7	Soil and Vegetation	Twice per Year
#8	Environmental Air	Daily
#9	Water (Facility Potable Water)	Daily
#10, 11, 12	Soil and Vegetation	Twice per Year
#13, 14	Water	Monthly
	Silt	Twice per Year

10.11.2 Sample Size and Analysis

One liter of water, approximately 10 gms of vegetation and one pound of soil are collected and analyzed for gross beta-gamma activity. Selected proportions of the samples collected are analyzed for strontium. Records of analysis are maintained by Health Physics.

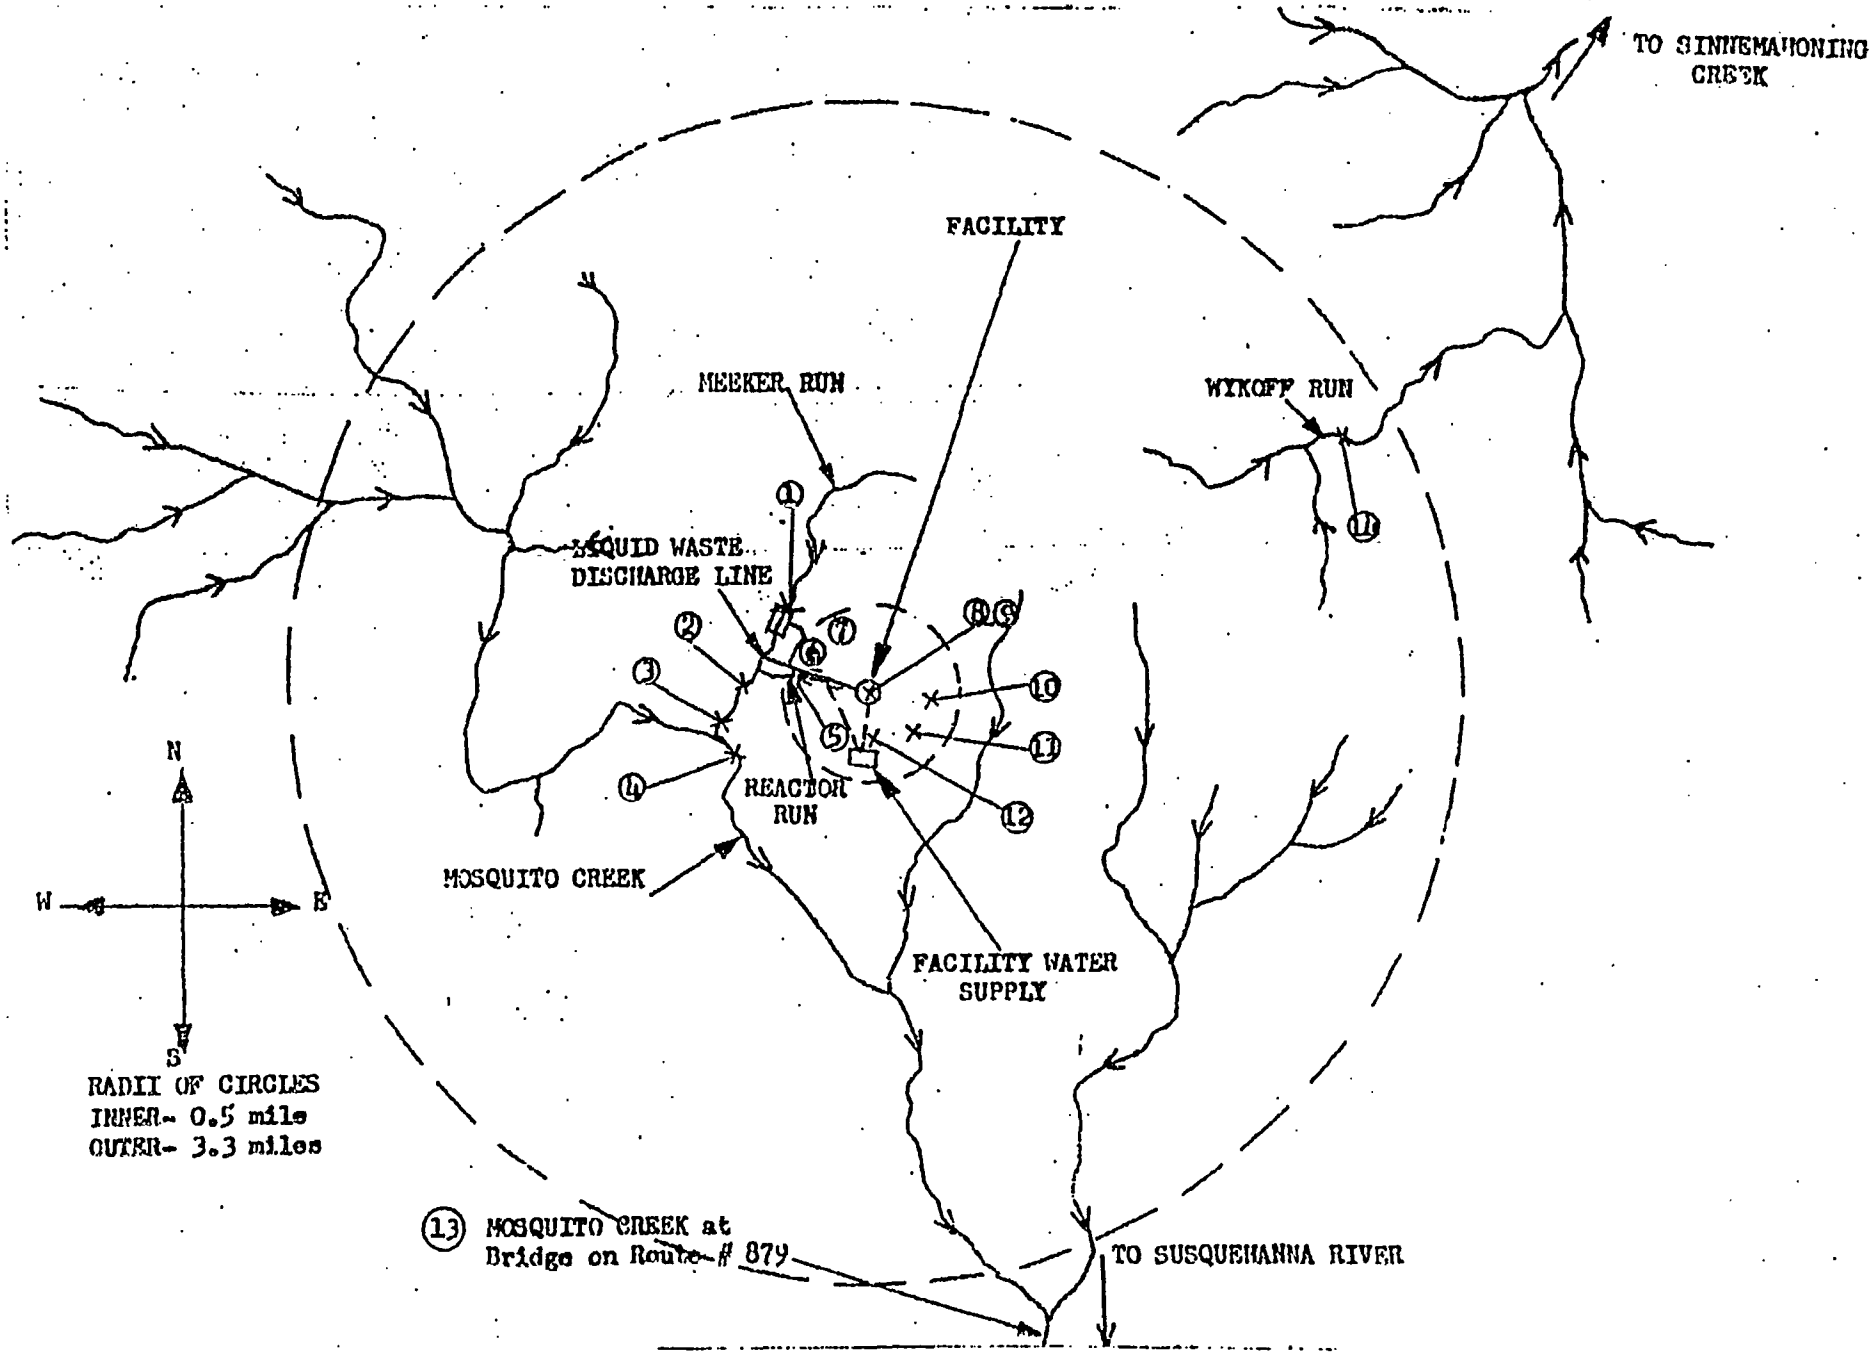

FIGURE 10.1 ENVIRONMENTAL SAMPLING POINTS

CHAPTER 11

SUMMARY OF EMERGENCY CONTROL MEASURES

11.1 Introduction

The Quehanna Radioisotope Production Facility has processed kilocurie quantities of $SrTiO_2$ since July 1962 and much valuable operating experience has been gained. This valuable information has influenced the design of new equipment and the planning of a safe operation. This section presents a summary of the available means for dealing with emergencies. While it is not possible to predict all the accidents that may occur, it is felt that the equipment provided, combined with intelligent understanding of the facility and careful preplanning, make it possible to deal with any emergency that may arise. Detailed emergency that may arise. Detailed emergency procedures are outlined in the Standard Operating Procedures.

11.2 Local Assistance

Pennsylvania state and local police, Pennsylvania State Health Department, hospital and civil defense authorities have been contacted and arrangements completed for mutual assistance in the event of an emergency. These officials are aware of the facility operations and an efficient system for emergency assistance has been agreed upon. Local volunteer fire departments have visited the facility and are familiar with the plant fire fighting equipment.

11.3 Organization

The Plant Manager supervises the emergency control procedures. He issues any alternative procedures which he may feel necessary to cope with a particular situation. It is also his responsibility to report an emergency incident to responsible authorities of Martin, the facility owner (Pennsylvania State University), and the AEC in accordance with the requirements as set forth in 10CFR20. In the absence of the Plant Manager, the shift foreman will assume the responsibility of evacuation coordinator until the Plant Manager arrives on the site.

11.4 Health Physics

The resident Health Physicist acts as consultant on radiation and contamination problems and reports the hazards to the evacuation coordinator. Detailed duties are covered in the Standard Operating Procedures.

11.5 Off-Hour Coverage

During processing of radioactive material, at least two persons will be in attendance at all times. In case of any emergency, the Plant Manager and the resident Health Physicist will be notified.

11.6 Equipment

In addition to the support equipment, ventilation air monitoring systems and controls, the facility maintains and operates an emergency vehicle and trailer outfitted with equipment

for detecting and measuring air contamination and radiation levels in the site environs. The unit also contains protective clothing and equipment, decontamination supplies, an emergency generator and other items necessary for handling emergency situations.

11.7 Emergency Drills

Drills are held periodically in order to train the personnel in the proper procedures to follow in case of a radiation or particulate release alarm. All personnel evacuate the facility at the sound of the alarm and congregate in the parking lot. In the event of a real alarm, they will remain in the lot until the Plant Manager and the Health Physicist can determine the cause of the alarm and plan immediate action.

Dosimetry and follow-up procedures are conducted on all personnel who may have become contaminated or exposed. (Reference Chapter 10 - Health Physics).

11.8 Internal Emergencies

11.8.1 Liquid and Dry Spills

In case of major contamination due to a spill or other accident within the building, the contaminated area is marked by Health Physics and decontamination procedures are initiated. Appropriate protective clothing is worn during this time (see Paragraph 10.7.3).

11.8.2 High Air Contamination

The room constant air monitors have a set and an alarm point. In case of an air monitor alarm, all personnel immediately don protective respiratory gear and Health Physics evaluates conditions and advises regarding the course of action. In the event of an evacuation the emergency coordinator and the senior health physicist don respiratory protective and evaluate building conditions. Ventilation is adjusted to minimize the spread of contamination and decontamination procedures are initiated utilizing appropriate protective equipment.

11.8.3 High Radiation Levels

The ventilation system sample filters are changed daily and in case a filter becomes unduly contaminated. While the contaminated filter is being changed, an emergency fan is started and the flow by-passes the contaminated filter.

11.8.4 Leaking Capsule in Pool

If a leak should occur in one of the fuel capsules in the storage pool, it will be detected by either Health Physics analyses of the water or the continuous water monitor. The process by which the leaking capsule is isolated entails the use of a hollow, siphon-fitted can which, when placed around the suspect capsule, draws water to be sampled for excess activity. In addition to water samples, the deionizers which service the storage pool through a continuous recirculating system are monitored on

a regular basis. When a capsule is removed from the pool, smears are taken at the earliest convenient time.

11.8.5 Pool Leakage

The following action is taken if the storage pool should leak: the pool water supply is increased to maintain shielding over the fuel capsules; environmental monitoring is initiated to measure the radiation in the area. The cause of the leak is determined by the Plant Manager and Health Physics, and repairs and preventive remedies are initiated.

11.9 External Release

11.9.1 Airborne

If contaminated air should be released to the environment, a survey will be conducted to determine the extent. A high volume air sample mounted on the facility emergency trailer will be used for sample collection and radiation levels will be recorded.

11.9.2 Water Contamination

Contamination of the environmental water system could result from accidental release of high level liquid waste from the waste treatment plant. In this event Health Physics is made aware of the situation via the alarm systems. Water samples of local streams will be collected. After a period of time following an incident, silt samples from the streams will be collected. The proper agencies throughout the area will be notified.

11.10 Fire Fighting

11.10.1 Fire Fighting Plan

In addition to the general problems involved in in fighting fires, the Quehanna Pilot Plant is faced with two special problem areas. These problems are:

(1) Fighting laboratory fires involving acids, gases, chemical processing apparatus, electrical equipment and other hazardous materials normally found in a laboratory.

(2) All of the above, plus the added hazard that radioactive materials may be present in the area or disseminated in the atmosphere.

A training program is designed to provide a general background and experience (through field demonstrations) in fighting fires, with emphasis on the special precautions required by virtue of the special conditions.

The design of the facility lends itself readily to the establishment of a three-area control system. The areas in which a fire would produce the most serious consequences are the hot cells. In the event of such a fire all efforts will be made to confine the radioactivity to the area while putting out the fire. The second area is the isolation room. If necessary to put out the fire, and if it cannot be confined to the hot cell, radioactivity may be allowed to spread, under control, to the isolation room. The service area provides a third region, the

cold area, from which the fire may be approached. If at all possible, radioactive contamination will be kept from this area.

The facility has highly trained personnel, competent in matters pertaining to radiation and radioactive materials control. Most of the training is therefore directed to those problems associated with the proper use of equipment, techniques, philosophy of the three area control and location of emergency supplies. The Pennsylvania State University Fire Marshal and a representative of the NEPIA Agency are available as consultants. Both individuals make periodic inspections and inform the Plant Manager of any deficiencies in the equipment, or new techniques that may be incorporated in the protection plan.

11.10.2 Fire Alarms and Equipment

Fire fighting equipment is installed in and about the building in accordance with the requirements of the National Board of Fire Underwriters. Most sections of the building in which radioactive work is not carried on are protected by an automatic sprinkler system. When any part of this sprinkler system is actuated, an alarm will sound throughout the building. It is also arranged that an alarm will sound if the water pressure in the sprinkler system drops below a preset level.

It is not practical to use sprinkler systems in most areas where chemical and radioactive work take place because the reagent which should be used to put out the fire depends

largely on the burning material and other materials in the laboratory. Sprinkler systems also tend to spread radioactive contamination. In such areas, therefore, automatic fire detectors have been installed. If the temperature in one of these areas rises above a preset limit, it will result in the continuous ringing of all fire alarm bells throughout the building. Automatic detectors are located in the reactor bay, remote control room, reactor pump room, mezzanine fan rooms, operating area, above the isolation rooms, the service area, decontamination room, and the analytical radiochemistry lavoratory.

The entire fire alarm system will operate from the normal power bus. In case of power failure, the system will automatically switch over to storage batteries. Provisions are made for the system to be connected to a future central fire station.

In the areas in which only fire detectors are installed, it will be necessary to combat fires with locally available fire extinguishing apparatus. The extinguishing reagents include water, foam, carbon dioxide, and powdered sodium carbonate. The reagent to be used depends upon the type of fire.

There is no provision for fixed sprinkler or automatic fire detector equipment in the hot cells. Each experimental installation is evaluated individually for an associated fire hazard, and appropriate alarm and/or fire extinguishing apparatus is installed with the experimental equipment as required.

11.10.3 The Training Program

Because of the relatively small staff at the Quehanna Radioisotope Pilot Plant, all men are members of the Fire Brigade and will receive fire fighting training. Three hours of preliminary training will be provided in the course of training programs related to Health Physics and the strontium-90 titanate process. The special hazards caused by the particular systems at the facility and the chemical systems to be operated will be reviewed, and techniques for emergency action presented and practiced. Additional classroom training of one hour per quarter will cover such items as alarm code instruction, evacuation procedures, emergency treatment, familiarization with equipment and other related topics. During favorable weather, the fire fighting equipment will be tested in these classes. Field exercises will include techniques of handling high pressure hose and various types of extinguishers. Proper maintenance of hose and equipment after use will be learned. Classes will be conducted by the plant Fire Marshal although any member of the staff or the aforementioned consultants may provide the actual instruction. The following reports will be required reading and will serve as texts for the instruction:

1. Living with Radiation - Volume II
   Fire Service Problems
   U. S. Atomic Energy Commission

2. The Hazard of Radioisotopes under Fire Conditions

Factory Insurance Association

3. Recommended Fire Protection Practices for Nuclear Reactors,

NFPA 802

As part of the training already given, fire hoses are checked periodically.

11.10.4 Specific Emergency Procedures

11.10.4.1 Fires or Explosions in Process Box—

11.10.4.1.1 Detection

Flammable materials are rarely used in the processing box and the only other possibility is an electric motor becoming overheated. Since the facility is never left unattended visual detection of fires and subsequent remedial action is possible.

11.10.4.1.2 Standard Procedure

The cell operator must do the following things in the event of a fire or explosions:

a. Sound fire alarm if not already done.

b. Don respiratory protection device.

c. Use extinguishing chemicals and reduce air flow via manual damper control.

d. Leave the area if radiation or evacuation alarm sounds.

The emergency coordinator is required to:

a. Check performance of cell operator and assist if necessary.

b. Assure safety of all personnal.

c. Coordinate and direct all emergency measures

d. Inform his superiors.

The Health Physicist in case of fire or explosion is responsible for:

a. Detecting spread of contamination, if any. Initiating radiation-contamination surveys if necessary.

b. Advising emergency coordinator as required.

c. Insuring the wearing of necessary protective equipment.

d. Checking personnel for possible contamination and information regarding radiation exposure.

e. Assisting coordinator as required in making a thorough post-emergency evaluation.

f. Initiating personnel decontamination and administering first aid if necessary.

All the other personnel in the area will report to the parking lot area and await instructions.

11.10.4.2 Fires in Low Hazard Area

11.10.4.2.1 Detection

Non-radiation areas are protected by sprinklers. Radiation areas, with the exception of the cells, are protected by heat detector alarms. Manual fire alarm stations are provided in each area.

11.10.4.2.2 Standard Procedure

A cell operator is required to do the following:

a. Sound the alarm, if not already done.

b. Bring the work in the process cell to a point where it is safe to leave if necessary.

c. After putting on respiratory equipment, assist to extinguish fire if nearby.

d. Check operation of ventilation system.

e. Remain in operation area, alert for problems until instructed otherwise.

The emergency coordinator is required to:

a. Determine location of alarm.

b. Don respiratory protective device.

c. Instruct others to extinguish fire or assist as required.

d. Check with Health Physics.

The Health Physics representative must:

a. Don respiratory equipment.

b. Proceed to fire location.

c. Evaluate hazard.

d. Assist as required

Others persons, if in the vicinity of the fire, must sound the alarm, don respiratory equipment and extinguish the fire. If in another location, they should report to the assembly area to be available to assist.

11.11 Storms

11.11.1 Wind Damage

Under normal conditions, the average wind speed in the area does not affect the building ventilation system. However, if wind speeds should increase to such a degree that they cause a perturbation of the system by varying the static pressure of the building, corrective action will be taken when necessary; i.e., supply air will be reduced to increase negative pressure in the cells and dry boxes, open or close doors and/or dampers to rebalance air system in the operating and service areas. Questionable air flow and pressures will be measured with hot wire anemometer, velometer or smoke tubes.

11.11.2 Flooding

The facility is located on a plateau approximately 1900 feet above sea level. As drainage flows away from the site to lower altitudes, the possibility of flood damage within the facility is quite remote.

11.12 Power Failures

Power failures in the past occasionally have occured. When the power fails, an emergency power system is

automatically operated. Transfer from the main source of power to the emergency power system takes place through time delay relays which permit the emergency unit to reach rated speed and voltage in approximately 10 seconds.

CHAPTER 12

SAFETY EVALUATION

12.1 Introduction

The design and operating philosophy of this facility is based on the principle of multiple containment barriers of radioactive materials at all times. In essence, this means that a minimum of two containment structures must fail in order to allow the release of radioactive material to the atmosphere. The criterion of safety emphasized throughout the analysis is reasonable assurance that the general population in areas surrounding the facility and operating personnel will not receive overdoses of radiation as defined by 10CFR20 and the recommendations of the ICRP.

A shielding analysis has been carried out to assure that direct radiation doses to operating personnel do not exceed acceptable limits.

A complete safety evaluation has been performed to determine the radiobiological consequences of accidental activity releases. All cases in which the possibility of primary containment failure exists were analyzed. The results indicate that activity releases due to containment failure are highly improbable. A very conservative approach was assumed in the postulation of a series of failures that might cause the release of

activity from the secondary containment to the surrounding environment or to operating areas of the facility. This approach is emphasized particularly in the examination of the maximum credible accident.

In addition to accidental activity releases, all of the chemical processing steps and other operational procedures have been studied to ensure their safety with respect to operating personnel and the general public.

12.2 Shielding Analysis

An analysis has been made of the shielding requirements for the strontium-90 production process. The effectiveness of the cells and auxiliary process equipment shields for shielding against the maximum calculated radiation intensity has been established.

12.2.1 Cell Walls

12.2.1.1 Dose Rate from Strontium-90

An analysis of the shielding value of the hot cell walls and windows has shown that dose rates are extremely low for the anticipated amounts of strontium-90 to be processed and handled in the cells. Dose rate calculations were for a curie strength of 250,000 curies and two forms (solution and solid titanate). The dose rate varies practically linearly with the activity.

Dose rates were calculated at points located in the front of the cell outside the walls and windows, at a point on top of the cells, at a point in back of the cells outside the cast iron door but inside the isolation room, and at a point in back of the cell outside the isolation room but shielded by the cast iron door only. These points are shown in Figures 12.1 and 12.2 and the dose rates are given in Table 12.1. The results are conservative since they neglect self-absorption, the shielding effect of structural materials, and the effect of any localized shielding which may be used for personnel entry into the cell.

12.2.1.2 Effect of Cerium-144 on Cell Wall Analysis

It is estimated that the Cerium-144 content may be as high as 2 to 3 millicuries per curie of strontium-90. Table 12.2 shows the increase in dose rates for selected situations around the hot cells. It should be noted that the shielding of the cells is still adequate with this amount of cerium.

The significant bremsstrahlung associated with the decay of Cerium-Praseodymium-144 arise from the approximately 3-mev beta particle of Praseodymium-144. In addition, there are high energy decay gammas associated with Praseodymium-144. As a result, the average energy of the gammas for Cerium-Praseodymium-144 is higher than those from Strontium-Yttrium-90. In terms of shielding, this means that the Cerium-Praseodymium-144 gamma rays become relatively more important and contribute an increasing fraction to the total dose rate as shielding thickness is increased.

12.2.2 Feed Storage Tank

The feed storage tank, T-31 and it's shielding, are located in the cell annex of Cell 4. In the determination of the effectiveness of the shielding it was assumed that 750,000 curies, the maximum activity, was distributed uniformly throughout the tank. The points at which the dose rates were determined and the dose rates are shown in Figures 12.3, 12.4 and 12.5. Figure 12.3 is a plan view with the dose rates given for an horizontal plane taken through the middle of the tank. Figure 12.4 and 12.5 are for orthogonal vertical planes.

These tank T-31 dose rate calculations were performed by integrating the Green's function for the dose weighted by the homogeneous source throughout the tank. To accomplish these calculations IBM 7094 Program SPEND was used. Due to the assumptions made and the method of calculation, the calculated dose rates could be high by as much as a factor of two.

Using the maximum possible activity of 750,000 curies, the dose rates are low enough to allow for short periods of work in the vicinity of the tank.

12.2.3 Dose Rates Through the Shine Shield from the Process Box

To determine the amount of radiation from the process box, a point source of 100,000 curies was used. The

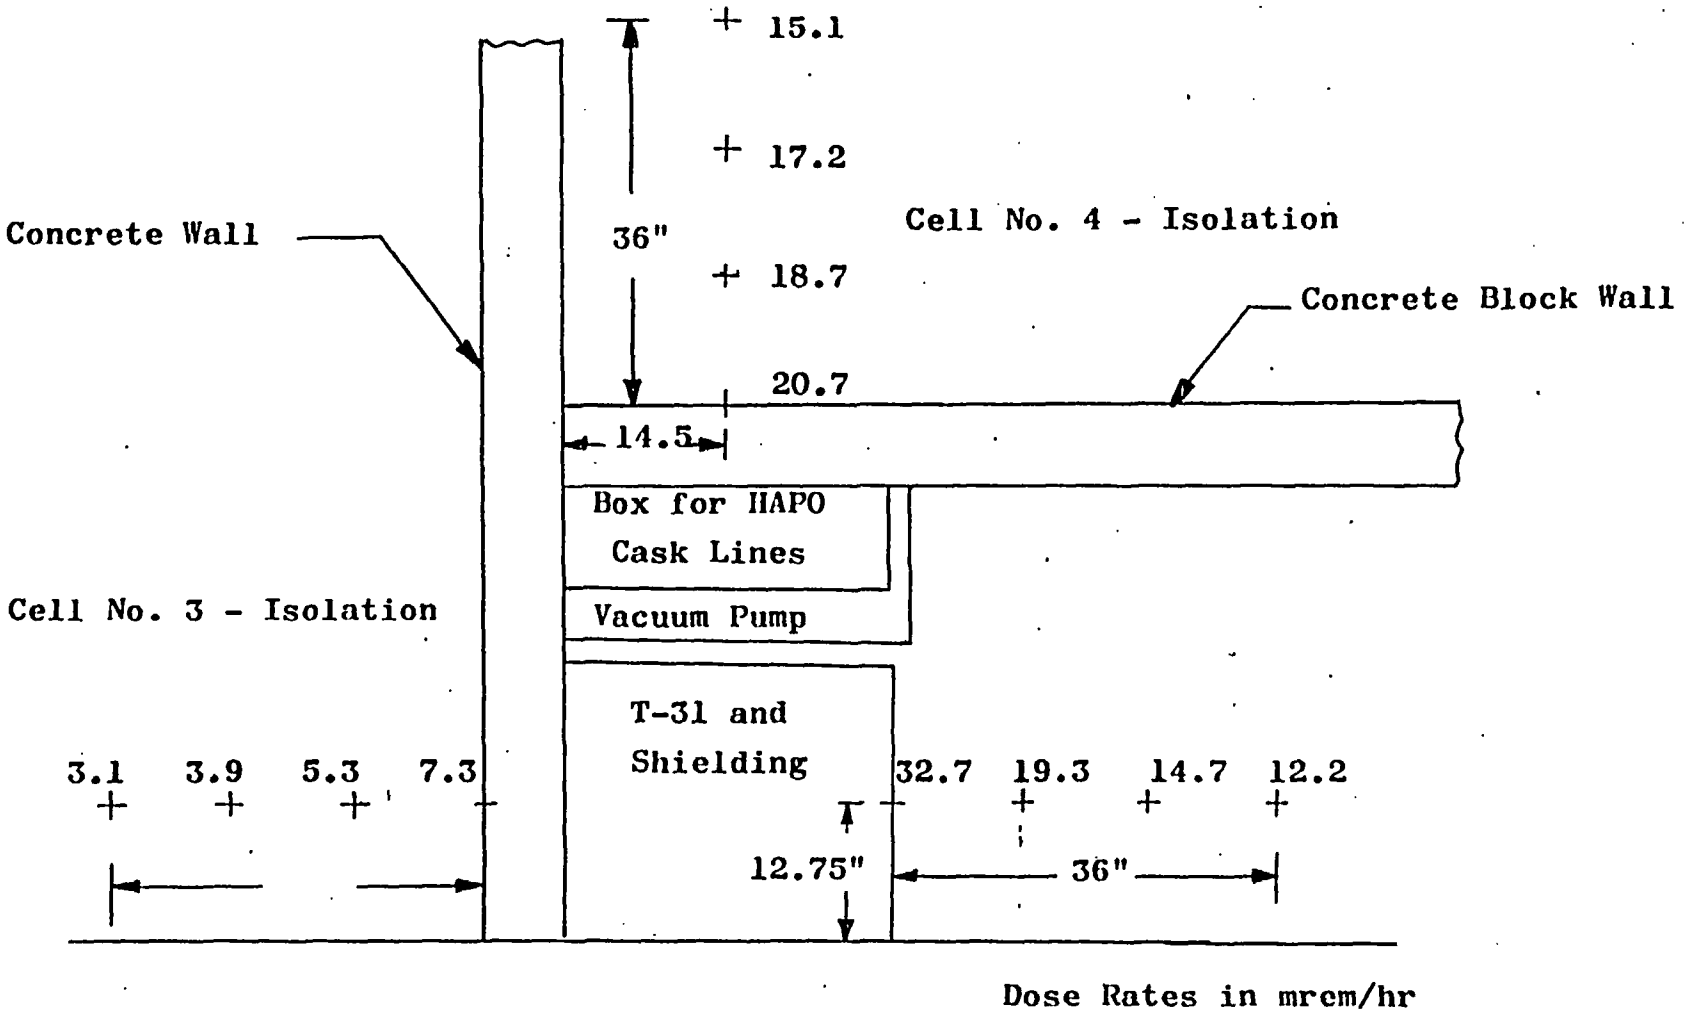

Figure 12.3 Dose Rates from Strontium-90 Storage Tank T-31
Horizontal Plane through Middle of Tank

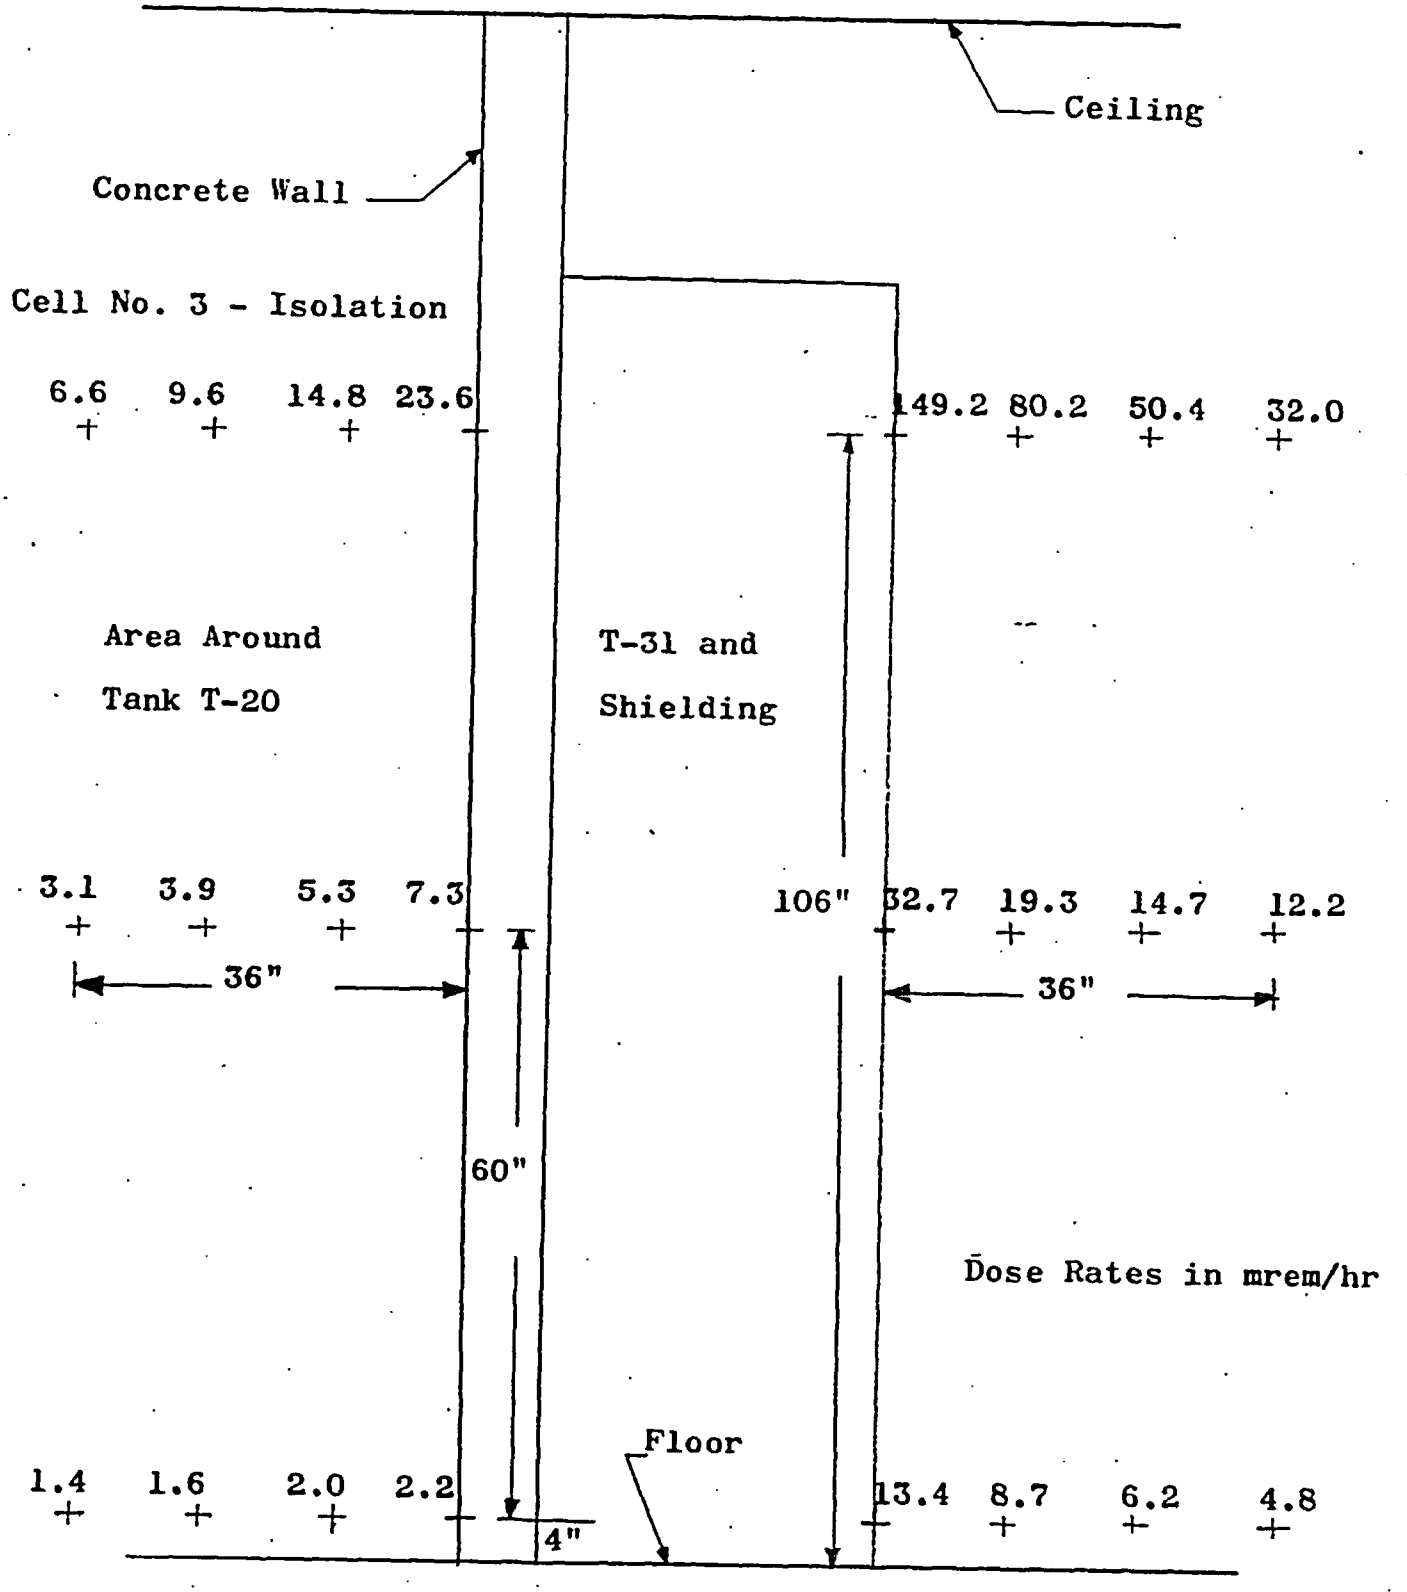

Figure 12.4 Dose Rates from Strontium-90 Storage Tank T-31 Vertical Section Perpendicular to Cell 3 Isolation Room Wall

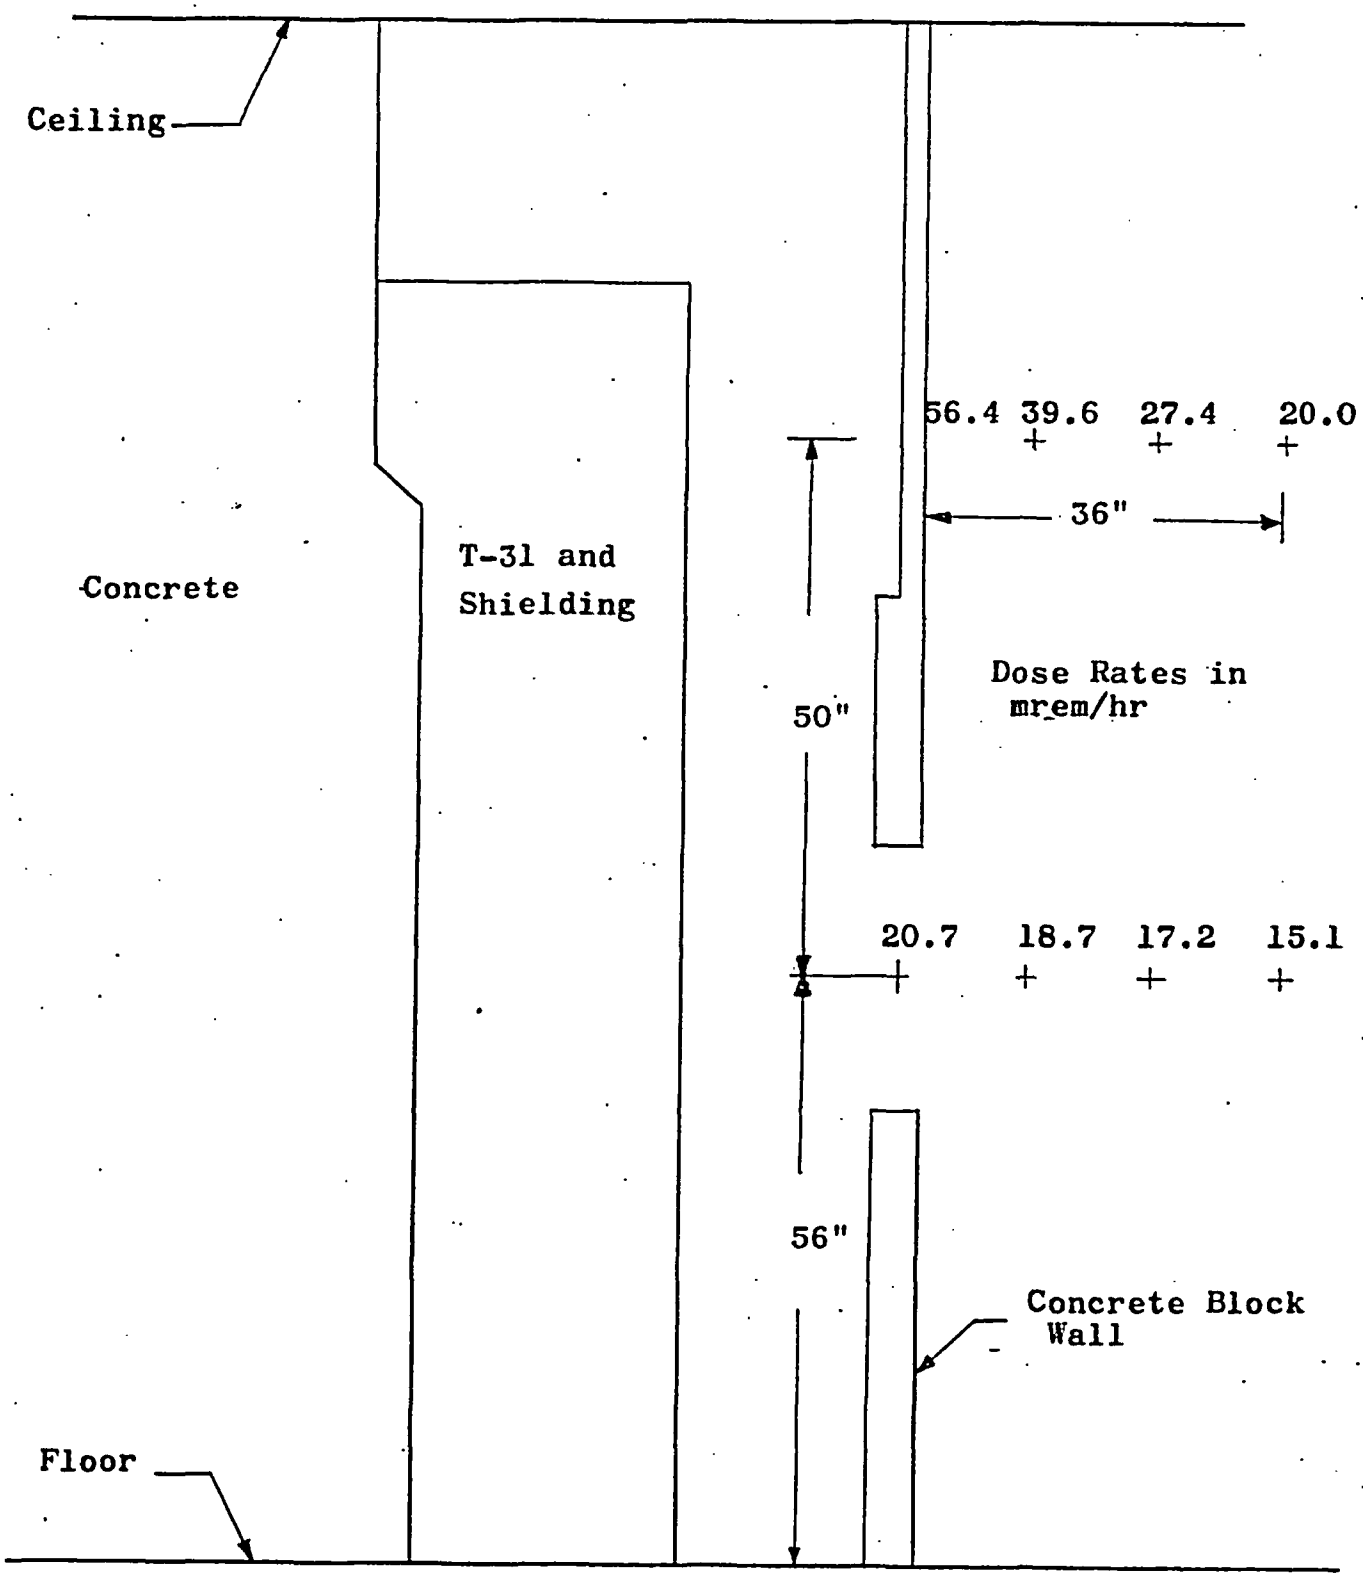

Figure 12.5 Dose Rates from Strontium-90 Storage Tank T-31
Vertical Section Perpendicular to Cell 4 Wall

source was located at a point in the process box closest to the shine shield. Thus the values obtained are conservative.

The calculations were carried out with the 12-inch iron cell door open so that the physical attenuation was due entirely to the shine shield. At a distance of 51 inches from the source the dose rate is 1.66 millrem per hour. Figures 12.6 and 12.7 locate the source and dose points.

It is clear that the shine shield is adequate shielding for the process box. The dose rates are low enough to permit personnel to do necessary maintenance at the closest possible position to the shine shield.

An area which may cause concern is that of the filter plenum. At times when strontium is in the furnace, which is situated in the process box of Cell 4, the dose rate from this source combined with that from tank T-31 and the activity retained by the filter may be high enough to warrant special procedures for changing the filter. Considering only the storage tank T-31 and 25,000 curies in the furnace, dose rates of approximately 25 to 30 millirem per hour are possible.

12.2.4 Temporary Shielding

A curve was prepared for use in estimating temporary shielding for various amounts of strontium-90. Figure 12.8 is a curve of activity versus thickness of lead shielding required to reduce the dose rate to 10 mr/hr at one meter

12.3 Chemical Hazards

12.3.1 Radiolysis of $Sr(NO_3)_2$ Solution

12.3.1.1 Hydrogen Formation

The feed storage tank may contain up to 750 kilocuries of strontium-90 in 250 liters. Assuming conservatively that 100% of the radiation energy emitted is involved in decomposition of the solution, the rate of hydrogen evolution from the solution is calculated to be 78.0 cc/min. (STP). The G value of 0.028 (molecules per 100 electron volts) was calculated from an expression given by Sowden (Reference 12.7) for the effect of high nitrate ion concentrations on the radiolytic formation of hydrogen, assuming a nitrate concentration of 1.27M (0.075M excess HNO_3). The rate of hydrogen evolution varies in inverse fashion with increasing nitrate concentration. For example, increasing nitrate ion molarity of 1.95 (0.77M excess HNO_3) suppresses hydrogen evolution to 16.1 cc/min. (STP). The excess of HNO_3 maintained in the feed tank is normally 0.4 to 0.6M.

In the usual course of operations the 250-liter feed storage tank will have a maximum filling of two-thirds, by transfer from a HAPO-I cask, and will consequently have 500 kilocuries and a void space of about 83 liters. Hydrogen evolution at a proportional rate could theoretically bring the composition of the gas in the void space to the lower flammability limit of

4.1 volume percent in about an hour and to the lower detonation limit of 19% in about five hours. (References 12.8 and 12.9). The opportunity for igniting the gas within the tank is negligible since no access to the tank interior is possible, no electrical connections are made to it and it is not exposed to any flame. In addition, the tank is vented to the process box where dilution occurs before the air is exhausted through the air handling system.

The feed storage tank is air sparged at a rate of about 3 liters/minute when it is first filled, and before any subsequent withdrawals. At this time the hydrogen is diluted and carried away through the air handling system.

If, for some inadvertent or unknown reason, the vent and vacuum connections to the tank should be closed for a substantial period of time, it might first be assumed that the hydrogen evolution would cause pressure build-up in the free volume. Theoretically, it would require about 18 hours to raise the pressure to 15 psig. However, it is more logical to assume that in a sealed vessel, hydrogen produced by radiolysis recombines with the other radiolysis products so that no net hydrogen is produced. Allen (Reference 12.11) has commented on this phenomenon at length. In any event, the tank is capable of withstanding internal pressures of at least 100 psig and has been tested to that figure in conformance with the Uniform Unfired Pressure Vessel Code.

12.3.1.2 Nitrite Formation

Another radiolytic reaction is expected to occur in the storage tank, namely the reduction of nitrate ion to nitrite ion, with attendent consumption of hydrogen ion. The G value depends on the nitrate ion concentration and is computed to be 1.95 for the case at hand (Reference 12.12), giving a maximum nitrite ion formation rate of 3.03 gram-mole/hr. No safety considerations are apparent, in the formation of nitrite ion, since strontium nitrite is reported to exhibit essentially the same solubility as the nitrate and has no unusual chemical properties.

12.3.1.3 Oxygen and Peroxide Formation

As far as can be determined by an examination of the literature the formation of oxygen gas or of hydrogen peroxide should not occur to any significant extent in the feed solution.

12.3.2 Chemical Energy Production

12.3.2.1 Heat of Neutralization of Excess Acid

Excess HNO_3 added during the dissolution step is neutralized during the course of carbonate precipitation in Cell 4. The concentration of the excess acid is measured and will not exceed 1M and is usually held to about 0.5M. If the volume of solution aliquoted for precipitation is 9 liters it may contain 9 moles of excess HNO_3. Based on a heat of

neutralization of 13.1 kcal/mol, 118 kcal may be liberated during the neutralization step. This can produce a temperature rise of about 10°F but cannot result in any excessive release of energy.

12.3.2.2 Heat of Reaction of Carbonate Precipitation

From data readily available on the heats of formation of the various chemical species involved in the reaction by which strontium carbonate is precipitated, it is found that the reaction is slightly endothermic (Reference 12.13):

$$Sr(NO_3)_2(aq) + Na_2CO_3(aq) \rightarrow SrCO_3(s) + 2\ NaNO_3(aq)$$

Heat of formation:	229.82	276.18	291.28	214.66

$$H = +\ .06 \text{ kcal/mole}$$

Since a batch size of 25,000 curies of Sr-90 precipitated at a time amounts to about 40 mol of reactive cations, this reaction is of no great concern from an energy release or absorption point of view. The reaction of the calcium present is ignored for purposes of this study since the amount is small and this reaction also involves only a small quantity of heat. The TiO_2 present at the time of carbonate precipitation does not react chemically with the other reagents present.

12.3.2.3 Stability of $SrCO_3$ - TiO_2 Mixture

The mixture of $SrCO_3$ and TiO_2 which is separated by filtration from its supernatant liquid is permitted to dry

partially by self-heating before it is processed further. The batch generates heat at the rate of 160 watts. This heat is expanded principally in evaporating the water held in the precipitated mixture.

Following evaporation of the water, the temperature of the cake will rise to an equilibrium figure whose value is determined by various factors unless it is placed within a water-cooled receptacle available for that purpose. In no event can the self-heating of the cake cause a temperature rise sufficient to cause reaction between the $SrCO_3$ and TiO_2, since the reaction rate has been conclusively demonstrated to become significant only above 925°C. It is thought that the reaction between $SrCO_3$ and TiO_2 is perhaps endothermic, but the heat of formation of $SrTiO_3$ has not been determined. The experimental evidence shows that the evolution of heat is, at most, quite small. The reaction is consequently not contributory to any significant energy release during the process.

12.3.2.4 Fires

Neither the material being processed nor any of the reagents used are flammable and it has been shown above that energy releases in the process reactions are quite moderate. No open flames are used. The only combustible materials to be found in the process box at any time are the required electric

insulation, manipulator boots, polyethylene reagent bottles and cloth swabs used for minor decontamination. These are present in very small quantities, generally have high ignition temperatures, are non-explosive and even if any of them could become ignited the total energy production is not great.

12.3.3 Radiolysis of Pool Water

The storage of the encapsulated sources in the pool will result in some radiolysis of the pool water. The beta energy of the strontium-90-yttrium-90 chain is entirely dissipated within the capsules, but gamma energy produced as bremsstralung enters the water. In the following calculation, correction has been made for self-absorption within the capsule. A G factor of 0.25 molecules per electron volt has been used.

The total bremsstrahlung energy generated per curie per hour is obtained by integrating the energy yield spectrum:

E	Yield Photons/dis	E	Mev/dis
2.2-1.98	7.42×10^{-7}	2.1	1.56×10^{-6}
1.98-1.76	6.75×10^{-6}	1.87	1.26×10^{-5}
1.76-1.54	2.89×10^{-5}	1.65	4.76×10^{-5}
1.54-1.32	8.51×10^{-5}	1.43	1.22×10^{-4}
1.32-1.10	2.09×10^{-4}	1.21	2.53×10^{-4}
1.10-.88	4.37×10^{-4}	.99	4.32×10^{-4}
.88-.66	8.87×10^{-4}	.77	6.84×10^{-4}
.66-.44	1.82×10^{-3}	.55	1.0×10^{-3}
.44-.22	4.12×10^{-3}	.33	1.36×10^{-3}
.22-0	1.65×10^{-2}	.11	1.81×10^{-3}

$$\int E\nu(E)dE = 5.7 \times 10^{-3} \text{ Mev/dis}$$

For one curie: $2.1 \times 10^{+8}$ Mev/curie sec, or 2.1×10^{14} ev/curie sec

For one megacurie: 2.1×10^{20} ev/curie sec

$$\text{gm moles/sec} = \frac{2.1 \times 10^{20} \text{ ev/sec} \times 0.25 \text{ molecules/ev}}{6.02 \text{ gm moles/molecule}}$$

$$= 8.7 \times 10^{-5} \text{ gm moles/sec or } 8.14 \times 10^{-1} \text{ gm moles/hr}$$

or, 7 liters/hr

This rate of hydrogen generation is not high enough to present a hazard. The pool is covered by an expanded metal cover, and also by a sheet of transparent plastic. The latter is elevated so that air can circulate under it. The air circulation in this area of the facility is good so that there can be no accumulation of hydrogen.

12.4 Transfer Accidents

12.4.1 Cupola Rupture

The purpose of the cupola is to provide secondary containment of the HAPO cask connections during and subsequent to the transferal of the feed solution from the cask to the feed storage tank. The operator, wearing full protective clothing (Section 10.7) and an independent air supply, removes all lines and the thermocouple by working through the glove ports. If the cupola should be torn away during this process, any spilled or otherwise deposited feed solution would remain in the well of the cask. Even though the operator is safe in the absense of the cupola, its presence is justified by the fact that it does, if intact, prevent any release to the surrounding area, that would require cleaning up.

12.4.2 Feedline Breakage

As stated in the process description, subsequent to the connection of all lines and the thermocouple to the HAPO cask, no personnel are in the isolation room. The process from dissolution on is carried out remotely. The strontium solution is vacuum drawn to the feed storage tank through the feed line. Unless the supports fail and the line breaks simultaneously, only a minor spill can occur, the major portion of the solution running back into the cask or being drawn to the feed storage tank. If the feedline should break at the point where it goes into the isolation room wall and if, in addition, the line supports

should fail, allowing the line to fall to the floor, then worst-case conditions would be realized. The greatest length that could extend from the HAPO cask to the floor is 8 feet. The inside diameter of the line is 0.275 inch and the solution concentration is a maximum of about 3 curies/cm^3. Thus a maximum of

$$(\pi r^2 h\ cm^3)(3\ curies/cm^3) = \pi(0.1375)^2(8 \times 12)in^3 \times 16.39\ \frac{cm^3}{in^3}$$

$$\times 3\ curies/cm^3 = 280\ curies$$

is released to the floor of the isolation room. As the process is TV monitored, any such release and its extent could be immediately determined. If the maximum release occurs, water dilution will be necessary before manual clean-up (as described in waste hold tank leak section) is initiated.

12.4.3 Capsule Transfer from Cell 5 Storage to Storage Pool

12.4.3.1 Cask or Capsule Rupture During Transfer from Cell to Pool

During transfer of the cask, on a dolly, the dolly will be pushed and guided by trained operators over a smooth, uninterupted, concrete floor from Cell 5 to the service area.

During transfer of the cask by the 15 ton capacity service area crane, the cask will be suspended not more than 15 feet or less above the service room floor as it moves across the service area to the pool. While all handling and movement will be performed by skilled operators, a human error or

mechanical failure could result in the dropping of the cask in the area between Cell 5 and the pool.

This cask will be constructed with a steel inner and outer jacket. The inner jacket will be at least 1/4 inch thick and be bonded to the lead so that significant deformation cannot occur if the cask is dropped. The cask cover will be secured to the cask body by a steel pin of at least 1/2 inch diameter to prevent disassembly in case of impact. Thus it is considered incredible for a capsule to become dislodged and crushed or significantly deformed by the cask.

Having established the above criteria for the transfer cask, it is apparent that the maximum load on a capsule will be its own impact force. While the cask will be fastened in a manner to preclude disassembly, the components of the cask will probably not be rigidly connected. Each component will react essentially, as an independently impacting body. So, similarly, will the capsules react. This means that except for the differences in material characteristics between the cask and the floor the impact loads on a capsule impacted within the cask would be the same as the impact loads on a capsule dropped independently. In practice, the bottom of the cask will probably be a better energy absorbing medium than the floor, so that a capsule contained in the cask will be subjected to less stress than one dropped separately.

Using $v = \sqrt{2as}$ it is calculated that a capsule dropped from 15 feet will impact with a velocity of 31 ft/sec. The average weight of a powder capsule is about 5.21 pounds so that its kinetic energy at impact is very nearly 80 ft-lb. The lack of engineering data and correlations for the analysis of containers under impulsive loads precludes a detailed analysis of the stress imposed on the capsule for all attitudes of impact. That the capsule will not rupture under 80 ft-lb impact can be inferred, however, from a calculation of the total energy which the outer container can absorb without rupture. This is simply the area under a standard tensile stress-strain diagram for the container material multiplied by the container volume. The area under the stress-strain curve for AISI-316 steel is 47,000 in. lbs/in^3 and the outer container volume is 6.095 in^3. The container should be capable of absorbing up to approximately 20,000 ft-lbs without rupturing. Since the impact energy under question is only 80 ft-lbs it is clear that the capsule would not be ruptured by a 15 foot drop onto a concrete floor.

12.4.3.2 Capsule or Pool Damage by the Cask

Dropping the cask into the pool would impose approximately the same load on the capsules in the cask as dropping on the service room floor and is, therefore, no more hazardous. Dropping of the cask upon capsules already in the pool is not credible since the capsules will be stored around the periphery on three sides of the pool with the fourth side being

kept free of capsules. The cask will always be transferred across this side of the pool.

It has not been possible to determine if a dropped cask would crack the pool floor. Consensus of opinion, based on the pool design, is that it would not. If the floor were to crack, however, it is believed that the resultant leakage rate would be small and, therefore, not represent a hazardous condition.

12.4.3.3 Capsule Melting

The total weight of strontium fuel and steel in each capsule is less than 6 lb. The specific heat of fuel and capsule is approximately 0.12 BTU/lb.°F. The temperature rise, assuming adiabatic conditions would be:

$$t = \frac{7.4 \text{ BTU/min}}{6 \text{ lb} \times 0.12 \text{ BTU/lb°F}} = 10°\text{F/min.}$$

This is well below a rate of rise that could cause thermal shock.

An alternate cask is available in which six capsules may be transferred. The most severe heating will occur with six capsules contained in the cask. The maximum heat output per capsule is 130 watts and the cask will be approximately 10 inches ID by 30 inches OD. If the cask is taken as lead only, the inner surface will be raised only a few degrees Fahrenheit above ambient. Assume only radiation loss of heat by the capsules (conservative, since convection will also remove heat). If one-half the lateral surface of the six capsules is taken as the radiative surface and an emissivity of 0.3 is assumed for

capsule and inner cask surface, the maximum surface temperature achieved on the capsule is less than 100°F. Since this is well below the melting point of stainless steel (2550°F), there is no danger of capsule melting.

12.5 Storage Accidents

12.5.1 Cell 5 Storage

The capsules that are stored in Cell 5 are cooled by the cell air flow. Since there is an auxiliary cell exhaust system, it is not considered credible that the capsules would be without cooling. If the normal exhaust system should fail, it could be repaired while the auxiliary system maintained the air flow.

The analysis of the accidental dropping of a capsule (Paragraph 12.4.3.1) showed that a capsule could not be damaged by a fall from 15 feet so, since the cell has a 12 foot ceiling, a drop in the cell could not damage a capsule.

12.5.2 Pool Storage

12.5.2.1 Capsule Leakage During Storage in the Pool

Every capsule is doubly contained and leak-checked before removal from Cell 5. However, if both the inner liner and outer container of a capsule are damaged during transfer or installation in the pool, a leak could develop. Such a situation is extremely improbable but is remotely credible.

The presence of a breached capsule would be promptly detected during one of the frequent gross beta count

analyses of the pool water and/or as a result of detection by the continuous liquid flow type monitor probe. Furthermore, a device which is capable of locating the leaking capsule is a permanent part of the storage facility. This device consists of a can, open at one end, which fits over the fuel capsule. Flexible tubing, attached to the other end, is connected to a pump which draws water from immediately around the capsule through a liquid flow counter. Available liquid flow counters of the continuously monitoring type are capable of detecting concentrations as low as 10^{-7} µc/cc.

The pool is filled from the 2-inch main pool water supply system. A 2-inch overflow pipe terminates one foot below the top of the pool and connects with the suspect drain system. Thus, it is not possible for any water from the pool to enter uncontrolled drainage or sewage systems.

12.5.2.2 Failure of the Pool Water Circulation System

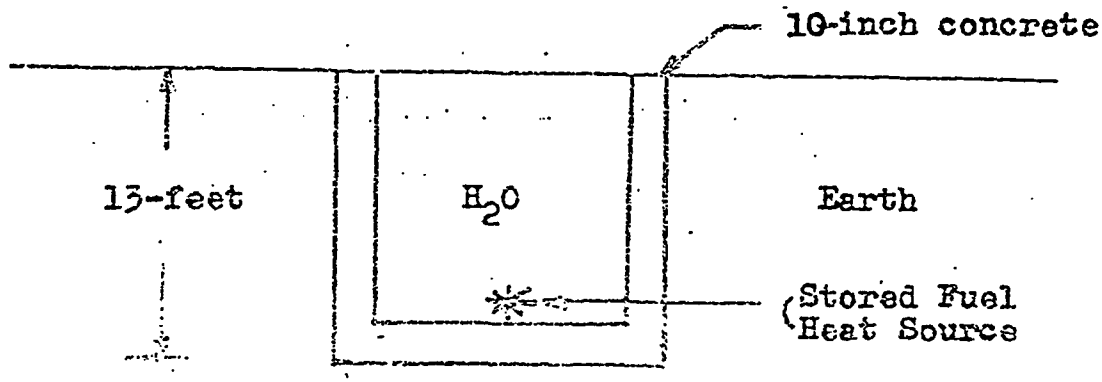
The clean up system for the gamma pool consists of a stainless steel closed circuit system which runs from the gamma pool four and one-half feet underground to a shielded room in the mechanical equipment room. Access to this room is through a separate locked door. The pool water recirculating system is enclosed by three walls of concrete blocks, the building outside wall making up the enclosure. The 3/4-inch plywood top and concrete block walls have a smooth nonporous finish painted with Phenoline 300 or its equivalent. Equipment in the cleanup

room consists of two circulating pumps rated at 5 and 20 gpm and two resin beds and two 10-micron filters in parallel. Each of these resin beds is so designed that the valves may be closed to one bed and the complete filter unit, if necessary, can be removed and replaced. Only the resin may be replaced if desired.

If the water circulation system for the storage pool fails, the temperature of the water will increase, since there will be heat transferred out of the pool through the walls and to the air above the pool, an equilibrium temperature will be reached that depends on the activity stored in it.

The storage pool at Quehanna is 13 feet deep with surface dimensions of 8 x 10 feet. The walls are made of 10 inches of concrete. The stored material acts as a constant heat source to the water. Heat is lost from the water in two ways.

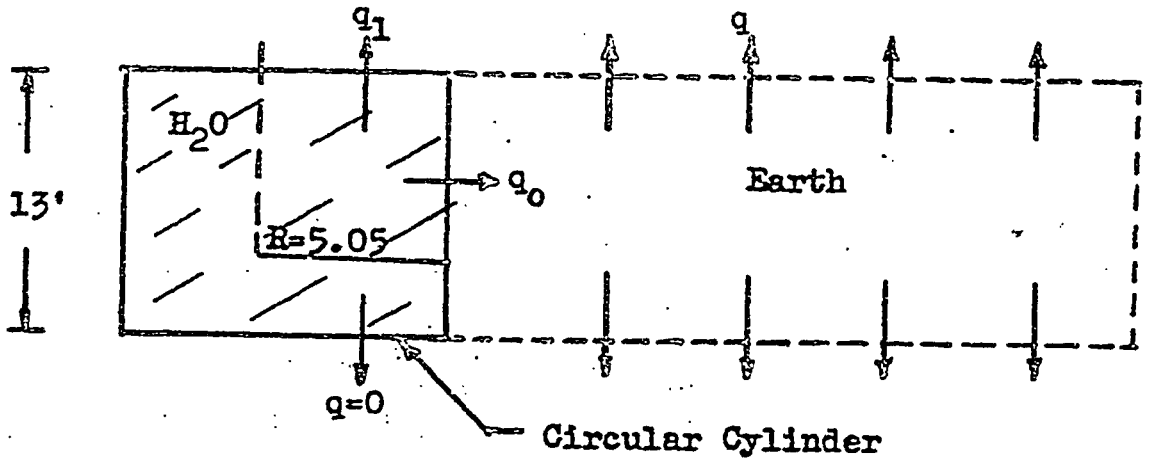
1. Heat is conducted through the concrete walls and into the surrounding earth.
2. Heat is transferred by convection from the upper surface of the water to the air above the pool.



The analytical model chosen to solve the heat transfer problem is that of a circular cylinder. The dimensions of the cylinder are chosen so the surface area of the cylinder is the same as that of the actual pool and the depth is the same.

The assumptions used to simplify the problem are:

1. The air above the pool is still. It is at atmospheric pressure with a temperature of 70°F.
2. Since there will be natural mixing of the heated water, the water is assumed to be the same temperature throughout.
3. No heat is lost through the bottom of the pool.
4. The thermal conductivity of the earth is K = 1.1 BTU/hr ft°F (Reference 12.10). This is the conductivity of the sandstone which is found in the Quehanna area.
5. The cooling affect of the evaporation of water from the surface is neglected.
6. The heat loss through the walls is approximated by calculating the heat loss from an infinitely long fin of earth extending radially from the pool. The fin shape is that of an annular disk.



The results of this calculation are shown in Figure 12.9. It is found that for about 800000 curies stored in the pool the equilibrium temperature reached is 150°F. At this temperature the maximum evaporation rate is about 10 gal/hr. A heat exchanger will prevent the temperature from exceeding 150°F even with 5 megacuries stored in the pool.

A second calculation was made for the rate of evaporation with air circulation over the pool.

The results of the calculations are:

Velocity of Air (ft/min.)	Water Loss (gal/hr.)
0	6.62
10	6.88
60	8.35
120	10.00 = maximum

12.5.2.3 Total Loss of Pool Water

A total loss of pool water, resulting from any sequence of events, is not considered to be credible. The entire water purification and circulation system is in a closed cycle, physically located above the normal water level of the pool. The slow loss of water through a crack in the concrete is

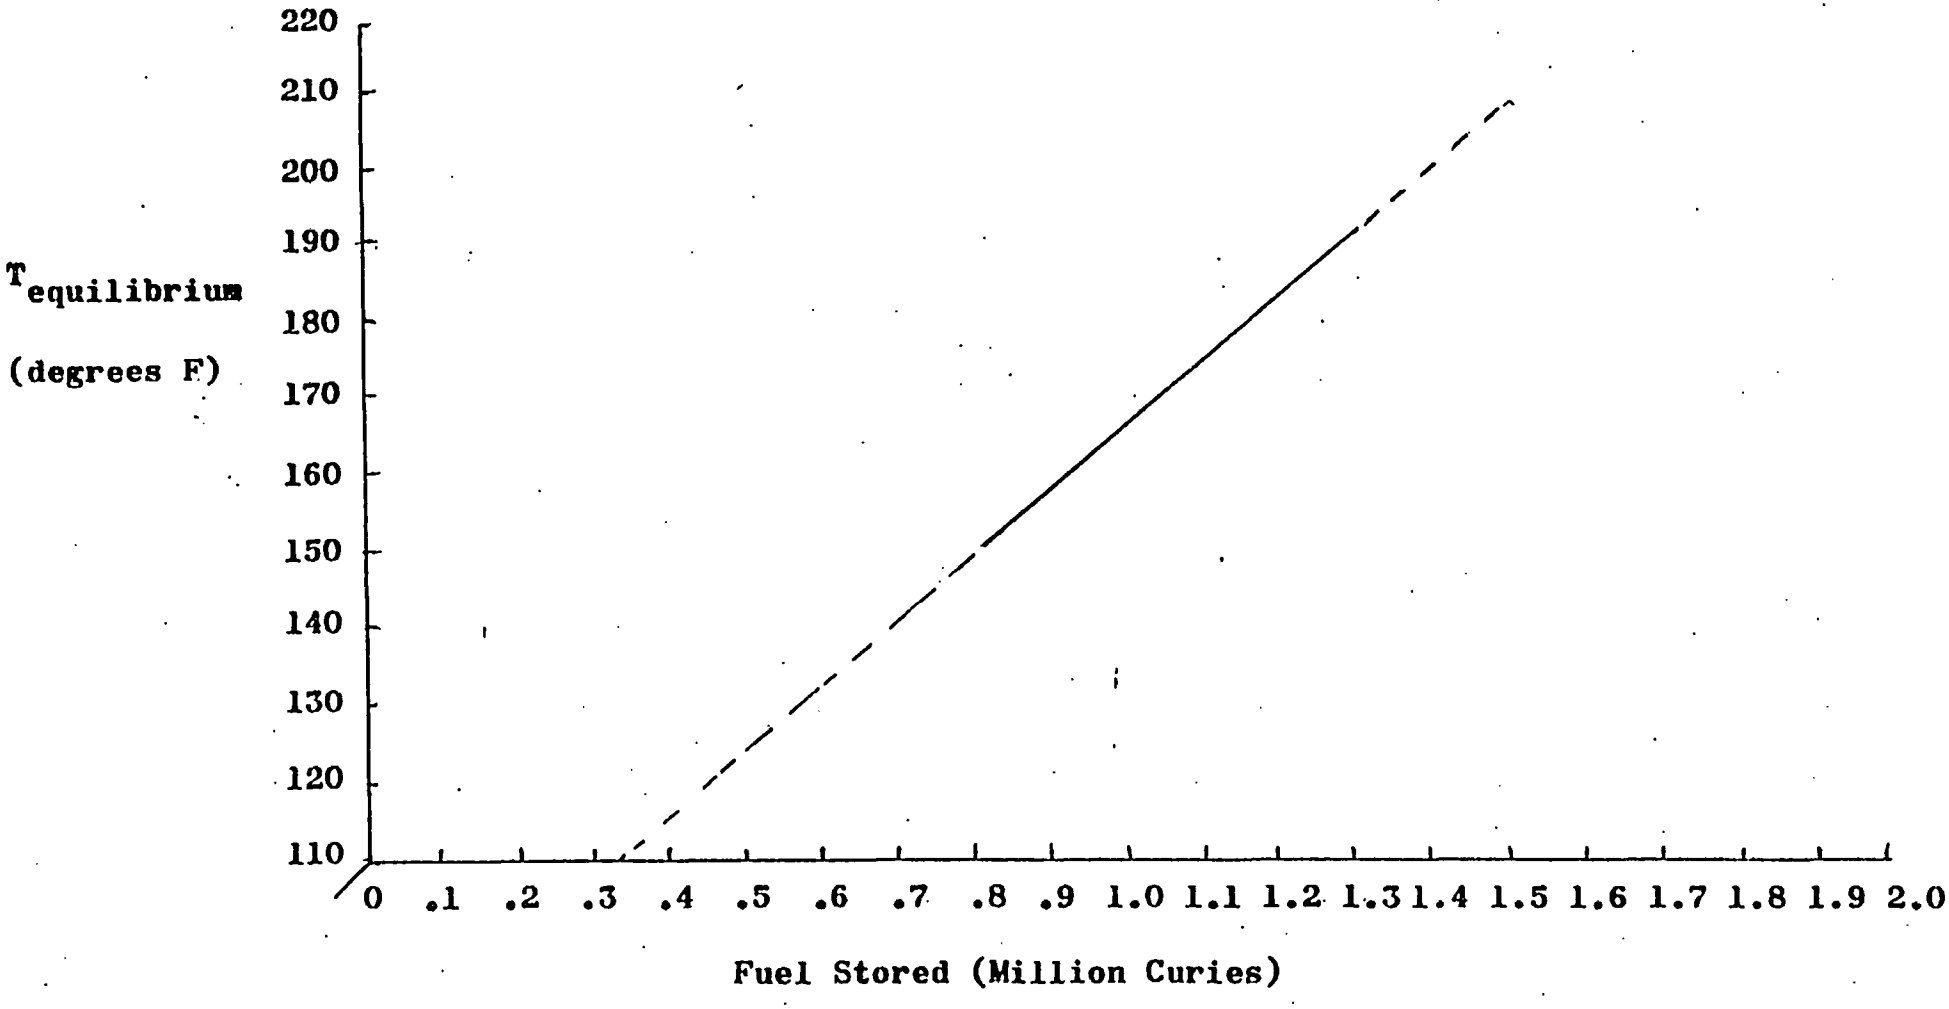


Figure 12.9 Equilibrium Temperature vs. Fuel Stored

possible. The area and the pool are under 24-hour surveillance by facility personnel. In addition, demineralized water is made and is available adjacent to the pool. Thus, the pool water level will be maintained at proper level and immediate response would be given to correction of the source of leak.

12.5.2.4 Accidental Falls into the Pool

The probability of such an accident is extremely remote. A three-foot high concrete rail surrounds the pool and it is covered except during actual transfer and leak testing operations.

12.6 Air Handling Analysis

After considering the possible malfunctions of the ventilation system which might occur during the operation of the plant, the following two cases were taken as representative. They include situations which arise from a malfunction of instruments and the operating error of the personnel.

12.6.1 Instrument Malfunction

In examining the possible ways for a pressure reversal to occur due to instrument malfunction, the following case was considered.

The normal exhaust fan for Cell 4 (E-6) was considered to have failed. This would only present a problem if the differential pressure switch across this fan would malfunction. Normally, the loss of pressure change across the fan would automatically close the damper in the normal cell exhaust

duct, open the damper in the auxiliary cell exhaust duct, start the auxiliary cell exhaust fan and an alarm would signify the stopping of the normal exhaust fan (see Figure 6.2). Also, the loss of air flow in the normal exhaust duct would cause the gravity backflow damper to close in that duct. It was considered that the differential pressure switch failed to acknowlege the loss of pressure change across the normal exhaust fan E-6. The auxiliary cell exhaust system would not come on, nor would the motorized damper in the normal cell exhaust duct close. Also consider that the gravity backflow damper had stuck in the open position. The result of this series of highly unlikely failures of equipment would be that the cell exhaust duct from Cell 4 would be open and no fan would be operating in that duct.

The back pressure from the friction and inertia losses in the stack was calculated to be 0.151 inches of water. This back pressure plus the higher pressure in the exhaust duct on the way to the stack from the other cells would cause a nominal backflow toward Cell 4 along the normal cell exhaust duct. The pressure drops across the two absolute type filters and one roughing filter in series in this duct would reduce the back pressure seen by the cell. The backflow would cause the pressure in Cell 4 to slowly start to rise. The gauges measuring the pressure difference between the cell and the operations area would show the pressure differential reduction and the auxiliary cell exhaust system would be started.

The result would be, even after the highly unlikely series of instrument failures, that the auxiliary cell exhaust system would return the pressure differential to normal with no resulting pressure reversal. The operating personnel would immediately check the normal cell exhaust fan and damper system since, even though the instruments did not show the reduction in pressure differential across the fan, the starting auxiliary exhaust system would indicate that the normal exhaust fan was not in operation.

12.6.2 Operating Personnel Error

In examining the possible hazards created by operator errors, the following case was considered.

To change a manipulator boot the manipulator must be removed from the cell wall. While the manipulator is out of the cell wall there is an 8-inch opening which leads from the operations area into the cell. During a normal boot change, the old boot is left in place while the new boot is pushed through the opening. Therefore the 8-inch opening is covered at the process box end by the old boot. A special tool is used to hold the flat spring (see Figure 9.4) compressed while the new boot is moved through the cell opening. When the new boot is lined up, the old boot is pushed off and the flat spring is released so that the new boot is in place. If the operator should accidently misjudge the alignment or somehow drop the new boot as well as the old boot into the process box, there would

be an open path leading directly into the process box.

The resulting air velocity through this opening was calculated to be over 3800 feet per minute when the cell and process box exhaust systems are in operation. If, for some unlikely reason, both the normal and auxiliary cell exhaust systems should fail leaving only the process box exhaust in operation, the velocity is over 280 feet per minute. These velocities are high enough to insure that no upstream diffusion of contamination could occur.

12.7 Process Vessel Leaks

12.7.1 Feed Storage Tank Leak

The feed storage is located in the cell annex of Cell 4 flush against Cell 3 isolation room wall and Cell 4 wall. The tank is designed with a safety factor of five or more. It is leak tested at a pressure of 100 psi for 4 hours. All seams are Heliarc welded and the chance for a leak is indeed remote. If, however, a leak should occur, in keeping with the practice of double containment, a watertight chamber which is constructed of 1/4-inch stainless steel surrounds the feed storage tank. The stainless steel chamber will have a capacity greater than the feed storage tank. A stainless steel line (normally capped at termination) runs from the bottom of this chamber into the cell. It would be used to carry the spilled feed solution into the cell in the event of a leak. Another line is provided to make possible the washing of the feed storage

tank exterior.

Cooling the liquid presents no problem as the stainless steel cooling coils spiral about the exterior of the tank and are in direct contact with the liquid. If the cooling from one set of coils is insufficient, a second set parallel to the first can be operated in addition. The release of activity-bearing vapor resulting from such an occurrence is the maximum credible accident and is considered later.

12.7.2 Waste Hold Tank

The waste hold tank is located in the isolation room of Cell 3. Before any solution is transferred to the waste hold tank it is sampled and tested to be sure the activity is low (see Paragraph 3.1.4). This assures that a minimum of fuel material is lost to waste, and that the activity level of the waste hold tank is low.

The waste hold tank is made of 1/4 inch stainless steel and all seams are Heliarc welded. The tank has been pressure tested to 100 psi for 4 hours.

The waste contained in the tank is of low enough activity to allow manual clean-up in case of a release. The operator would don full protective clothing as described in Section 10.7 and mop up the spill using long-handled tongs and an absorbent material. The contaminated absorber is deposited in a shielded container and the container is stored in the waste storage building. As in the case in any type of accident,

the area is sealed off and the Health Physicist conducts a survey to determine the extent of the contamination.

12.7.3 In Cell Tank Leaks

Cell 4 contains the filtrate tank, capacity 75 liters; the vacuum surge tank, 50 liters; the metering tank, 5 liters; and the precipitation vessel, 50 liters. The latter two are in the process box. All of these tanks are constructed of stainless steel, are Heliarc welded and have been tested to 100 psi for four hours. Leakage of any of these is improbable but in case it should take place the shielding due to the cell wall prevents any direct radiation hazard. Clean-up, decontamination and repair within the process box would be carried out by use of the manipulators. The tanks that are not in the process box cannot be reached by the manipulators so repair would be carried out by other remote means.

12.7.4 Hydraulic Oil Leakage

The hydraulic fluid used in the press is Monsanto Pydraul which is composed of phosphate esters and chlorinated hydrocarbons. These liquids have open cup flash point temperatures of approximately 470°C and fire point temperatures of 675 - 725°C. Therefore, in order for the fluid to flash, it must be completely vaporized and must be subjected to a temperature of at least 700°C.

If a minute hole should form in the hydraulic pressure line during the power stroke of the press, it is conceivable

that a portion of the hydraulic fluid could be sprayed out in a vaporized mist. The furnace is the only object in the process box which will even approach the required temperature for flashing the oil. The furnace is surrounded on five sides with panel coil coolers so that the only point of access for oil spray would be the 13-inch high cut out on one panel which is used for the electrical connections for the furnace. However, this area is protected since the hydraulic lines, which are designed with a high margin of safety, enter the 4A section of the process box on the side away from the furnace. The placement of these lines is such that should the line break or spring a small high velocity leak at the weakest point, the connector, the precipitation tank (T-33) would be between the break and the exposed portion of the furnace. For the above reasons the burning of the hydraulic fluid in the process box is not considered to be credible.

12.8 Activity Releases

12.8.1 General

12.8.1.1 Meteorological Models

Sutton's diffusion equations (Reference 12.1) have been used in previous analyses of potential release hazards for the Quehanna site (References 12.2, 12.3) and their use is continued in this study.

The equation for the concentration of a radioactive plume for a continuous point source release is

$$X = \frac{2Q}{\pi u C_y C_z d^{2-n}} \exp\left[-\frac{1}{d^{2-n}}\left(\frac{y^2}{C_y^2} + \frac{z^2}{C_z^2}\right)\right]$$

where

X = cloud concentration at ground level curie/meter^3, equivalent to μc/cc)

Q = activity release (curie/sec)

C_y = cross-wind diffusion coefficient (meters$^{n/2}$)

C_z = vertical diffusion coefficient (meters$^{n/2}$)

u = wind velocity (meters/sec)

d = distance from release point (meters)

n = atmospheric stability parameter

y = crosswind distance from centerline of cloud (meters)

z = vertical distance from ground to centerline of cloud (meters)

Calculations are usually made for ground level under the centerline of the cloud in which case the y^2/C_y^2 term in the exponential drops out.

Two meteorological situations shown in Chapter 2 to be appropriate to the site have been examined. The first of these which tends to prevail during the day is a neutral condition with approximately adiabatic lapse rate. The second which occurs frequently at night, and in the early morning, is a stable inversion condition. The values of the parameters as used for the two models are:

Parameter	Model	
	Neutral	Inversion
C_y	0.40	0.40
C_z	0.40	0.05
n	0.25	0.55
u	5	3

It has been assumed that any discharge to the environment takes place from the stack which has a height of 15.25 meters (50 ft); consequently this value has been used for z.

12.8.1.2 Inhalation Doses

In an airborne release of radiostrontium the principal dose to a receptor in the cloud path is incurred by inhalation. The activity inhaled is calculated directly.

$$I = XBt$$

where

I = activity inhaled (microcuries)

B = breathing rate (cc/second)

t = exposure time (seconds)

It is assumed that the "standard man" inhales 20,000 liters (2.0×10^7 cc) of air in 24 hours. The average breathing rate is consequently 232 cc/sec. However, it is usually assumed that half of the 20,000 liters is inhaled during the more active 8 hours of the day. The breathing rate during this period is consequently 347 cc/sec (Reference 12.4).

The most significant assessment of the potential radiation hazard from inhalation is obtained by a calculation of the integrated lifetime dose to the critical organ accruing from the activity inhaled. This may be calculated by the method proposed by Burnett (Reference 12.5). The applicable equation is:

$$D' = \frac{73.8\, f_a \Sigma EFE(RBE)n\, T_E}{m}$$

D' = lifetime dose for activity inhaled, (rem/μc)

f_a = fraction of activity inhaled that remains in the critical organ

Σ FE(RBE)n = energy per disintegration delivered to the critical organ, considering the relative biological effectiveness (RBE) of the radiation, and n the relative damage factor for nuclides deposited in the bone (Mev).

T_E = effective half life of the activity in the critical organ (days)

m = mass of the critical organ (grams)

For the inhalation of strontium-90 a distinction should be made between soluble and insoluble forms. The bone is the critical organ for the soluble form and the effective halflife is long. For the insoluble form the lung is the critical organ and the residence time of the activity is relatively short. In the subsequent calculations the values used for the parameters for strontium-90 with its daughter product, yttrium-90, are given below (from Reference 12.4).

Parameter	Insoluble	Soluble
f_a	0.12	0.12
Σ FE(RBE)n	1.1	
T_E	120	6.4×10^3
Critical organ	Lung	Bone (including marrow)
Mass	1000	10000
D' rem/μc	1.18	31.1

12.8.1.3 Areas of Potential Exposures

Calculations have been made for the two selected meteorological models of the plume concentration, activity inhaled and integrated lifetime dose for three distances from the Radioisotope Pilot Plant. The first of these, 4800 meters, is the approximate distance to the nearest point on the perimeter of the exclusion area. This is a point not easily accessible and is not normally occupied; it may be visited occasionally by hunters in season. The nearest approach of unrestricted roads is about 8000 meters. The nearest occupied village or town, Sinnemahoning, is distant about 16,000 meters.

12.8.2 Releases to the Environment

12.8.2.1 Maximum Credible Accident

It is assumed that in the future the Radioisotopes Pilot Plant will receive shipments in the HAPO I cask of 500 kilocuries of Strontium-90 and that up to 750 kilocuries may be held in the feed storage tank. This tank is located in a stainless steel chamber in the cell annex of Cell 4. Refer to Chapter 3 and the detached drawings. This tank is made of stainless steel and has fittings and connecting plumbing for connection to the HAPO Cask and to the metering vessel. A rupture of the feed storage tank permitting a large quantity of the strontium nitrate solution to leak into the stainless steel chamger is highly improbable but will be considered to be credible. The strontium nitrate in solution is not volatile. It is

thought that the dual set of cooling coils is sufficient to maintain the feed solution temperature below boiling. But it is assumed that with boiling due to self-heating a fraction of the activity becomes airborne in aerosol form. This fraction is pessimistically assumed to be 0.1%; thus it is postulated that 750 curies can be released. If there should be a failure of one roughing filter and three absolute type filters this activity could be released into the ventilation system and discharged through the stack. It is estimated that there is essentially a complete change of air in the building in about 13 minutes. The rate of release of activity to the environment is assumed to be a continuous uniform release of the 750 curies in 780 seconds, or Q = 0.962 curie/sec.

Thus the maximum credible accident is postulated to be the result of six sequential or simultaneous and scarcely related accidents of varying credibility.

The plume concentrations, activity inhaled and lifetime dose for various distances and the two selected meteorological models are presented in the following table. The greatest dose received, that at 4800 meters under inversion conditions, is 187 rems. This is, of course, a significant radiation dose, but it should be emphasized that this is the total integrated dose received over many years. The

	NEUTRAL CONDITIONS			INVERSION CONDITIONS		
Distance	Plume Conc.	Activity Inhaled	Lifetime Dose	Plume Conc.	Activity Inhaled	Lifetime Dose
d	X	I		X	I	
meters	μc/cc	μc	rem	μc/cc	μc	rem
4800	2.76×10^{-7}	5.05×10^{-2}	1.57	3.29×10^{-5}	6.01	187
8000	1.130×10^{-7}	2.04×10^{-2}	0.635	1.960×10^{-5}	3.54	110
16000	3.37×10^{-8}	6.09×10^{-3}	0.19	8.18×10^{-6}	1.48	46

dose received during the first year is 3.95% of the total, or 7.4 rem, and this quantity decreases progressively each year. It is not expected that clinical symptons would ever be observed in an individual with this exposure.

It should be emphasized that if even one absolute-type filter in the system remained inviolate the plume concentrations at all points would be decreased by a factor of at least 100.

12.8.2.2 Other Accidents

It is assumed that the largest quantity of the strontium nitrate that will be withdrawn from the feed storage tank for batch processing is 25,000 curies. This quantity will be measured in the metering tank and transferred to the process vessels. These transfers are by suction so that any failures due to line leakage or rupture would release only minimal quantities of liquid. After transfer to the process cess vessel there is multiple containment, i.e. the process vessel, process box and cell. It is difficult to conceive of any accident in the processing of the material whereby any large fraction of the activity in the solution could become airborne. For release to the environment there would have to be simultaneous or sequential failure of four absolute type filters. Even if there could be release of as much as 1% of the material, the activity released would be 250 curies and the consequences would be less severe than for the maximum credible accident examined above.

12.8.3 Releases Within the Building

12.8.3.1 General Consideration

The greatest potential hazard to the operating personnel of the Pilot Plant arises from accidents that might release airborne particulate material into the operations area. The situation that appears to be credible is the rupture of a manipulator boot. This hypothetical accident will be discussed in the following analysis.

It is assumed that the largest quantity of strontium titanate powder (or other fuel form) that may be in process in the process box 4A at one time is 150,000 curies. Of this quantity not more than 50,000 curies will be in a loose form subject to becoming airborne. The remainder will have been pelletized, or at least compressed in the way of producing a pellet.

The alundum filter crucible serves as the container in the furnace so that the only pouring of dry powder is into the pellet press.

It is extremely difficult to make a estimate of the quantity of dry powder that could become airborne in the worst circumstances. Various approaches consider the mass concentration of known aerosols and the ratio of exposed surface to the mass of the powder. Postulation of 0.1% as the maximum quantity to become airborne appears to be highly pessimistic. Thus if 50 curies become airborne in process box 4A that has a volume of 9.15m^3 (323 ft^3) the concentration is 5.46 uc/cc.

12.8.3.2 Rupture of Manipulator Boot

A 1/2 inch annular gap exists between the manipulator support tube and the device which clamps the manipulator boot to the wall of the process box. This gap permits the boot to breathe cell air internally as the manipulator is moved in and out. If the pressure in the boot, or in the process box if the boot is ruptured, is considered as rising above the cell pressure, than air is expelled through the gap into the cell.

If a manipulator boot is torn, it is conceivable that, if the manipulator is pushed rapidly into the box, the boot will be filled to some extent with contaminated air from the box, although in practice most of this air will come from the air at higher pressure in the cell. If the manipulator is now withdrawn rapidly, portions of the contaminated air will be expelled into the cell and into the operating area, and a portion will be returned to the box. For the purposes of this analysis, the worst possible case is assumed: the boot is filled only with contaminated air and, once filled, the boot expels the contaminated air only to the cell and operating area. The largest boot employed varies uniformly in average diameter from 10 inches to 4 inches and has a maximum working stroke of 45 inches. It encloses a manipulator arm 4 inches in diameter. Thus, the maximum volume of air pumped is 0.74 $ft.^3$ Based on the steady state flow rate figures computed on the basis of relative opening areas, about 90% of this will flow into the cell

and 10% into the operating area if the manipulator can be moved quickly enough to raise the pressure in the boot to greater than the operating area pressure. This would be almost impossible to achieve in practice, but again for the purposes of the analysis it is assumed to occur. Therefore, 0.074 ft^3 of air would be expelled into the operating area. This 0.074 ft^3, or 2100 cc would contain 1.15×10^4 microcuries. If it is assumed that this activity becomes uniformly dispersed through the volume of the operating area, 18,930 ft^3 or 536 m^3, the concentration becomes 2.24×10^{-5} μc/cc. This is a factor of 4500 times the occupational MPC for insoluble strontium-90. The area monitoring system is capable of detecting levels of the order of the MPC in about one or two minutes, and thus the release of the stated amount of activity would be detected almost immediately, the alarm would be sounded and face masks would be donned. If it is further assumed that the cell operators would breathe the contaminated air for 20 seconds at the 347 cc/sec rate, before the alarm is sounded, the activity inhaled is 0.155 microcuries. The corresponding lifetime dose due to strontium-90 in the insoluble form is 0.185 rem. In contrast to the inhalation of the soluble form, as previously discussed, this dose would be received substantially in the first year. Even if the dispersion of the activity is only into one-tenth of the volume of the operating room, the situation is still tolerable. If this postulated dry release were

of a soluble form, the corresponding lifetime dose would be about 4.8 rem.

PREFACE

R4

This report consists of a consolidation of relevant material originally submitted by Teledyne Energy Systems (TES) over the period August 10, 1971 through January 19, 1972 for purposes of obtaining a transport license for the SENTINEL-100 F Radioisotope Thermoelectric Generator (RTG). By this submittal, TES requests an extension of Certificate of Compliance No. 5862 for transport of the SENTINEL-100F unit.

This consolidated report was prepared in accordance with current U. S. Nuclear Regulatory Commission requirements for a single consolidated report. The information contained herein is that originally submitted over the above cited time froma (1971-1972) which addresses the specific requirements for the transport package of that period. No new analysis is presented. Text added in this issue (designated R4), including this preface, is provided only for purposes of explanation or clarification.

References on the current Certificate of Compliances (dated September 6, 1983) are as follows.

Isotopes, Inc., application dated August 10, 1971. Supplements dated:

a. September 24, 1971
b. October 22, 1971
c. November 30, 1971
d. December 20, 1971
e. January 19, 1972

Supplements (a) and (b) provided revised and additional structural analyses. These revisions are indicated by designations R1, R2, and R3 in the text of the report. In particular, Appendix C provides additional analysis requested by the licensing agency regarding loading of the bolts which attach the shield lid to the body of the biological shield given impact from the 30 foot drop. The analysis is provided to show that the heat source (consisting of the fuel capsule, shield body and lid) will remain intact under this environment. An explanatory note (R4) has been added to this appendix.

Supplements (c), (d) and (e) provide additional thermal information. TES documents related to the original licensing effort indicate that the licensing agency intended to have a third agency (ORNL) conduct separate thermal response analysis for the standard fire. Apparently, the additional thermal information of these supplements was provided in support of this intent. All relevent information in these supplements along with the letter requesting the information have been added to Appendix B of this report. Supplement (d) included a copy of the users manual for the thermal analyzer program used by TES for the thermal analysis reported in Appendix D - namely: INSD-3084, "User's Manual for the Thermal Analyzer Program TAP-3," compiled and edited by R. Hannah, November 1971, Teledyne Isotopes. This 55 page report has not been included with this submittal. The report is available at TES and may be furnished on request.

Construction drawings which define the transport package (as listed on the current Certificate of Compliance) have been included with the report. The included drawings are listed in Appendix D.

To reiterate, the current version of the report consists of a complilation of relevant information originally submitted over the period August 10, 1971 through January 19, 1972. Editorial remarks have been included for clarification. No new analysis is presented. The report addresses the USAEC, IAEA and DOT regulations which were in effect in the late 1971, early 1972 time period for transport of a Type B ( ) package. These conditions and requirements are summarized in the body of the report.

I. INTRODUCTION

The objective of this report is to substantiate the safety aspect of possessing and transporting a designated SENTINEL 100F Terrestrial Radioisotopic powered generator. The approach used to achieve the above objective was initiated with the listing of the safety design criteria as given in Chapter II. This is followed by a general description of the SENTINEL generator and a more detail description of the major components. The interstate regulations and conditions, dictated by the United States Atomic Energy Commission Title 10 and the Federal Register Title 49, which must be satisfied are delineated in Chapter IV. The response of the SENTINEL system (the generator and shipping pallet and/or the fuel capsule) to these requirements and conditions is given in Chapter V.

The regulations and conditions regarding the international transport of the SENTINEL generator were taken from IAEA Safety Series 6 and are discussed in Chapter VI along with the systems response to these additional requirements. Chapter VII summarizes the conclusions reached as a result of this study. Some analyses were conducted which were not required to satisfy any of the regulations or conditions but were made available as supplemental support data. The results obtained from these analyses can be found in Chapter VIII. The details of the structural analyses and thermal analyses are presented in Appendix A and B, respectively.

II. DESIGN CRITERIA

Safety design criteria were established for the operation, storage and transport of the SENTINEL 100F generator. These design criteria to which the generator package or fuel capsule (where specified) were designed are as follows:

(1) Ambient air temperature -40° F to + 130° F.

(2) The fuel capsule shall be capable of sustaining a hydrostatic pressure of 14,500 psi.

(3) Any combination of natural atmospheric pressure and humidity.

(4) The generator housing must have the structural capacity to sustain a seawater pressure at a depth of 2000 feet.

(5) The requirements imposed by U. S. A. E. C. Title 10 and D. O. T. Title 49.

(6) Certification of conformance with applicable requirements of IAEA Safety Series 6.

III. GENERATOR DESCRIPTION

The SENTINEL 100F radioisotopic powered generator is shown in the cutaway sketch in Figure III-1. This design is basically an enlarged version of the SENTINEL 25F with minor modifications. The minor modifications consist of a larger size, a different material for the retaining ring (Inconel) and the addition of a load plate under the tungsten biological shield.

The SENTINEL 100F, as shown in Figure III-1, is 45.5 inches in height and has a base diameter of 24.5 inches (not including the mounting pads). The generator weighs approximately 2600 pounds. Details of the generator can be found on the top assembly drawing (Reference 1). The strontium 90 titanate pellets are housed in a stainless steel liner. The liner is contained by the fuel capsule which provides a positive seal. The fuel capsule is inserted into the tungsten biological shield and the shield plug is bolted into place. The load plate distributes the weight of the tungsten shield over the Min-K 1301 thermal insulation and the load bearing Glasrock. The tungsten shield is held in the horizontal position by the Min-K which is sized to fit within the aluminum housing. The retaining ring is used to preload the Min-K and dampen any vibration loads.

The generator is bolted to the pallet for transportation using four 3/4-inch bolts. A cage is provided which fits over the generator and attaches to the pallet. The cage precludes physical contact with the generator during transportation and storage. It is not required to meet structural requirements since safe transport is not dependent on the integrity of the cage.

13. Thermal Insulation (Min-K 1301)
14. Load Bearing Insulation (Glasrock)
15. Load Plate - Inconel

FIGURE III-1, SENTINEL 100F GENERATOR

A. FUEL CAPSULE

The fuel capsule consists of a liner and strength member which were designed to contain the strontium 90 titanate fuel form under normal operational and specified accident conditions. The fuel capsule assembly along with dimensions are shown on Figure III-2. Details of the capsule assembly and components can be seen in Reference 2.

The liner, which houses the strontium fuel, is constructed from stainless steel tubing. The sole purpose of the liner is to facilitate handling of the fuel and may be eliminated at the discretion of the fueling facility. No credit is taken for any additional protection offered by the liner.

The fuel capsule structural member which houses the liner is machined out of bar stock. The liner is loaded into the fuel capsule and the cap is fusion-welded to give a positive seal. The fuel capsule material is Hastelloy C, Hastelloy C-276, or Uniloy HC to material specification AMS-5750. The details of the fuel, materials and assembly are covered in the SENTINEL 100 fuel and encapsulation specification, (Reference 3).

B. HEAT SOURCE

The heat source consists of the fuel, fuel capsule and a tungsten biological shield. The heat source measures 13.837 inches in diameter and has a length of 19.705 inches. The tungsten biological shield is given a hard chromium plating (4 - 6 mils thick) using a dip process prior to assembly. After the fuel capsule is inserted into the biological shield, the shield plug is put in place and securely fastened to the shield housing

FIGURE WITHHELD UNDER 10 CFR 2.390

FIGURE III-2, FUEL CAPSULE ASSEMBLY

INSD-3080

with 3-1/2-20 UNF bolts (A-286) steel. The purpose of the tungsten shield is to provide uniform heat distribution and the radiation shielding required to meet the radiation safety standards. Details of the biological shield are shown in Reference 4.

C. GENERATOR HOUSING

The 6061 aluminum housing (T6 condition) forms the outer protective shell of the generator. Prior to the generator assembly the housing, heat sink and finned head are anodized and the housing and heat sink are finished with epoxy paint. The base of the generator housing has four aluminum 6061-T6 mounting pads for attachment to the shipping pallet.

D. SHIPPING PALLET AND CAGE

The shipping pallet used for the SENTINEL 100F is the same as was used previously with generators weighing approximately 4000 pounds. The pallet overall dimensions are 43 inches by 50.76 inches and is constructed from square structural steel tubing. Each of four bolts which attach the generator to the pallet is rated for 33,730 pounds tensile yield and 33,150 pounds single shear. Details of the shipping pallet can be found in Reference 5.

The shipping cage fits over the generator and assures physical separation from the generator. The shipping cage frame is constructed from 2 by 4 inch, No. 1 fir or pine. Wire mesh screen (2 by 2 inch) is attached

to the frame to prevent access to the generator. The base of the cage measures approximately 48 by 48 inches and has a height of 51 inches. A detailed description of the shipping cage can be found in Reference 6.

Specifically, use of the shipping cage provides a package which limits the exterior surface temperatures --- see Section IV, page 17. Its use is only required when the package is shipped as general cargo. R4

IV. INTERSTATE SHIPPING SAFETY STANDARDS

To transport the SENTINEL 100F specific conditions and requirements have to be satisfied. The SENTINEL 100F is considered a type B package and falls under the Group II classification as a special form material. The conditions and requirements the package must satisfy are covered by the following documents.

(1) Title 49 Code of Federal Register

(2) Title 10 Code of Federal Regulations

(3) International Atomic Energy Agency Safety Series 6

Covered in these documents are the normal transport conditions, special form requirements, shielding standards and hypothetical accident conditions. A study was made of the specific conditions which must be satisfied. Those which were found to be the governing cases or more severe events were selected for evaluation and are shown in Table IV-1.

TABLE IV-1, CONDITIONS OF TRANSPORT

Environment	Post Test Conditions
A. Normal Transport Conditions (Type B Package)	
1. Direct sunlight at an ambient temperature of 130°F in still air. 2. Cold - An ambient temperature of -40°F in still air and shade. 3. Pressure - Atmospheric pressure of 0.5 times standard atmospheric pressure. 4. Vibration - Vibration normally incident to transportation. 5. Water Spray - Keep entire surface (except bottom) wet for a 30 minute period. 6. Drop Test - 4 foot drop onto an unyielding surface at package critical angle. 7. Penetration - 40 inch drop of a 1-1/2 inch diameter steel cylinder weighing 13 pounds. Long axis of cylinder is perpendicular to the most vulnerable part of package. 8. Compression - A compression load equal to 5 times the package weight or 2 psi times the maximum horizontal cross section, whichever is greater. Load is applied at top and bottom of package in normal shipping position for 24 hours. 9. Meet the hypothetical accident conditions.	1. The reduction of shielding would not be enough to increase the radiation dose rate at 3 feet from the external surface of the package to more than 1,000 millirem per hour. 2. No radioactive material would be released from packages containing Type B quantities of radioactive material. The allowable release of radioactivity from packages containing large quantities of radioactive material is limited to gases and contaminated coolant containing total radioactivity of the package contents nor 0.10 curie of Group I radionuclides, 0.5 curie of Group II radionuclides, and 10 curies of Groups III and IV radionuclides, except that for inert gases the limit is 1,000 curies.
B. Hypothetical Accident Conditions	
1. Drop test - 30 foot drop onto unyielding surface at critical angle. 2. Puncture - 40 inch drop at critical angle onto vertical cylinder = 8 inches long, 6 inches in diameter with flat impacting surface whose edge radius is 1/2 inch or less. Cylinder is mounted on an unyielding base. 3. Thermal - 1475°F fire for 30 minutes with an emissivity coefficient of 0.9 and a package absorption coefficient of 0.8. Package shall not be cooled artificially for 3 hours.	1. The reduction of shielding would not be sufficient to increase the external radiation dose rate to more than 1,000 millirems per hour at 3 feet from the external surface of the package. 2. No radioactive material would be released from the package except for gases and contaminated coolant containing total radioactivity exceeding neither (i) 0.1 percent of the total radioactivity of the package contents; nor (ii) 0.01 curie of Group I radionuclides, 0.5 curie of Group II radionuclides, 10 curies of Group III radionuclides, 10 curies of Group IV radionuclides, and 1,000 curies of inert gases irrespective of transport group.

TABLE IV-1, CONDITIONS OF TRANSPORT (Continued)

C. Special Form

1. Drop Test - 30 foot drop onto a flat unyielding surface at critical angle.
2. Percussion - impact of a flat cylinder rod (1 inch diameter) weighing 3 pounds from a height of 40 inches onto the capsule which is supported by a lead sheet (Vickers #3.5 to 4.5) not more than one inch thick, supported by an unyielding surface.
3. Heating - 1475°F in air for 10 minutes.
4. Immersion - 24 hours in water at room temperature. PH6-PH8 water with a maximum conductivity of 10 micromhos/centimeter.

The capsule must retain its contents when subjected to all the performance tests prescribed in this section, and must not melt, sublime, or ignite at temperature below 1,475°F.

D. Shielding Standards

1. 200 mr/hr (maximum) at any point on surface of package.
2. 10 mr/hr at 3 feet from surface of the package.

E. Package Standards

1. The package lifting devices shall be capable of supporting 3 times the weight of the loaded package without exceeding the materials yield strength.
2. Failure at the lifting devices under heavy load shall not impair the containment or shielding properties of the package.
3. Tiedown devices - Without exceeding the yield strength of the package material, apply a static force to the center of gravity of the package with a vertical component equal to 2 times the weight of the package, a horizontal component along the direction the vehicle travels of 10 times the weight of the package and a horizontal component in the transverse direction of 5 times the weight of the package.
4. Load resistance - Simple beam supported at ends along any major axis, package shall be capable of withstanding a static load normal to and uniformly distributed along its length, equal to 5 times its fully loaded weight without exceeding the yield strength of the package.
5. External pressure - Containment vessel will suffer no loss of contents when subjected to an external pressure of 25 psig.

V. ENVIRONMENTAL RESPONSE

In the preceeding section, the environments were described according to (1) Normal test condition, (2) Hypothetical accident condition, (3) Special form material, (4) Shielding standards, and (5) Package standards. The purpose of this section is to show by analysis, test or relation to a more severe environment, that the fuel will be contained and radiation does not exceed 1000 millirem at 3 feet from the surface under all specified conditions.

The following describes the response of the generator to the environments in the sequence given in Table IV-1.

A. NORMAL TRANSPORT CONDITIONS

1. The environment on which this analysis was based (Item A.1) consisted of the generator on short circuit in direct sunlight at ambient temperature of 130°F in still air. Exposure of the generator to this environment results in a maximum temperature of 1493°F for the capsule structural member and 1279°F for the biological shield (see Appendix B). These temperatures will not cause any adverse effects on the safety aspects of the system.

2. The design of the generator and materials used eliminate any detrimental safety effects occurring by having the generator exposed to a -40°F temperature in still air and shade as described in Item A.2.

3. An atmospheric pressure 0.5 times the standard atmospheric pressure (Item A. 3) is far less severe than the case analyzed for the external pressure case given in Appendix A.

4. The vibration loads normally incident to transportation (Item A. 4) were not specified. In view of the far more severe requirements given in Table IV-1 and particularly the requirement given for the tiedown case, the vibration requirement was taken as a less severe condition.

5. The requirement given in Item A. 5 is of no concern since the generator was designed to sustain a seawater pressure at a depth of 2000 feet (See Appendix A).

6. A drop of four feet at the package critical angle on an unyielding surface as stated in Item A. 6 would not cause any damage which would effect the containment of the fuel or reduction in the biological shield (See Appendix A).

7. The energy available from a 13 pound cylinder dropping through a distance of 40 inches (520 inch-pounds) as described in Item A. 7 would at most cause a slight dent in the aluminum housing. The other impact cases are of a higher energy magnitude.

8. A compression load equal to five times the package weight applied to both the top and bottom of the package was found to be a less severe environment than the hydrostatic requirement (1300 psi) analyzed in Appendix A.

9. See section V-B for hypothetical accident cases.

B. HYPOTHETICAL ACCIDENT CONDITIONS

1. An analysis was conducted for the generator dropping 30 feet onto an unyielding surface at the generator's critical angle. The approach used was considered conservative in that no credit was taken for the impact capability of the generator aluminum housing. The results showed that the total energy capability of the insulation and shield (705,000 inch-pounds) is greater than that available from impact of the generator (620,000 inch-pounds) (see analysis in Appendix A). Additional analysis provided in Appendix C showed that stresses at impact on the shield lid attaching bolts are below their yield value. Therefore, failure of the heat shield will not occur nor will the biological shielding characteristics of the heat shield be impaired. R4

2. A 40 inch drop of the generator onto a 6 inch diameter cylinder would result in the load being spread over the thick walled aluminum housing. This case is of a much lower energy level than the previous case. Release of fuel or reduction in the radiation shield will not occur.

3. The 1475°F fire as described in Section IV will not cause fuel release or effect the radiation shielding characteristics of the heat shield. The analysis described in Appendix B was considered conservative in that the initial conditions were taken from the results obtained from the nominal test conditions (Item A. 1). The resulting maximum temperature prior to a 3 hour elapse time was approximately 1400°F for the shield and 1580°F for the capsule. This temperature will not effect the heat shield or capsule.

C. SPECIAL FORM MATERIAL

1. Impact of the fuel capsule from 30 feet results in an impact velocity of 43.5 fps. The critical impact velocity for the fuel capsule was calculated to be 248 fps. (See Appendix A). Failure of the fuel capsule will not occur.

2. The Puncture Case (hypothetical accident conditions) as discussed in case 2 above was found to be more severe.

3. The thermal environment analyzed above (1475 ^{o}F) was far more severe.

4. The SENTINEL 100F was designed to sustain seawater pressure at a depth of 2000 feet. A structural analysis was conducted (Appendix A) using an external pressure of 11300 psi. The results of this analysis showed that the generator would retain its integrity. The capsule was evaluated using an external pressure of 14,500 psi. The results given in Appendix A show the capsule will retain its integrity. Immersion in water for 24 hours is a far less severe condition.

D. SHIELDING STANDARDS

The tungsten biological shield was designed to meet the AEC radiation standards as given in Table IV-1. Analysis have shown that these standards will be satisfied.

E. PACKAGE STANDARDS

1. The package lifting device will be proof tested to 10,500 pounds as per Reference 7.

2. Failure of the lifting devices will not impair the containment or shielding properties of the package. Failure of the lifting devices would result in a far less severe environment than that described in Chapter IV. B. 1.

3. The structural analysis given in Appendix A showed that for the environment described in Item E. 3. the generator tiedowns would be capable of handling greater loads.

4. The loading described in Item E.4 was found to be far less severe than the 1300 psi external environment analyzed in Appendix A.

5. The generator and capsule were evaluated under far more severe external pressure environments.

VI. IAEA TRANSPORT REGULATIONS - SAFETY SERIES 6

The preceeding chapters covered the requirements for interstate transport of the SENTINEL 100F generator. This chapter is concerned with the additional requirements which must be satisfied in order to obtain the international transport permit.

Most of the requirements set forth in Safety Series No. 6 were covered by the interstate safety standards covered in Chapter IV. Minor variations required for shipment as general cargo are:

(1) In still air and direct sunlight at ambient temperature (38°C), the package surface temperature may not exceed 122°F.

(2) Radiation originating from the package shall not exceed 200 mr/hr on the surface and 10 mr/hr at a distance of one meter from the center of the package.

The first requirement is assured by the protective cage over the generator, but there is no generator safety problem in any case. The radiation level at one meter from the center is marginal, but should it exceed 10 mr, the generator can still be shipped by observing special handling requirements.

Safety Series 6, C-6.2.3, also lists specific requirements regarding the package design. These were reviewed and the following resolutions established.

(1) An analysis was conducted which showed that the generator would retain its integrity under all of the requirements of Annex IV, I-2, I-4 and C-2.3.1(a).

(2) No filters are used in the SENTINEL 100F design.

(3) No vents are provided or required in this design.

(4) Cooling is accomplished within the basic passive design. Even complete loss of cooling fins would not present a hazard.

(5) The fuel capsule does not require a pressure relief system. A seal weld assures positive containment.

(6) The containment vessel is designed to withstand much higher pressures.

(7) The generator and capsule were designed to take into account any build-up of internal pressure. Actually, external operating pressures will be more severe.

(8) Heat transfer is through metallic components in all cases.

(9) Not applicable to this design.

(10) Not applicable to this design.

(11) Not applicable to this design.

VII. CONCLUSIONS

This report describes all requirements pertinent to the interstate or international transport of the SENTINEL 100F. By means of analysis test or by comparison to a less severe requirement, all requirements have been satisfied. In view of the conservatism used in the analysis and past experience in transporting SENTINEL generators, there appears to be no reason why the SENTINEL 100F cannot be safely transported.

VIII. ADDITIONAL SUPPORT DATA

Although not specifically required for obtaining either the interstate or international licenses, some additional studies were conducted. As part of the design criteria, the generator housing was evaluated (Appendix A) in an external pressure environment of 1300 psi. The analytical results showed that the generator housing has the capability of sustaining this external pressure. The design criteria also specified that the fuel capsule would retain its integrity in a 14,500 psi external pressure envieonment. The results given in Appendix A verify the fuel capsule's capability to meet the criteria.

An analysis was conducted to evaluate the thermal shock capability of the fuel capsule (Appendix A). The capsule was taken as being at its operating temperature and then plunged into water at 0° C for a duration of 10 minutes. The results show that the fuel capsule will retain its integrity.

APPENDIX A

STRUCTURAL ANALYSES

I. INTRODUCTION

The following analyses present an evaluation of the SENTINEL 100F thermoelectric generator and/or fuel capsule. Based upon the requirements described in Chapter IV, the following conditions were analyzed.

A. GENERATOR

1. Free drop through a distance of four feet onto a flat unyielding surface.
2. Forty inch drop of a vertical steel cylinder 1-1/4 inches in diameter and weighing 13 pounds. Impact occurs on most vulnerable area of package.
3. Nine meter drop onto unyielding surface at critical angle.
4. Forty inch drop of generator onto a 6 inch diameter steel bar supported by an unyielding surface. The bar length is 8 inches with the edges of the flat end being rounded to a maximum radius of 1/4 inch.
5. Exposure of the generator housing to an external hydrostatic pressure of 1300 psi.
6. Without exceeding the yield strength of the package tie downs, apply a static force through the package center of gravity of two times the package weight vertically, 10 times the weight horizontally and five times the weight of the package in the transverse direction.

B. FUEL CAPSULE

1. Response to an external pressure of 10,000 psi to meet design requirements.
2. Response to an external pressure of 14,500 psi.

3. Response to an impact resulting from a nine meter drop onto a non-yielding surface.

4. Response of dropping a steel rod weighing seven kilograms from a height of one meter.

5. Thermal shock capability of the fuel capsule.

II. SUPPORT DATA

Figure A-1 provides a sketch of the generator cross-section and the pertinent dimensions and data used in the above analyses.

In support of these analyses, structural properties of the various components at temperature are required. The shield is fabricated from a tungsten alloy where the operational soak temperature is ~1130°F. Minimum values of strength and elongation at 1300°F given in Reference A-1 are as follows:

Ultimate Strength	30,000 psi
Compression Yield (@0.2%)	25,500 psi
Elongation	4%

In addition, the density is 0.61 lbs/in^3 and the elastic modulus at 1300°F is 38 x 10^6 psi.

With reference to Figure A-1, the upper ring and lower plate are employed to increase the volume of effective crushable thermal insulation under impact conditions. These components are fabricated from Inconel 700 or equivalent. The operating temperature is ~1100°F. At this temperature, the following structural properties are provided (Reference A-2).

FIGURE WITHHELD UNDER 10 CFR 2.390

FIGURE A1

SENTINEL 100 F

ıate Strength	145,000 psi
ı Strength	95,000 psi
tic Modulus	27×10^6 psi
gation	25%

ıaterials are utilized, Min-K 1301 and Glasrock Foam

ılus of Min-K 1301 is ~5400 psi and the stress-strain

ı and unrestrained Min-K are provided in Attachment 1.

the crushing capability of Glasrock is 1000 psi.

I. GENERATOR ANALYSES

impact analysis for the generator falling through a dis-

to a rigid surface, the structural capability is based

eld and the surrounding insulation. For conservatism,

ıbility of the aluminum housing is neglected.

e shield, capsule and fuel is ~1750 pounds.* Thus, for

gy becomes 1750 (9)(39.37) or 620,000 inch-pounds.

ed with this drop height is,

$$\sqrt{2gh}$$

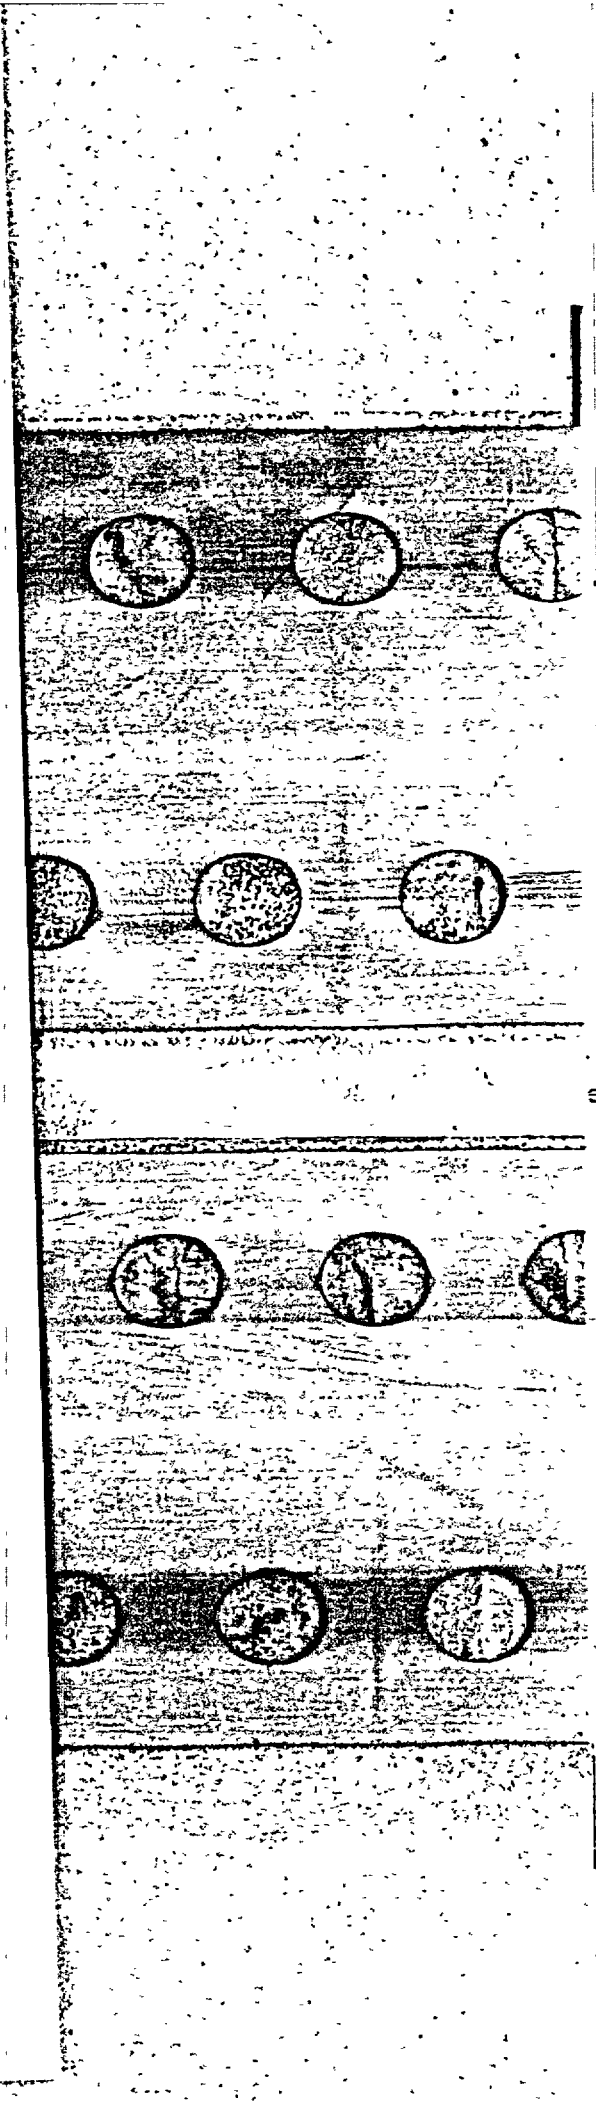
$$[2(386)(9)(39.37)]^{\frac{1}{2}} = 524 \text{ in/sec.}$$

· the shield may be derived from the wave equation,

$$\ddot{} = \frac{\partial \sigma}{\partial x}$$

-e displacement and σ is the stress magnitude.

*. Actual design weight is 1604 pounds. R4



Assuming a bilinear stress-strain curve for the material of interest, a critical impact velocity associated with stress wave propagation can be derived. This derivation is provided in Attachment 2. The critical velocity becomes,

$$V_{cr} = \frac{\sigma_y}{\sqrt{\rho E}} + \frac{\sigma_u - \sigma_y}{\sqrt{\rho F}}$$

where: E = elastic modulus

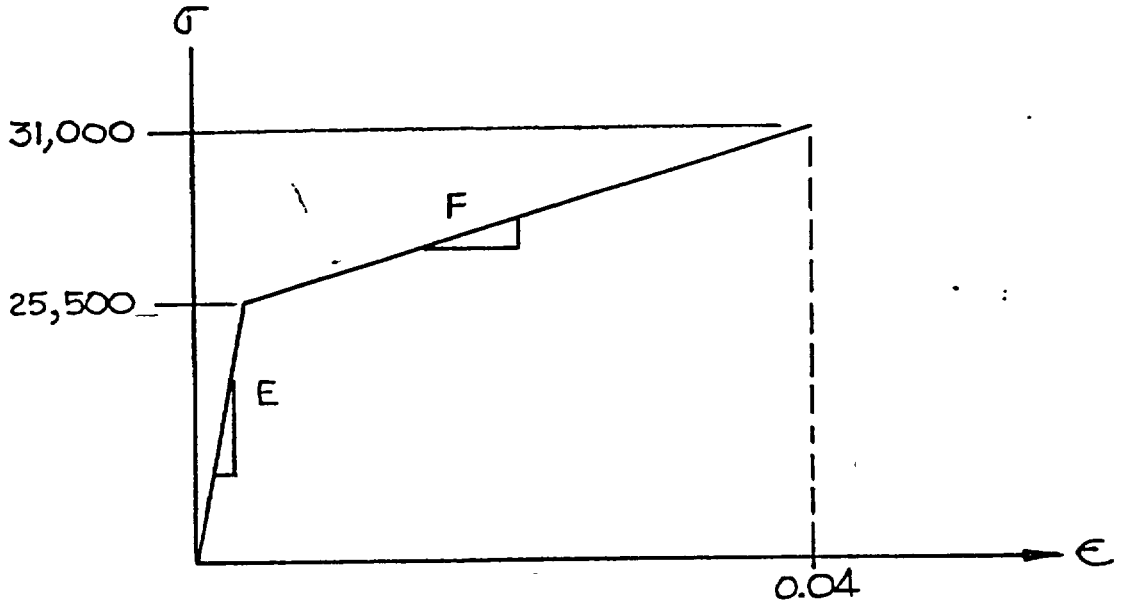
F = plastic modulus

ρ = mass density of material

σ_y = yield strength

σ_u = ultimate strength

For Kennestrium W-10 at temperature, the following stress-strain curve is obtained.



The plastic modulus or slope of the strain-hardening portion is derived from the curve geometry.

$$\therefore F = \frac{31000 - 25500}{.04 - \frac{25500}{38 \times 10^6}} = 14.0 \times 10^4 \text{ psi}$$

The elastic modulus and material density are 38×10^6 psi and 0.61 lb/in^3, respectively. Substituting into the equation for critical velocity,

$$V'_{cr} = \frac{25500}{\sqrt{\left(\frac{.61}{386}\right)\left(38 \times 10^6\right)}} + \frac{31000 - 25500}{\sqrt{\left(\frac{.61}{386}\right)\left(14 \times 10^4\right)}}$$

$$= 474 \text{ in/sec.}$$

The equivalent energy is,

$$E = 1/2\ mV^2 = \frac{1750}{2(386)} (474)^2 = 5.09 \times 10^5 \text{ in-lbs.}$$

A substantial amount of available energy is absorbed by the compressibility of the insulation. For the impact of the generator in the upright orientation, the lower plate of 16.38 inch OD becomes an effective load path to an equivalent area of insulation. The plate is effective to the limit of its structural capability where abnormal deflection would take place. The loading would be nearly a uniform pressure load reacted by an annular simple support at 8.84 inch shield diameter (See Figure A-2).

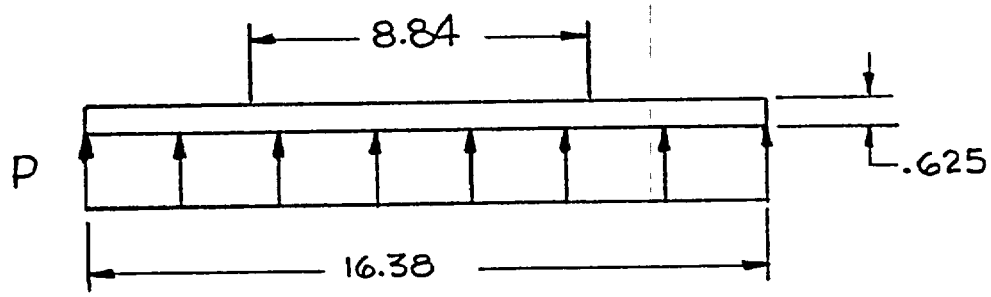


FIGURE A-2 ANNULAR SIMPLE SUPPORT

From Reference A-4, the radial and tangential bending moments are given by,

At r = o:

$$M_r = M_t = \frac{pa^2}{16}(3+\nu) - \frac{W}{4\pi}(1+\nu)\left[\frac{1}{2}\left(\frac{1-\nu}{1+\nu}\right)\left(1-\frac{b^2}{a^2}\right) + \text{In}\ \frac{a}{b}\right]$$

At $a \geq r \geq b$:

$$M_r = \frac{pa^2}{16}(3+\nu)\left(1-\frac{r^2}{a^2}\right) - \frac{W}{4\pi}(1+\nu)\left[\frac{1}{2}\left(\frac{1-\nu}{1+\nu}\right)\left(\frac{b^2}{r^2}-\frac{b^2}{a^2}\right)+\text{In}\ \frac{a}{r}\right]$$

$$M_t = \frac{pa^2}{16}(3+\nu)\left[1-\left(\frac{1+3\nu}{3+\nu}\right)\frac{r^2}{a^2}\right] - \frac{W}{4\pi}(1+\nu)\left[\frac{1}{2}\left(\frac{1-\nu}{1+\nu}\right)\left(2-\frac{b^2}{r^2}-\frac{b^2}{a^2}\right)+\text{In}\ \frac{a}{r}\right]$$

where: $W = \pi pa^2$

a = outer radius = 8.19"

b = support radius = 4.42"

The maximum bending moment occurs in the radial direction at r = 4.42. In a unit pressure and $\nu = 0.3$ the maximum moment becomes,

$$M_{max} = 7.808 \text{ in-lbs./inch.}$$

The stress-moment relationship is,

$$\sigma = \frac{6M}{t^2}$$

With a bending factor of 1.5, a yield stress at temperature of 95,000 psi for Inconel 700 and a plate thickness of 0.625 inches, the equivalent pressure loading is,

$$p = \frac{1.5\,(\sigma_y)t^2}{6(7.808)} = \frac{1.5\,(95000)(.625)^2}{6(7.808)}$$

$$= 1188 \text{ psi.}$$

This represents a conservative loading since in a bending mode the plate rigidity and capability is above yielding.

The majority of available energy would be taken up by the Min-K insulation rather than the Glasrock. The total volume of insulation under the plate is,

$$v = \pi(4)(8.19)^2 = 841 \text{ cu. in.}$$

The strain energy capability per unit volume of the insulation is represented by the area under the stress-strain curve. With a limit load of 1188 psi, the area under the stress-strain curve is obtained from Figure 1A of Attachment 1. The area is ~233 in-lbs./in^3. For 841 cubic inches, the total available energy is,

$$E = 841 \text{ in}^3 \ (233 \text{ in-lbs/in}^3)$$

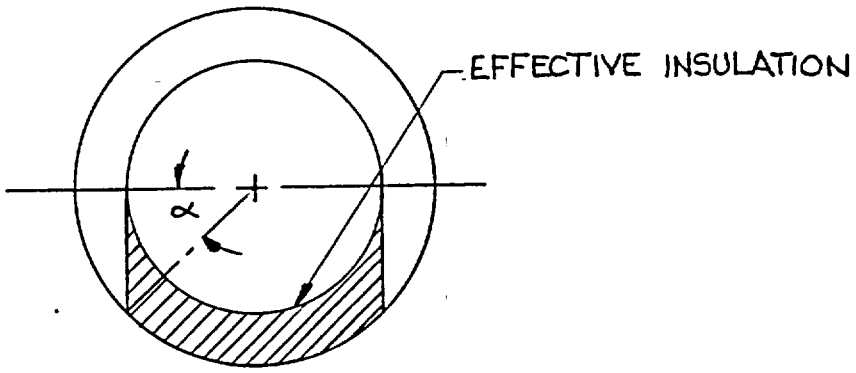
$$= 196,000 \text{ in-lbs.}$$

The total energy capability of the insulation and shield for the vertical drop is 196,000 and 509,000 in-lbs., respectively, for a total of 705,000 in-lbs. This value is greater than the 620,000 in-lbs. of available energy associated with the nine meter drop. In other words, the shield will decelerate through the insulation and the impact velocity of the shield will not exceed the 474 in/sec limit.

A far more conservative approach is to apply only the Min-K insulation where the volume is 450 in^3; 450(233) equals 105,000 inch-pounds. This value coupled with the 509,000 inch-pounds associated with the shielding yields a total of 614,000 inch-pounds. Certainly the large volume of Glasrock will absorb much more than the 6000 inch-pounds remaining.

Secondly, the 233 inch-pounds per cubic inch of Min-K is conservative. In reality, the shield enclosed within the insulation would never see a "hard" impact (high g-level).

When considering impact on the side of the generator, it can be shown that the effective volume of insulation is considerably higher than for any other impact orientation.



For every inch of shield length, the effective crushable insulation volume is,

$$v_I = \frac{1}{2}\left[\frac{\pi}{4} D_o^2 - \frac{\pi}{4} D_1^2 - \left(\frac{D_o}{2}\right)^2 (2\alpha - \sin 2\alpha)\right]$$

$$= \frac{1}{2}\left[\frac{\pi (20.63)^2}{4} - \frac{\pi (13.84)^2}{4} - (10.315)^2 (1.676 - .994)\right]$$

$$= 55.7 \text{ in}^3$$

Hence, for a shield of ~19.7 inches in length, the total effective insulation is 1097 cubic inches.

For an impact where the generator is inverted, the upper ring (17.5"OD, 13.03" ID) is applied as a load path to crushable insulation. Its limit load in bending is derived from the equation,

$$\sigma_{max} = K\rho \frac{a^2}{t^2}$$ (Reference A-5)

Where 'a' is the outer radius of the plate and t is the plate thickness. For $a/b = (\frac{17.5}{2})(\frac{2}{13.03}) = 1.34$, $k \cong 0.90$. Applying a similar analysis as performed for the lower plate, the limit load becomes,

$$P = \frac{1.5\,\sigma_y\,t^2}{k\,a^2} = \frac{1.5\,(95000)(.75)^2}{.90\,(8.75)^2}$$

$$= 1164 \text{ psi.}$$

The volume of effective insulation is,

$$v = 3.88(\tfrac{\pi}{4})\left[(17.5)^2 - (13.03)^2\right] + \frac{\pi}{4}(13.5)^2(0.6) = 501 \text{ in.}^3$$

The strain energy associated with this loading and volume of Min-K 1301 is,

$$E \cong 501\,(233) = 116,700 \text{ in-lbs.}$$

Similarly,

$$509,000 + 116,700 = 625,700 \text{ in-lbs.} > 620,000 \text{ in-lbs available.}$$

The above comparison between strain energy capability and available energy from a nine meter drop is not marginal. The energy absorbed by the compression of the module springs and the energy absorbed by the housing were conservatively omitted from the analysis. The latter is certainly significant.

The other impact conditions defined in the beginning of this report are not significant. A free drop through a distance of four feet to a rigid surface defines an energy level below that previously evaluated. The condition of a 40 inch free drop onto a six inch diameter bar pertains to a lower available energy. The diameter of the bar is of a magnitude where local bending would take place as opposed to penetration. The shield will not see any local loading effect. The thick walled housing will effectively spread the load such that only energy levels need be compared.

A similar argument may be used for the percussion condition where a 13 pound steel cylinder goes through a drop height of 40 inches. Hence, we have only 13(40) or 520 inch-pounds; a negligible energy that should provide no more damage than causing a slight dent in the housing surface.

IV. HOUSING ANALYSES

The following delineates a structural evaluation of the SENTINEL 100F RTG housing under conditions of external hydrostatic pressure. A sketch of the housing is provided in Figure A-3 per INSD Drawings 010-40000 and 010-70000. The external proof pressure is 1300 psi where the housing lid deflection is limited to .020 inches.

The generator housing (23.88" OD and 20.62" ID) is fabricated from 6061-T6 aluminum alloy with the following minimum structural properties per Reference A-6 for parent material and weld test data:

Parent Material	Weld Material
F_{tu} = 42000 psi	F_{tu} = 25000 psi
F_{ty} = 35000 psi	F_a = 16600 psi
$E = 9.9 \times 10^6$ psi.	

The maximum stress in the cylindrical shell occurs at the inner surface in the circumferential direction. This stress is given by,

$$\sigma_{\theta m} = \frac{2pb^2}{b^2 - a^2}$$

For an external pressure of 1300 psi (the proof pressure),

$$\sigma_{\theta m} = \frac{2(-1300)(11.94)^2}{(11.94)^2 - (10.31)^2} = -10,200$$

This value is well below the 35000 psi yield strength.

FIGURE WITHHELD UNDER 10 CFR 2.390

FIGURE A3

SENTINEL 100F HOUSING

FIGURE WITHHELD UNDER 10 CFR 2.390

FIGURE A3

SENTINEL 100F HOUSING

Solving for Q_o and M_o,

$$Q_o = 3.784 \text{ lbs/in.}$$

$$M_o = -8.523 \text{ in-lbs/in.}$$

The combined stresses are given by the following expressions:

$$\sigma_x = \frac{-a^2}{b^2 - a^2} \pm \frac{6}{t_c^2} \left[M_o \phi + \frac{1}{\beta} Q_o \Omega \right]$$

where upper sign indicates inside surface and lower sign the outside surface.

$$\sigma_\theta \text{ (inside)} = \frac{-2b^2}{b^2-a^2} + \left[2\beta^2 \frac{R}{t_c} \psi + \frac{6\nu}{t_c^2} \phi \right] M_o + \left[\frac{2\beta R}{t_c} \theta + \frac{6\nu}{\beta t_c^2} \Omega \right] Q_o$$

$$\sigma_\theta \text{ (outside)} = \frac{-(a^2 + b^2)}{b^2-a^2} + \left[2\beta^2 \frac{R}{t_c} \psi - \frac{6\nu}{t_c^2} \phi \right] M_o + \left[\frac{2\beta R}{t_c} \theta - \frac{6\nu}{\beta t_c^2} \Omega \right] Q_o$$

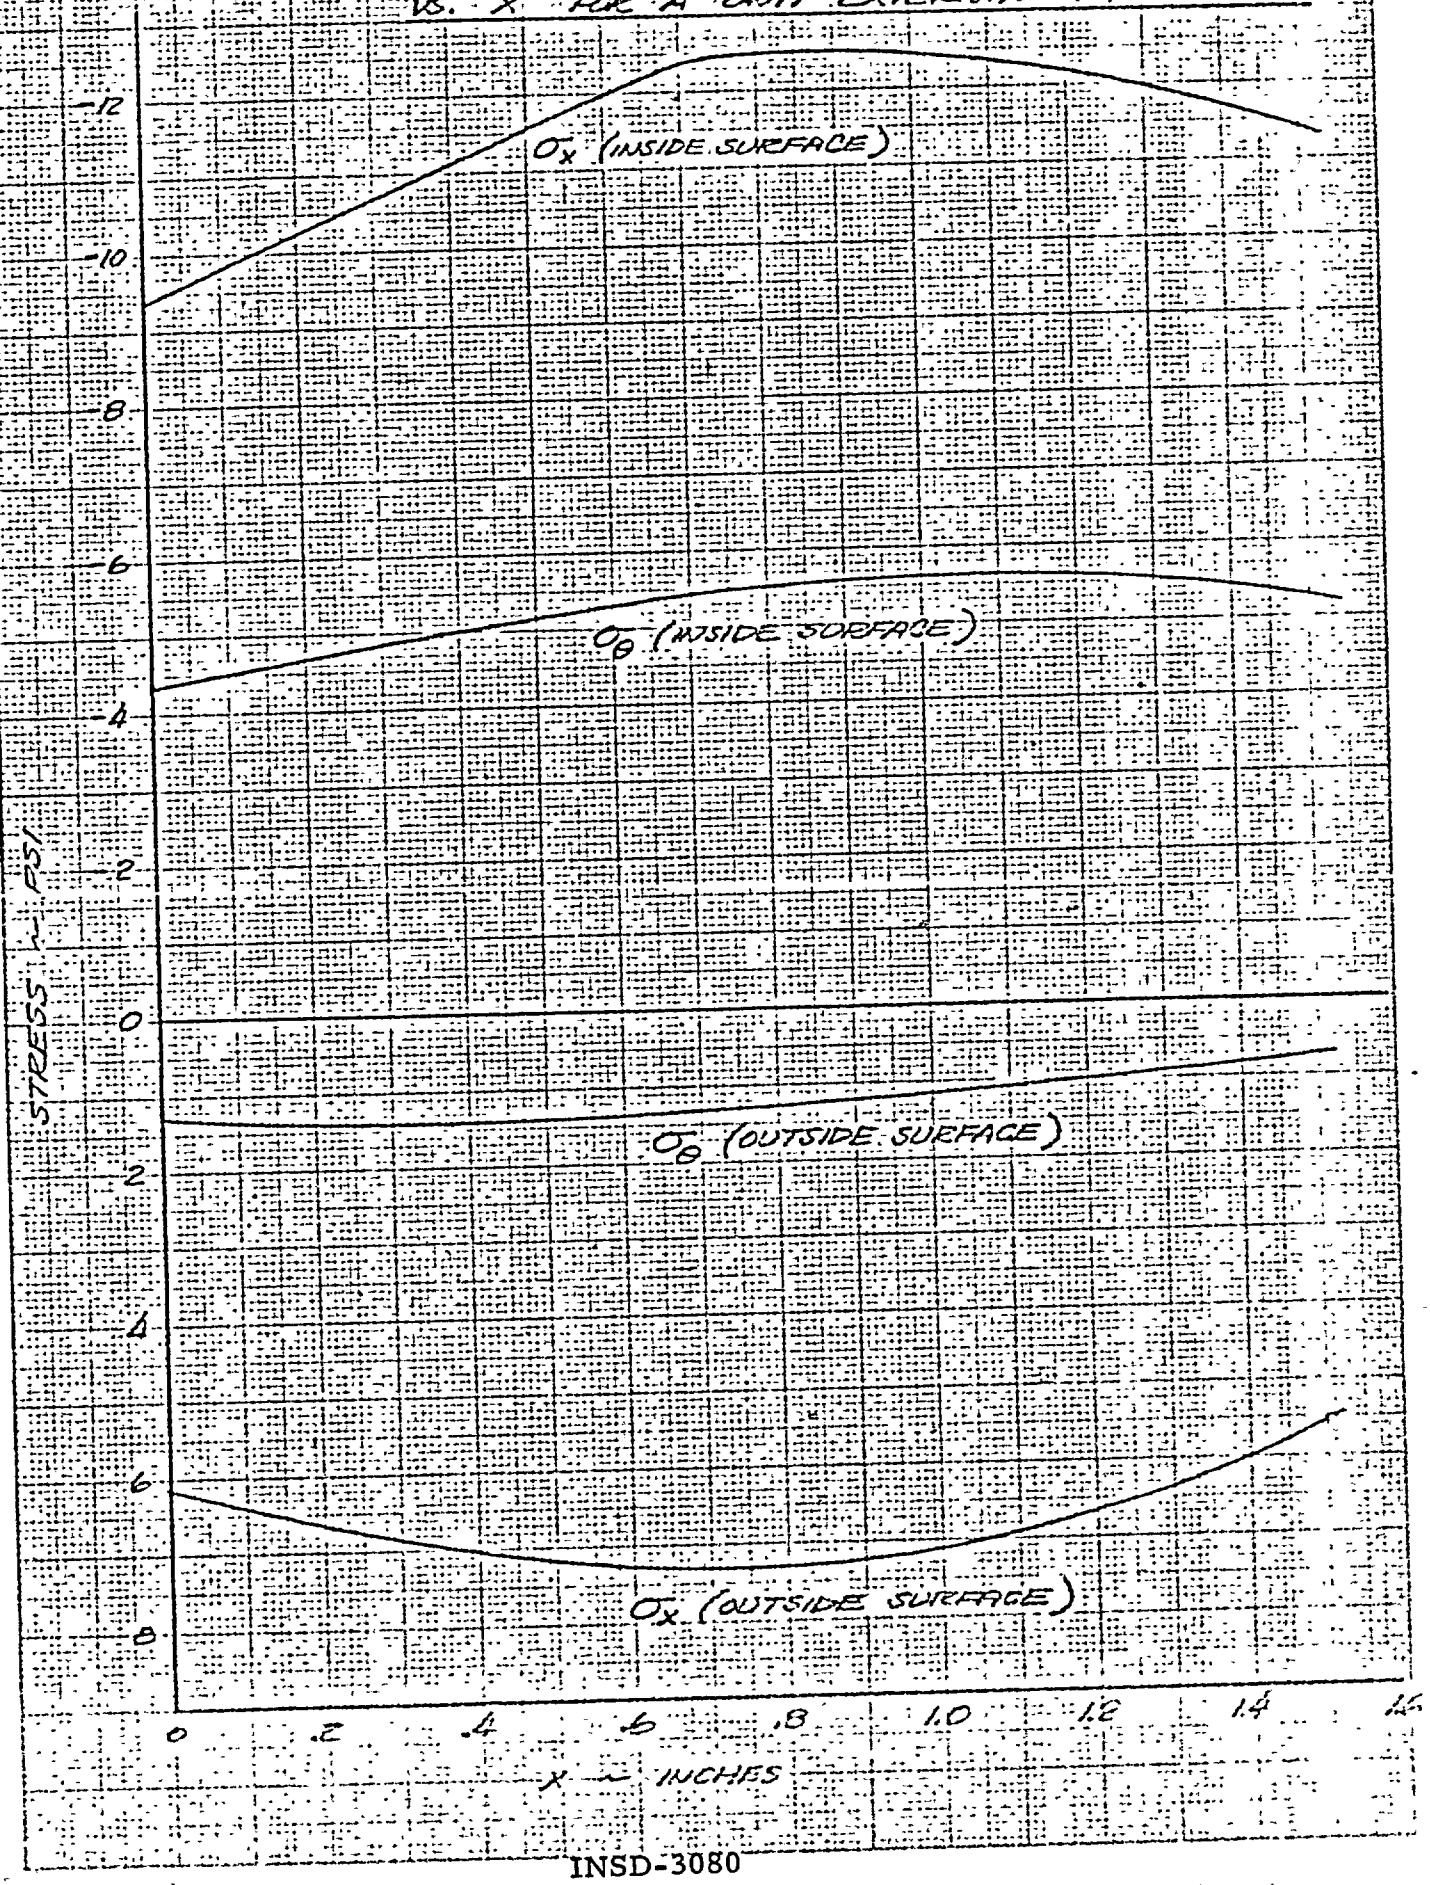
where $\beta = \frac{3(1 - \nu^2)^{\frac{1}{4}}}{R^2 t_c^2} = 0.302$

θ, Ω, ψ and ϕ are functions of x (per Figure A-4) and the attenuation length $1/\beta$. These functions are found in graphical form in Reference A-7. Substituting into the above equations, the combined stresses on both surfaces and in both directions can be obtained for the unit external pressure. The results as a function of x are shown in Figure A-5.

The maximum stress per Figure A-5 is ~ 12.5 psi per unit pressure. This occurs in the axial direction at the inside surface. For the proof pressure of 1300 psi, the resulting peak stress is 1300 (12.5) or 16250 psi which is below the allowable stress in the weld material.

FIGURE A-5

COMBINED MEMBRANE & DISCONTINUITY STRESSES VS. X FOR A UNIT EXTERNAL PRESSURE



The closure head is essentially a clamped circular plate where its edge fixity is dependent upon the moment M_o. From Reference A-8, the stress at the center of the plate becomes,

$$\sigma_r = \frac{3W}{8\pi mt^2}(3m + 1) - \frac{6M_o}{t^2}$$

where $W = \pi pR^2$ and $m = \frac{1}{\nu}$. In this instance the effective plate radius is 11.125 inches. Therefore,

$$\sigma_r = \frac{3(\pi)(1300)(11.125)^2(11)}{8\pi(3.33)(3.25)^2} - \frac{6(1300)(8.53)}{(3.25)^2}$$

$$= 18850 - 6300 = 12,550 \text{ psi.}$$

At the edge (with increased thickness), the radial stress is simply $6\ M_o/t^2$ where t = 3.5 inches.

$$\therefore \sigma_r = \frac{6(8.53)(1300)}{(3.5)^2} = 5430 \text{ psi}$$

The housing lid is also fabricated from 6061-T6 aluminum alloy with an effective diameter and thickness of 20.38 and 4.517 inches respectively. The lid is held to the housing shell by eighteen 5/8" diameter aluminum bolts on a 25.625 inch bolt circle. As was previously stated, the design of the lid or cover is based upon a maximum permissible deflection of .020 inches from an external proof pressure of 1300 psi.

From the eighteen lid bolts, the boundary condition for the circular lid is between clamped and simply supported. The bolts are relatively wide spaced such that the fixity tends toward the latter condition. Secondly, it is conservative to obtain the center deflection on the simply supported assumption. The maximum deflection for a simply supported circular

plate is given by the equation (Reference 3),

$$y_{max} = \frac{3W(M-1)(5m+1)R^2}{16\pi E m^2 t^3}$$

Therefore, for 1300 psi,

$$y_{max} = \frac{3(1300)(\pi)(10.31)^2(2.33)(17.67)(10.31)^2}{16\pi(9.9 \times 10^6)(3.33)^2(4.517)^3}$$

$$= .0112 \text{ inches} < .020 \text{ inches}$$

The stresses in the plate in the radial and tangential directions are also conservative with the simple support assumption. The maximum stress which would occur at the center of the plate is,

$$\sigma_{max} = \frac{3W(3m+1)}{8\pi mt^2}$$

$$= \frac{3(1300)(\pi)(10.31)^2(11)}{8\pi(3.33)(4.517)^2} = 8400 \text{ psi.}$$

This magnitude is also well below the yeild capability of 35,000 psi.

The stress in the bolts is limited to the potential deflection of the lid at the bolt circle. If the lid was simply supported, the slope of the lid at the 10.31 inch radius would be,

$$\theta = \frac{3W(m-1)R}{2\pi E mt^3}$$

$$= \frac{3(1300)(\pi)(10.31)^2(2.33)(10.31)}{2\pi(9.9 \times 10^6)(3.33)(4.517)^3} = .00164 \text{ radians.}$$

Since the angle is small, $\theta \cong \sin\theta \cong \tan\theta$. The distance between the shell ID and the bolt circle is 12.813 - 10.310 or 2.503 inches. Thus, the maximum possible bolt elongation is,

$$\delta = 2.503\ (.00164) = .00411 \text{ inch.}$$

The effective bolt length is ~ 6.12 inches and hence the strain becomes,

$$\epsilon = \frac{.00411}{6.12} = .000672 \text{ in/in.}$$

The bolts are 2024-T4 aluminum having an elastic modulus of 10.5×10^6 psi. Therefore,

$$\sigma = E\epsilon = 10.5 \times 10^6\ (.000672)$$

$$= 7050 \text{ psi.}$$

The yield strength of 2024-T4 is 42000 psi (minimum).

V. STRUCTURAL ANALYSIS - TIE DOWN FITTINGS

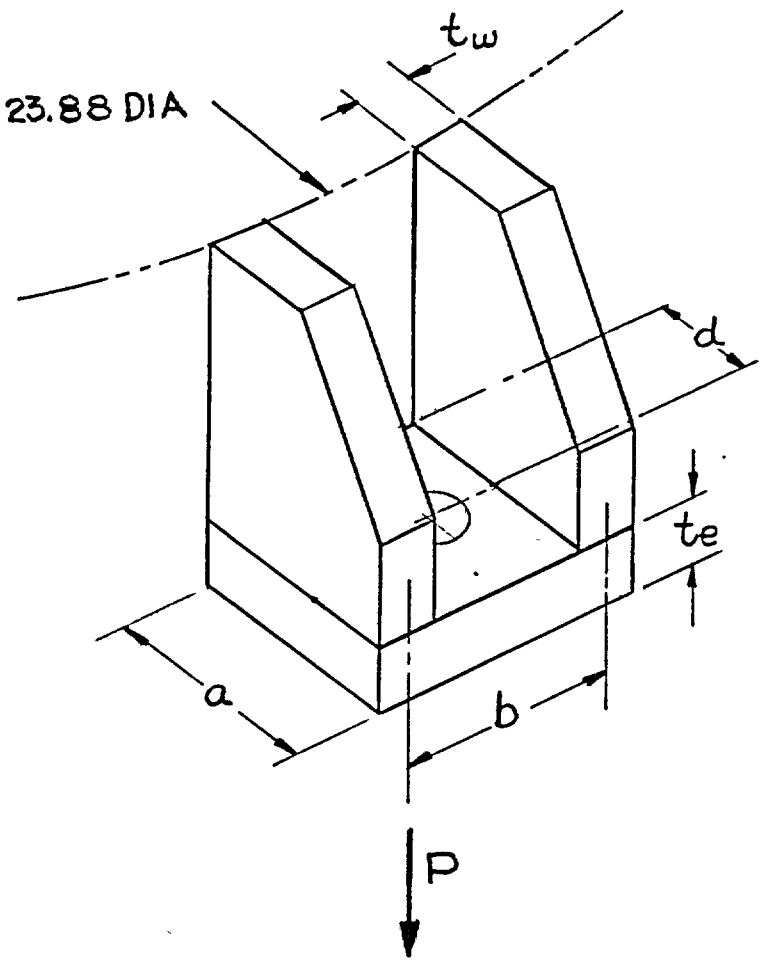
Four channel fittings as illustrated in Figure A-6 provide a tie down capability to the generator pallet. The fittings of 6061-T6 aluminum alloy are welded to the base periphery of the housing with a generous weld bead at all interface surfaces such that the critical area is in the parent material.

An analysis of end pad bending is based upon the approach given in Reference A-9 for tension type fittings.

$$\frac{r_i}{a} = \frac{.531}{3.25} = .1635$$

$$\frac{b}{a} = \frac{4.75}{3.25} = 1.462$$

$$\rightarrow K \cong 0.76$$



r_i = hole radius = .531"
te = 1.0" minimum
b = 4.75"
t_w = .75"
d = 1.747"
$a \approx 3.25$"

FIGURE A6

CHANNEL FITTING

The bending stress is,

$$\sigma_b = \frac{2P\,d\,K}{a t_e^2}$$

where P is the applied load.

Neglecting the bending form factor the load to yield the material is derived where the yield strength is 35,000 psi minimum.

$$\therefore P_y = \frac{\sigma_y\, a\, t_e^2}{2\,d\,K}$$

$$= \frac{35000(3.25)(1.0)^2}{2(1.747)(0.76)} = 42,800 \text{ pounds.}$$

The ultimate shear stress for 6061 heat treated to the T6 condition is 27000 psi (Reference 6). Assuming that an approximate shear yield can be derived from the ratio between ultimate and yield in tension,

$$\tau_y \cong 27000 \left(\frac{35000}{42000}\right) = 22,500 \text{ psi}$$

The minimum shear area is,

$$A_s = 2(3.25)(.75) + 5.5\,(1) = 10.375 \text{ in}^2$$

The associated load becomes,

$$P = 22500\,(10.375) = 233,000 \text{ pounds.}$$

The weight of the SENTINEL 100F generator is approximately 2600 pounds. Conservatively taking 42,800 pounds as a design limit load for each lug, this is equivalent to the following g-loading in the vertical direction:

$$G = \frac{4(42,800)}{2600} \cong 66 \text{ g's}$$

The shipping and handling conditions are next examined where the design g-loads are:

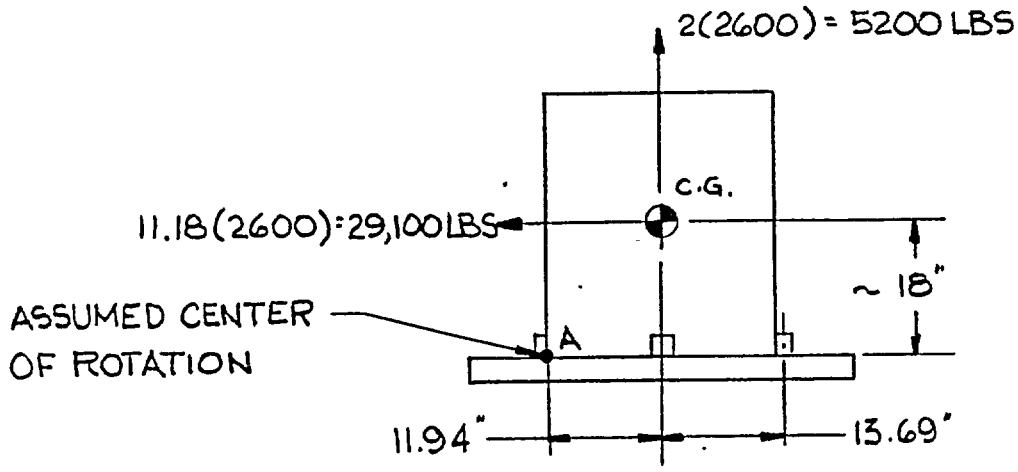
2 g's = vertical

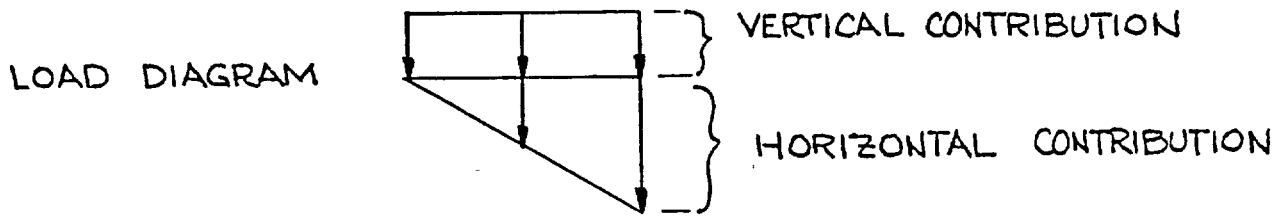
5 g's - lateral

10 g's - fore and aft.

The C. G. of the generator is approximately 18 inches above the pallet. Combining the lateral and longitudinal g-loads, the maximum g-load vector in the horizontal plane becomes,

$$G_H = \sqrt{(5)^2 + (10)^2} = 11.18 \text{ g's}$$





Taking summation of moments about point A for the horizontal load contribution, the maximum lug load is derived.

$$18(29100) = P_1 (13.69 + 11.94) + P_1 (11.94)$$

$$\therefore P_1 \doteq 13,930 \text{ pounds.}$$

The contribution from the vertical force is,

$$P_2 = \frac{5200}{4} = 1300 \text{ pounds.}$$

Superimposing, the maximum lug load becomes,

$$P_{max} = P_1 + P_2 = 13930 + 1300$$

$$= 15,200 \text{ pounds.}$$

This loading is far below the 42,800 pound limit load. Additional loadings can be evaluated as a function of generator-pallet orientation. However, the ratio of lug capability to lug load is very high and further examination is not justified.

VI. FUEL CAPSULE ANALYSES

A. EXTERNAL HYDROSTATIC PRESSURE OF 10,000 PSI

For an external hydrostatic design pressure of 10,000 psi, the calculated stresses must meet the following criteria:

$$\sigma \text{ (primary membrane)} \leq 0.9 F_{ty}$$

$$\sigma \text{ (load primary membrane)} \leq 1.35 F_{ty}$$

$$\sigma \text{ (secondary membrane)} \leq 2.7 F_{ty}$$

$$\sigma \text{ (buckling)} \leq 0.5 \sigma_{cr}$$

From Reference 10, the following room temperature structural properties are given for solution heat treated Hastelloy C. All values are guaranteed minimums.

Tensile strength, F_{tu} = 100,000 psi

Yield strength, F_{ty} = 46,000 psi

Elongation, ℓ = 20% in two inches

Elastic modulus, E = 28.5×10^6 psi

The wall thickness and inside radius of the capsule are 0.668 and 2.1125 inches, respectively. Assuming the Mises criterion for ductile materials, the maximum circumferential stress, occurring at the inner surface is given by the equation:

$$\sigma_\theta = \frac{1.732\, p r_o^2}{r_o^2 - r_i^2}$$ Reference A-8

where $r_o = r_i + t$

substituting,

$$\sigma_\theta = \frac{1.732(10,000)(2.790)^2}{(2.790)^2 - (2.1225)^2} = 41,115 \text{ psi}$$ R_1

$$\underline{\text{M.S.}} = \frac{0.9(46,000)}{41115} - 1 = .007$$ R_1

In order to investigate buckling capability, the critical buckling stress per Reference 11 is utilized where the effective cylindrical shell length is ~10.0 inches and R is the mean radius.

$$\frac{L^2}{Rt} = \frac{(10)^2}{2.4565\,(.668)} = 60.94$$ R_1

∴ Cylinder is of short or transition length.

For hydrostatic pressure, the critical buckling stress is:

$$\sigma_{cr} = \frac{K \pi^2 E t^2}{12(1 - \nu^2)L^2}$$ R_1

where K is a constant: $K = f(L, R, t)$; $\nu = 0.3$

$$Z_L = \frac{L^2}{Rt}(1 - \nu^2)^{\frac{1}{2}} = 60.94\,(.955) = 58.2$$ R_1

∴ $K \cong 8$

∴ $\sigma_{cr} = \frac{8(\pi)^2(28.5 \times 10^6)(.668)^2}{12(.91)(10)^2} = 0.917 \times 10^6$ psi

Rather than iterate with a tangent or reduced modulus to obtain an exact solution based upon stress-modulus compatibility, it is evident that the capsule would yield long before it would fail from instability.

Discontinuity stresses at the closure head-cylinder interface are next examined. As a result of a pressure loading on the capsule and a requirement for strain compatibility at the head-cylinder junction, a discontinuity moment M_o and shear Q_o must be superimposed with the general membrane solution. From Reference A-7,

$$M_o = -\frac{R^2 p}{8\lambda_c}\left\{\frac{2C^3\lambda_c^3 + 0.7C^4\lambda_c^2 + 4.42}{2C^3\lambda_c^2 + [.7C^4 + 1.3]\lambda_c + .91C}\right\}$$

$$Q_o = \frac{Rp}{4}\left\{\frac{C^3\lambda_c^3 + 3.4C^3\lambda_c + 4.42}{2C^3\lambda_c^2 + [.7C^4 + 1.3]\lambda_c + .91C}\right\}$$

where R= mean radius = 2.4565 inches | R_1

$$C = \frac{t_c}{t_h} = \frac{.668}{1.0} = .668$$

$$\lambda_c = \left[\frac{3(1-\nu^2)R^2}{t_c^2}\right]^{\frac{1}{4}} = 2.465 \quad | R_1$$

Solving for the discontinuity forces,

$M_o = -5585$ | R_1

$Q_o = 9000$ | R_1

The resulting stresses at the interface for the longitudinal and circumferential directions are,

$$\sigma_x = \pm \frac{6M_o}{t_c^2} - \frac{pR}{2t_c} = \begin{cases} -93487 \text{ psi} \\ +56713 \text{ psi} \end{cases} \quad | R_1$$

Margin of Safety (M. S.) = $\frac{2.7(46,000)}{93487} - 1 = 0.328$ | R_1

$$\sigma_\theta = \left[\frac{2\beta^2 R}{t_c} \pm \frac{1.8}{t_c^2}\right] M_o + \frac{2\beta R Q_o}{t_c} - \frac{pR}{t_c}$$

where $\beta = \left[\frac{3(1-\nu^2)}{R^2 t_c^2}\right]^{\frac{1}{4}} = 1.0138$ | R_1

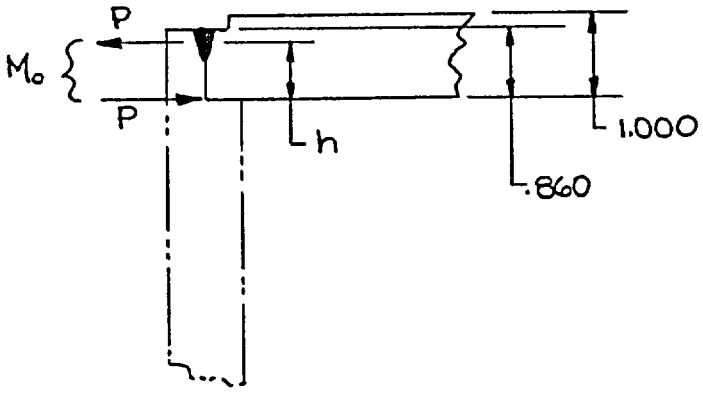
$$\therefore \sigma_\theta = \left[\frac{2(1.0138)^2(2.4565)}{.668} \pm \frac{1.8}{(.668)^2}\right](-5585) \quad | R_1$$

$$+ \frac{2(1.0138)(2.4565)(9000)}{.668} - \frac{10,000(2.4565)}{.668} \quad | R_1$$

$$= \begin{cases} -34,415 \text{ psi} \\ +10,644 \text{ psi} \end{cases} \quad | R_1$$

$$\text{M. S.} = \frac{1.35(46,000)}{34,415} - 1 = 0.804 \quad | R_1$$

An investigation of the fusion weld for the capsule lid makes use of the discontinuity moment M_o as shown below where the weld is in tension.



$M_o = hP = 5585$ in-lbs/in. | R_1

weld length (min.) = .180 in.

$h = .860 - \frac{.180}{2} = .770$ in.

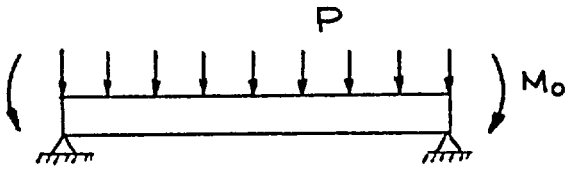
$$\therefore P = \frac{5585}{.770} = 7253 \text{ lbs/in.} \quad | R_1$$

The stress becomes,

$$\sigma = \frac{P}{A} = \frac{7253}{.180} = 40,294 \text{ psi} \quad \left| R_1 \right.$$

$$\text{M. S.} = \frac{.90(46,000)}{40,294} - 1 = 0.027 \quad \left| R_1 \right.$$

The lower closure is loaded as shown below



t = 1.0 in.

The bending stress at the edge is,

$$\sigma_b/\text{edge} = \frac{6\,M_o}{t^2} = \frac{6(5585)}{(1)^2} = 33,510 \text{ psi} \quad \left| R_1 \right.$$

At the center per Reference A-7.

$$\sigma_b/\text{center} = \frac{3W}{8\,\pi\,mt^2}\,(3m + 1) - \frac{6\,M_o}{t^2}$$

where: $W = \rho\,\pi R^2$

$$= 10,000\,\pi\,(2.4565)^2 = 189,576 \text{ pounds} \quad \left| R_1 \right.$$

$$m = \frac{1}{\nu} = \frac{1}{0.3} = 3.333$$

$$\sigma_b/\text{center} = \frac{3(189,576)(10)}{8\,\pi\,(3.333)(1)^2} - 33,300 = 34,594 \text{ psi} \quad \left| R_1 \right.$$

$$\text{M. S.} = \frac{1.35(46,000)}{34,594} - 1 = 0.795 \quad \left| R_1 \right.$$

A similar state of stress occurs at the upper closure or lid. The bending stress in the center is 34,594 psi and the stress across the weld was found to be 40,294 psi. $\left| R_1 \right.$

B. EXTERNAL HYDROSTATIC PRESSURE OF 14,500 PSI

An elastic-plastic analysis was performed for a similar capsule per Reference A-12 where the pressure was derived to initiate a plastic "front" on the inside surface in the circumferential direction.

$$\rho^* = \frac{\sigma_o}{2}\left(1 - \frac{r_i^2}{r_o^2}\right)$$

An estimate of the wall capability is obtained by letting σ_o equal the ultimate strength of 100,000 psi. Thus, the failure pressure becomes,

$$\rho_{ult.} = \frac{100,000}{2}\left[1 - \frac{(2.1225)^2}{(2.790)^2}\right] = 21,063 \text{ psi} \quad \left|R_1\right.$$

This value is significantly higher than the requirement of 14,500 psi and is conservative for at least two reasons.

(1) The 100,000 psi ultimate strength is a minimum guaranteed value. Actual material strength should be somewhat higher.

(2) The capsule is allowed to deform until it contacts the fuel, hence achieving an elastic foundation restricting elongation.

The maximum stress in the system occurs at the closure-cylinder interface in the axial direction due to membrane and discontinuity loads.

This stress becomes,

$$\sigma = \frac{14,500}{10,000}(93487) = 135,556 \text{ psi} \quad \left|R_1\right.$$

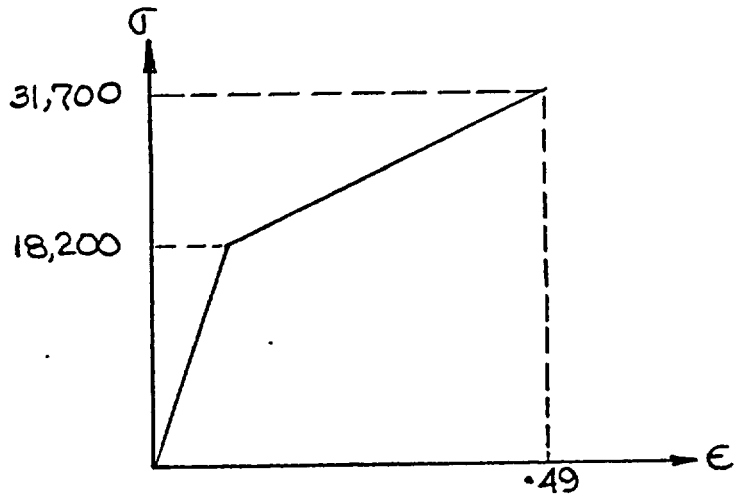
Applying a 1.5 bending form factor, the ultimate capability is 1.5(100,000) = 150,000 psi (minimum).

C. CAPSULE IMPACT

The fuel capsule must survive an impact consisting of a nine meter drop onto a hard surface. The shock resistance shall be determined on the basis of a critical impact velocity as a function of stress wave propagation. The environment of the capsule is conservatively assumed at ~1800°F. The critical impact velocity from Attachment 2 is,

$$\sigma_{cr} = \frac{\sigma_y}{\sqrt{\rho E}} + \frac{\sigma_u - \sigma_y}{\sqrt{\rho F}}$$

where E is the elastic modulus and F is the plastic modulus. The idealized linear strain hardening stress-strain curve for Hastelloy C at 1800°F is shown below (Reference A-13).



At 1800°F, $E = 15 \times 10^6$. The plastic modulus, F, is obtained by stress-strain curve geometry.

$$F = \frac{31700 - 18200}{.49 - \frac{18200}{15 \times 10^6}} = 27630 \text{ psi}$$

The mass density ρ is,

$$\rho = .323 \left(\frac{1}{386}\right) = 0.837 \times 10^{-3} \text{ lb-sec}^2/\text{in}^4$$

Solving for the critical impact velocity,

$$V_{cr} = \frac{18200}{\sqrt{(.837 \times 10^{-3})(15 \times 10^6)}} + \frac{135}{\sqrt{(.837 \times 10^{-3})(27630)}}$$

$$= 2975 \text{ in/sec} = 248 \text{ ft/sec.}$$

From 9 meters or 29.5 feet, the velocity at impact is,

$$V = \sqrt{2gh} = \sqrt{2(32.16)(29.5)} = 43.5 \text{ ft/sec.}$$

Since $V_{cr} > 43.5$ ft/sec, no capsule failure should result.

D. PERCUSSION

The capsule should maintain its structural integrity after an impact where seven kilograms of steel fall through a distance of one meter. The flat face of the falling body is 2.5 centimeters in diameter.

Since the diameter is 2.5 centimeters or approximately one inch in diameter, the falling body is of the same dimensional magnitude as the capsule. Hence, it does not fall in the category associated with a penetrating medium nor is there a significant concentrated load to cause adverse deflection or deformation. The response of the capsule should be the same as that resulting from a capsule impacting a flat surface. In order to evaluate the structural integrity of the capsule to withstand a percussion test, the energy available from the seven kilogram weight will be compared to the impact energy capability derived previously.

For seven kilograms through a distance of one meter, the available energy becomes,

$$E_{avail} = 1\left(\frac{39.37}{12}\right)\left(\frac{7000}{451}\right) = 50.9 \text{ ft.-lbs.}$$

From the impact analysis of Section B, the critical impact velocity was found to be 248 ft/sec. With a capsule weight of 68.6 pounds, the equivalent energy is,

$$E_{cr} = \frac{1}{2}\left(\frac{68.6}{32.16}\right)(248)^2 = 6.56 \times 10^4 \text{ ft-lbs.}$$

$$\therefore \quad E_{cr} >> E_{avail}$$

E. THERMAL SHOCK

When investigating the capability of ductile materials to thermal shock, ultimate failure is dependent upon the mechanism of thermal fatigue. That is, for materials such as Hastelloy C, failure from thermal shock only occurs after N cycles where N is quite large. The capsule is thick walled; therefore, there is no possibility of distortion or thermal buckling.

Assuming a ΔT of 1800 -32 or 1768°F, the maximum strain is,

$$\epsilon_{max} = \frac{\alpha \Delta T}{1 - \lambda}$$

$$= \frac{8.5 \times 10^{-6}(1768)}{1-0.3} = .0215 \text{ in/in.}$$

A strain of .0215 in/in is at least one magnitude below the strain to failure for Hastelloy C. It is also important to note that the solution heat treatment for Hastelloy C is a water quench where the material is heated to approximately 2200°F.

ATTACHMENT 1

COMPRESSION AND IMPACT CAPABILITY

MIN-K 1301

Min-K 1301 not only represents an effective thermal insulator but has desirable structural characteristics to protect RTG components from shock and impact environments. When evaluating impact conditions the strain energy capability of Min-K is useful to apply since the area under the stress-strain curve represents the energy capability per unit volume of material. Data available in the literature (Reference A-14 and others) has been limited to a stress level of approximately 300 psi. In reality, the material has a useful capability at considerably higher stress levels. In support of this statement two test programs were conducted to stress levels in the vicinity of 1000 psi.

The first test program involved the compression of three quasi-unrestrained samples of Min-K 1301. The samples were cylindrical disks of four inches in diameter and averaged about two inches in height. The ID of the test chamber was four inches with a piston diameter of 3.75 inches. Hence, the geometry and amount of restraint was simulated to the application of interest. Loads were applied in increments over a range from zero to 12,000 pounds. The resulting data is presented in the stress-strain form in Figure A-7.

During April of this year, two additional cylindrical specimens were tested in a fully restrained condition. The length and diameter were one inch and .943 inch, respectively. A hydraulic press and a Dillon mechanical

force gauge were utilized. The resulting stress-strain curve is shown in Figure A-8. Load was applied in steps of approximately 28 pounds. Beyond approximately 140 psi, a load relaxation was observed during the interval of time (5 - 10 seconds) required to obtain the displacement readings. However, for dynamic or impact evaluations, this load relaxation should have little or no significance. All tests were performed at room temperature.

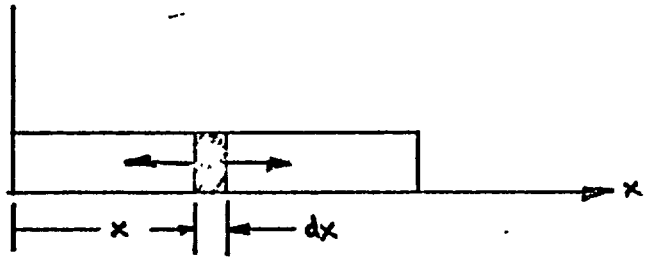
ATTACHMENT 2

IMPACT - STRESS WAVE PROPAGATION

Development of the One-Dimensional GDE (Elastic):

Dependent Variables : σ, ϵ , v

Independent Variables : x, t



Consider the prismatical bar shown of uniform cross-section. The force at x is,

$$F\Big|_x = \sigma A$$

At x + dx, the force is,

$$F\Big|_{x+dx} = \sigma A + \frac{\partial \sigma A}{\partial x} dx$$

$$= A\left[\sigma + \frac{\partial \sigma}{\partial x} dx\right]$$

Equating the net force equal to the element inertia,

$$A\left[\sigma + \frac{\partial \sigma}{\partial x} dx\right] - \sigma A = (\rho A\, dx)\frac{\partial^2 u}{\partial_t{}^2}$$

$$\therefore \frac{\partial \sigma}{\partial x} = \rho \frac{\partial^2 u}{\partial_t{}^2}$$

From Hookes' Law and the definition of strain,

$$\sigma = E\epsilon \qquad \epsilon = \frac{\partial u}{\partial x}$$

Therefore,

$$E \frac{\partial \epsilon}{\partial x} = \rho \frac{\partial^2 u}{\partial_t^2}$$

$$E \frac{\partial\left(\frac{\partial u}{\partial x}\right)}{\partial x} = \rho \frac{\partial^2 u}{\partial_t^2}$$

$$\frac{\partial^2 u}{\partial_x^2} = \frac{\rho}{E} \frac{\partial^2 u}{\partial_t^2}$$

However, the speed of sound within the material is defined as $c = \sqrt{\frac{E}{\rho}}$. Thus, the general differential equation becomes the wave equation,

$$\boxed{\frac{\partial^2 u}{\partial_t^2} = c^2 \frac{\partial^2 u}{\partial_x^2}}$$

The general solution has the form,

$$u = f(x + ct) + f_1(x-ct)$$

This represents two waves traveling along the x axis in opposite directions with constant velocity c. f and f_1 are determined by initial condition at t = o.

Example:

Initial conditions: $u\Big|_{t=o} = F(x)$

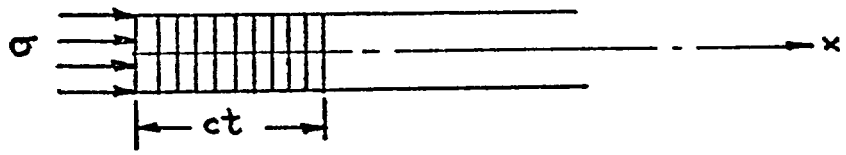
$$\frac{\partial u}{\partial t}\Big|_{t=o} = o$$

$$u\Big|_{t=o} = f(x) + f_1(x) = F(x)$$

$$\frac{\partial u}{\partial t}\Big|_{t=o} = c\,[f'(x) - f_1'(x)] = o$$

$$\therefore f(x) = f_1(x) = \frac{1}{2} F(x)$$

The initial displacement will be split into halves and propagated as waves in two opposite directions.



For the shaded zone, the decrease in lengths is $\epsilon\,(ct)$.

Particle velocity is distance/time.

$$\therefore v = \frac{\epsilon\,(ct)}{t} = \epsilon c.$$

Derivation of c:

Momentum of shaded portion of bar $= A\,c\,t\rho v$

Impulse of shaded portion of bar $= A\,\sigma t$

Equating impulse and momentum, (Ft = mv)

$$A\sigma t = A c t\, v$$

$$\sigma = c\rho v$$

$$\frac{Ev}{c} = c\rho v$$

$$\Longrightarrow \quad c = \sqrt{\frac{E}{\rho}}$$

Stain energy = $\frac{A c t \sigma^2}{2E}$

Kinetic energy = $\frac{A c t \rho v^2}{2} = \frac{A c t \sigma^2}{2E}$

Obviously strain energy = kinetic energy.

Wave propagation:

At a free end, a compressive wave is reflected as a similar tension wave.

At a fixed end, a wave is reflected entirely unchanged.

Impact Critical Velocity

From Hooke's Law, the relationship of stress and strain is given by,

$$\sigma = E\epsilon = \frac{\partial \sigma}{\partial \varepsilon}\,\epsilon$$

However, $v = \epsilon c$

$$\therefore \sigma = \frac{\partial \sigma}{\partial \epsilon}\,\frac{v}{c} = E \cdot \frac{v}{\sqrt{\frac{E}{\rho}}} \qquad \text{(elastic)}$$

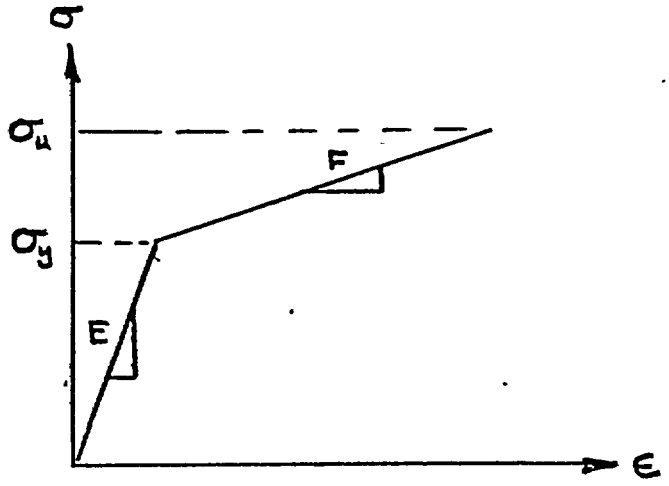
For elastic or plastic ranges,

$$\sigma = \frac{\partial \sigma}{\partial \epsilon}\,\frac{v}{\sqrt{\frac{\partial \sigma}{\partial \epsilon}/\rho}}$$

Thus, the particle velocity is,

$$v = \frac{\sigma}{\frac{\partial \sigma}{\partial \epsilon}} \sqrt{\frac{\partial \sigma / \partial \epsilon}{\rho}}$$

Consider an elastic linear strain hardening material where the elastic modulus is E and the plastic modulus is F as shown below.



The velocity may be subdivided into two parts, elastic velocity up to yield and plastic velocity.

$$v = V_E + v_o$$

$$\therefore \quad v = \frac{\sigma_y}{E}\sqrt{\frac{E}{\rho}} + \frac{\sigma_u - \sigma_y}{F}\sqrt{\frac{F}{\rho}}$$

$$\boxed{v = \frac{\sigma_y}{\sqrt{\rho E}} + \frac{\sigma_u - \sigma_y}{\sqrt{\rho F}}}$$

When taken to failure, σ_u then $v = v_{cr.}$ where $v_{cr.}$ is the critical impact velocity.

Another approach begins with the definition of wave velocity where,

$$c = \sqrt{\frac{\partial \sigma}{\partial \epsilon / \rho}}$$

Also $v = \epsilon c$

$$\therefore v = \epsilon \sqrt{\frac{\partial \sigma}{\partial \epsilon / \rho}}$$

$$= \int_o^{\epsilon} \sqrt{\frac{\partial o}{\partial \epsilon / \rho}}\, d\epsilon$$

When $v = v_{cr.}$, a plot of ϵ vs $\frac{\partial o}{\partial \epsilon / \rho}$ will produce an area under the curve. The area between o and ϵ_u represents the critical velocity.

APPENDIX B

THERMAL ANALYSIS

I. HYPOTHETICAL ACCIDENT FIRE ANALYSIS

A. SUMMARY

The SENTINEL 100F generator is shown to be capable of experiencing a standard transportation fire without impairing its basic structural integrity. The biological shield and fuel capsule will remain intact and at temperatures well below their respective melt temperatures for at least a period of three hours after a standard one-half hour transportation fire accident. Although the internal temperatures are still slowly rising three hours after the fire, fuel containment is assured for an indefinite period even without artificial external cooling.

The analyses presented herein gives predicted temperatures for normal operation, operation on short circuit in a 130°F ambient with solar load, and operation on open circuit in a standard transportation fire for two cases. The two fire cases presented include one in which the heat of fusion of the aluminum housing is included and one in which it is neglected. Critical component temperatures are compared in Table B-1.

One additional case (Case 4) was examined. This case consisted of the finned head of the generator being buried in the earth as a consequence of an accident. No credit was taken for heat transfer to the ground. For the conditions given for Case 4, the resulting steady state temperature for the fuel capsule was calculated to be 1724°F.

TABLE B-1

PREDICTED VS CRITICAL** COMPONENT TEMPERATURES

Component	Critical Temp.(°F)	Predicted Temperatures * Case 3a(°F)	Case 3b(°F)
Fuel Liner	2550	1812	1832
Fuel Capsule	2320	1606	1645
Biological Shield	6170	1416	1456

* 3 hours after a one-half hour fire

** The liner is not a critical component. It is used at the discretion of the fueling facility. If not used, the fuel capsule temperatures shown on Table B-1 will not be appreciably affected.

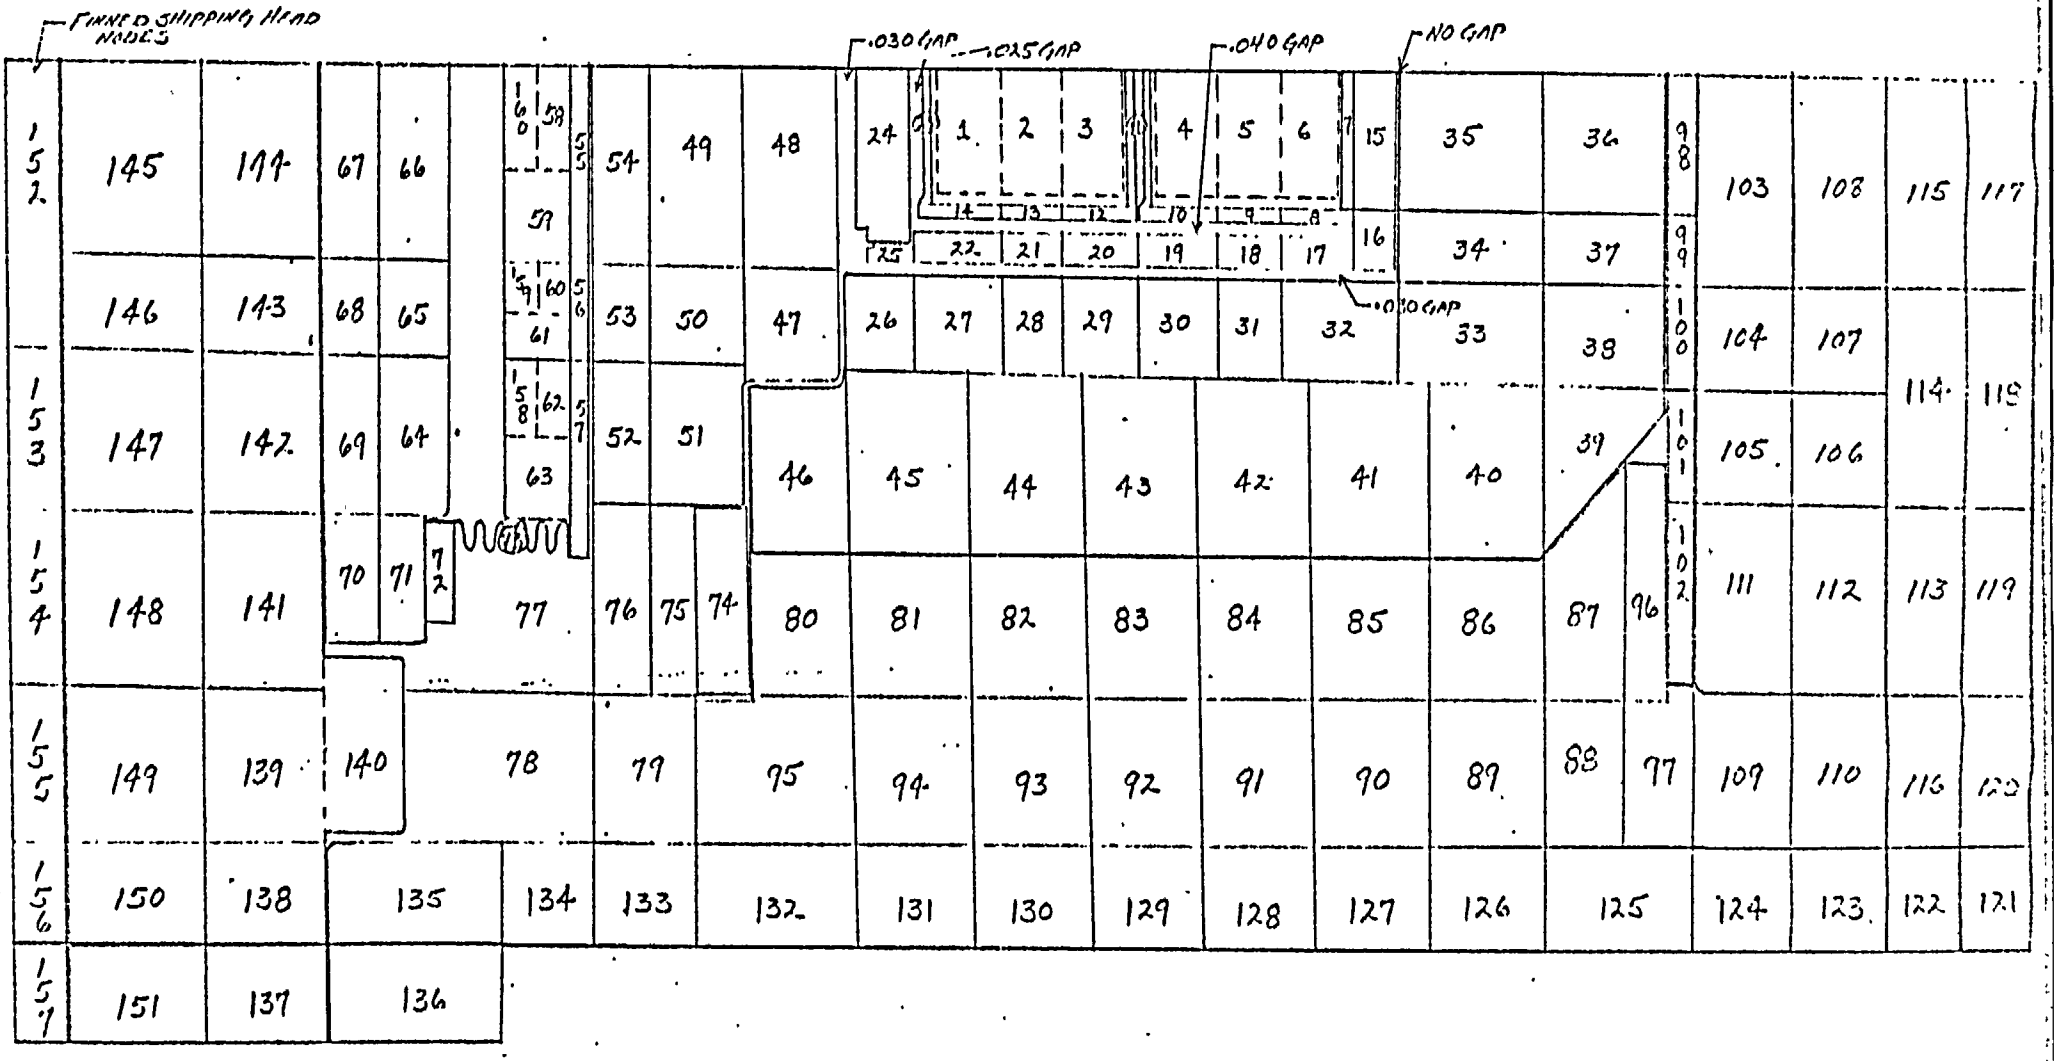
NOTE: Case 3a - includes heat of fusion of aluminum housing

Case 3b - neglects heat of fusion of aluminum housing

B. DESCRIPTION OF ANALYSIS

1. Thermal Model

The thermal model nodal map used for computer analysis of the SENTINEL 100F generator is presented in Figure B-1. Assuming symmetry about the cylindrical axis the generator is divided into 160 nodes plus node 161 which is used to represent the ambient heat sink. The thermoelectric module is approximated by nine nodes, six represent the thermoelectric elements and three represent the module insulation. The conductance values of the 96 thermoelectric elements are "dummied" to agree with the results of Teledyne Isotopes' thermoelectric code runs for these type elements. Conductances at key interfaces such as the biological shield-to-module hot plate interface, the hot plate-to-hot junction interfaces, cold junction-to-module heat sink interfaces and module heat sink-to-generator head interface are based on previous experience with SENTINEL generators utilizing hardware of similar design. To be conservative maximum gaps between the biological shield and the capsule outer wall, and between the capsule inner wall and the liner outer wall were assumed. Heat transfer through these gaps is considered to be by radiation and conduction through the argon gas. The inert gas in all gaps, insulation, and the module is assumed to be 100 percent argon. Radiation and natural convection are assumed at all external surfaces. For convection and radiation from the finned shipping head, the heat transfer coefficients used are based on the results of heat rejection tests conducted at Teledyne Isotopes on a typical finned head configuration.



161 = SINK NODE

SENTINEL 100F. NODAL MAP

FIG. B1

2. Conditions Analyzed

In order to insure the validity of the thermal model, the generator steady state temperature map and heat balance was determined for normal operating conditions as follows:

Case 1 - Normal Operation

Nominal Fuel Inventory	2100 watts
Electrical Power Output	150 watts
Ambient Temperature	75°F

No Solar Load

Finned Shipping Head in Place

The nodal temperatures obtained from this analysis are presented in Attachment 3, case 1, for comparison with the results of the transient fire accident analysis.

The second case analyzed consisted of determining the nodal temperature map and heat balance for the generator under typical shipping conditions which would exist prior to an accidental fire. In this case, the generator is normally on short circuit and the ambient temperature may be as high as 130°F. For additional conservatism it was assumed that the fuel inventory was 2500 watts which represents a practical limit to the inventory which could be loaded into this size capsule if a higher power density fuel form were to be used. The conditions thus assumed for the pre-fire case are as follows:

Case 2 - Pre-Fire Condition

Fuel Inventory	2500 watts
Short Circuit Condition, $P_{(e)} \neq 0$	
Ambient temperature	$130^{\circ}F$
Solar Load (uniform)	65 BTU/hr-ft^2
Finned Shipping Head in Place	

The resulting equilibrium nodal temperatures from the above case were used as input conditions for the fire accident analysis.

The final case analyzed was the hypothetical accidental fire condition. For this case, it is assumed that the thermoelectric module is immediately on an open circuit condition. The heat flux to all external surfaces of the generator was assumed to be that radiated from a $1475^{\circ}F$ source having an emittance of 0.9 for a period of 30 minutes. During the 30 minute fire simulation, reradiation from the exposed surfaces at an assumed emittance of 0.8 was permitted but convective cooling was assumed to be zero. At the end of the 30 minute fire, natural convection to a $130^{\circ}F$ ambient sink is restored, and a solar load is applied to all external surfaces. The nodal temperatures are then determined for a subsequent three hour period following the fire. The conditions used for the fire accident analyses were as follows:

Case 3 - Transportation Fire Accident

Fuel Inventory 2500 watts.

Open Circuit Operation, P(e) = 0

Fire: 1475°F radiation source, emissivity = 0.9

uniform impingement on all external surfaces

Exposure to Fire = 30 minutes

External Surfaces - Emittance = 0.8

Post Fire: Ambient Temperature = 130°F

Solar Load (uniform) 65 BTU/hr-ft^2

Three (3) Hour Period of Exposure

Case 4 was defined as a result of a transport accident where the finned head of the generator is embedded into the ground. The conditions used for this analysis were as follows:

Case 4 - Partial Burial Condition

Fuel Inventory = 2300 watts

Open Circuit Condition, P(e) = 0

Ambient Temperature = 130°F

Solar Load (uniform) = 65 BTU/hr-ft^2

Finned Head Buried

3. Computer Code

The four cases discussed above were analyzed using Teledyne Isotopes Thermal Analyzer Program called TAP 3. The TAP 3 program is a digital computer code (Fortran extended) which solves three-dimensional

transient heat transfer problems through the use of networks of conductors and capacitors. Steady state problems are also readily solved using this program by assigning zero values to the capacitors and running the transient calculation until a heat balance is achieved.

This code is extremely flexible for heat transfer problems in that each of the parameters (i.e., temperature, internal or external heat generation, capacity, and conductance) can be made to depend upon time or any of the other parameters in the network in any desired manner. This makes possible the solution of problems involving variable material properties, phase changes, ablation, convection and radiation. A programming feature within the code allows the automatic removal of melted or ablated surface nodes and automatic switching of external heat inputs, radiation and convection functions to the nodes beneath the removed ones. The code solves the heat diffusion equation by a forward finite difference technique.

The code is a descendant of the Lockheed Thermal Analyzer Program, and has been used in various forms throughout the Industry by companies such as Lockheed, North American Aviation, Atomics International, S&ID, and Rocketdyne Divisions. (See References B-1, B-2 and B-3.) Teledyne Isotopes' version of the code was originally obtained from the Atomics International Division of NAA, Inc. and has been revised and improved since that time.

The material properties used for the analysis described herein are presented in Attachment 4, along with other pertinent assumptions.

4. Discussion of Results of Transport Fire and Burial Analysis

Analysis of the fire accident case is complicated by the presence of the aluminum housing in the SENTINEL 100F design. The aluminum surface nodes possess considerable heat capacity in the form of latent heat of fusion. Since previous analyses have often neglected this energy absorbing potential of the housing under the assumption that it is conservative, it was decided to conduct the analyses of the SENTINEL 100F unit both ways to determine if this actually was a conservative approach. It was felt that the immediate removal of surface nodes upon their reaching melting temperature removes a large reservoir of thermal energy from the external nodes. The inclusion of this reservoir in the analysis, it was felt, might actually drive the internal temperatures higher during the post-fire-soak period if not removed. Therefore for the first fire case analyzed (see Case 3a, Attachment 3, and Figure B-2), only those nodes which completed their phase change were removed from the problem. The results of this analysis show that only one node (Node 121), a corner node, actually completely melted. This node melts because the fire heat flux is assumed to be uniformly impinging on all external surfaces (very conservative) and the corner node is thus exposed to the heat flux on two sides (sides and bottom). This fact coupled with the fact that it cannot conduct the heat away from this corner as readily as, for example, the upper corner node (Node 157) is able to, results in a complete melt of this node. As shown in Attachment 3 all the external aluminum nodes reach melt temperature and partially melt

during the one-half hour fire period except three of the finned head nodes. For the finned head nodes, the volume of the fins was neglected in determining the heat capacity of these nodes during the fire. Table B-1 presents a comparison of the predicted maximum temperatures (three hours after the fire) of certain critical materials of the generator with their melt temperatures. Three hours after the end of the fire, the external surface nodes are cooling down but the majority of the internal nodes are still slowly rising. Figure B-2 presents a temperature history of some pertinent nodal temperatures for this case.

The second fire case analysis, Case 3b, was conducted by removing the aluminum nodes from the problem as soon as they reached a melt temperature of 1140°F. The first nodes reached melt temperature about 18+ minutes into the fire period for the model shown in Figure B-1. Although most of the exterior aluminum nodes reached melt temperature during the fire period and were removed from the problem, very few of the second layer of aluminum nodes actually reached melt temperature except the bottom nodes 113 through 116. At the end of the fire period, housing nodes 138 through 150, nodes 152 through 154 and the module heat sink nodes 64 through 71 had not reached melt temperature. Figure B-3 presents a temperature history of some pertinent nodal temperatures for Case 3b. It should be noted that this case resulted in internal component temperatures after three and one-half hours (i.e., liner, capsule and biological shield) which are from 20 to 40°F higher than the first case,

Case 3a. Therefore, it appears that, for all practical purposes, from a safety standpoint, the assumption of either case is justified for this type of analysis.

The burial case resulted in a steady state temperature of 1724°F (max.) for the fuel capsule. The fuel capsule was used since its melt temperature is ~2500°F compared to ~6000°F for the shield. It should be noted that the initial conditions, such as no credit taken for heat transfer to the ground and the maximum inventory being used, represent a conservative approach.

5. Conclusions

It is concluded that the SENTINEL 100F generator is capable of surviving a standard transportation fire without damage to either the biological shield or the fuel capsule and thus fuel containment is assured.

C. SUPPLEMENTARY THERMAL INFORMATION R4

Included in this section is additional thermal data which was originally supplied as supplements dated November 30 and December 20, 1971 and January 19, 1972 at the request of the licensing agency. For clarity, all written correspondance has been included. The section begins with the request from the licensing agency - letter DML:RHO (19-01398-34) and continues in chronological order with the data submittals and their cover letters. Only Attachment B (TAP 3 User's Manual) of letter TPS-CNY-254 (supplement dated 20 December 1971) has been omitted as explained in the Preface of this report.

Gentlemen:

This refers to your application dated August 10, 1971, pertaining to the Sentinel 100F thermoelectric generator. In connection with our review of this application, please submit the information identified in the enclosure to this letter.

A word of explanation is in order concerning your interpretation of the thermal analysis requirements of Appendix B of Part 71. The transient analysis was followed for only three hours after the end of the thermal test even though the temperatures of the fuel capsule were still rising. These temperatures should have been followed until they started to fall or reached steady state. However, it is true that in this case there is little probability that the fuel capsule temperature will rise much further if indeed the temperature at three hours is only 1646°F.

Apparently, the misinterpretation arose from the statement in Appendix B in 10 CFR 71 which states that a package shall not be cooled artificially until three hours after the test period unless the temperature within the package begins to fall in less than three hours. This statement in the regulation is related to extinguishing the fire on the outside of a package, as from a wooden overpack, and does not relate to cooling of an internal heat source.

Sincerely,

D. A. Nussbaumer

Enclosure to Letter Dated NOV 15 1971

1. References for all relevant thermal properties for all the materials listed on pages 84 through 86. Information concerning the fuel, bioshield, MIN-K, glassrock, and the emissivities of all materials, is essential to our review.

2. Descriptions of experiments, computer code, and calculations used for evaluating the effective thermal properties of the thermoelectric elements.

3. Description of tests and calculations used to evaluate the effective conductances of key interfaces as listed on page 88.

4. Does the effective conductivity of the thermoelectric elements given on page 84 include the interface resistances given on page 88? Please explain.

5. The thermal properties for nodes 55 through 73 and 158 through 160 as a function of temperature.

6. Description of correlations and values used for all the boundary conditions (radiation and natural convection heat transfer coefficients).

7. Description of tests conducted for evaluating the heat transfer from the finned shipping head. Also, state the fin dimensions and calculate the actual external surface area.

8. Justification for the value of 65 $Btu/hr \cdot ft^2$ used for the solar heat load. State the value of solar absorptivity used for the cask surface.

9. Two copies of the latest users manual for the TAP3 computer program. Please indicate and explain all revisions to the program made since the manual was published.

10. Explanation as to how the TAP3 program handles both fire and internal gap radiative heat transfer. The table on page 86 indicates a constant heat flux from 5°F to 1800°F. The fire heat flux is a function of the cask surface temperature and is normally calculated by the program.

Mr. D. A. Nussbaumer, Chief
Fuel Fabrication and Transportation Branch
Division of Materials Licensing
U. S. Atomic Energy Commission
Washington, D. C. 20545

Gentlemen:

In response to your letter of 15 November 1971, reference DML:RHO (19-01398-34), we are submitting the enclosed data. Each item has been answered individually; but, because of the general nature of some requests, it has been necessary to limit the reply to what we believe to be the pertinent facts. Complete documentation would require a very lengthy report.

The TAP3 Computer Program Users Manual (Item 9 in your letter) is currently being rewritten to incorporate all existing amendments. It is expected that this work will be completed within the next two weeks. Two copies will be forwarded to you as soon as the manual becomes available.

We trust that this data will meet your requirements. If you have further questions, please do not hesitate to ask.

Sincerely,

NUCLEAR SYSTEMS DIVISION

C. N. Young

** The tungsten biological shield is chrome plated on all inner & outer surfaces.

2. Descriptions of experiments, computer code, and calculations used for evaluating the effective thermal properties of the thermoelectric elements.

The thermoelectric code used by Teledyne Isotopes NSD is called "VINCE-TOM" and is based upon the evaluation of the following differential equation for the temperature distribution through the T/E elements:

$$\frac{d}{dx}\left(k A \frac{dT}{dx}\right) + \frac{I^2 \rho}{A} + \tau I \frac{dT}{dx} = 0$$

This equation considers all heat transport effects including conduction, Joule heating and Thompson heating and is solved by the code for both elements of the couple. The code also calculates the heat required for the thermoelectric elements, and the electrical power output for any number of couples in any series, parallel or series-parallel configuration for any external load situation. The major inputs to the code are couple geometry and material properties. The property data for the 2N/TAGS/SnTe materials system used in the SENTINEL 100F module is well known and documented. These materials have been utilized in a number of the SNAP 19, Viking and Pioneer space generators, and in the SNAP 29 generators. Numerous tests and correlations of generator and couple performance have established the validity of the thermoelectric property data and the ability of the code to predict their performance.

The 2N/TAGS/SnTe couple used in the SENTINEL 100F is a single doped N-element and a segmented P-element. Since the thermal conductivity of these three materials exhibit different shaped curves as a function of temperature, the only practical way to define the conductance for the thermal code is to use the predicted heat flow and ΔT_{HJ-CJ} from the T/E code; i.e.,

$$C = \frac{Q_{T/E}}{\Delta T_{HJ-CJ}}$$

3. Description of tests and calculations used to evaluate the effective conductances of key interfaces as listed on page 88.

The interfaces listed on page 88 exist on nearly every SENTINEL and SNAP generator built by Teledyne Isotopes and this includes some 25 SENTINEL types and a dozen SNAP type generators.

The hardware in each is practically identical except for size. The properties of the thermoelectric materials are well know using

these in our thermoelectric code, good agreement is found between the electrical power generated and predicted at measured hot and cold junction temperatures in a generator configuration. Therefore, the heat flow through the thermoelectric elements is known. Since we also measure hot plate temperature and fin root temperature on our generators, the interface conductances are readily calculated.

In the past, we have conducted heat transfer tests on instrumented cold end hardware and these were found to be in good agreement with values measured in the generator configuration. Currently, we have been testing a partial mock up of the SENTINEL 100F T/E module. This module is fully instrumented to provide cold end temperature drops using the exact hardware that will exist in the SENTINEL 100F module. Analysis of this data indicates that the cold end conductance will be even higher than assumed for the fire analysis so the initial internal temperatures will be lower than those presented.

In addition to the above, an in-house program was conducted about six months ago in which the effective conductance of various generator type interfaces were evaluated. These tests included evaluations of dry interfaces and interfaces employing various types of thermal greases or compounds. The grease currently being employed is Dow Corning DC-340 thermal compound.

4. Does the effective conductivity of the thermoelectric elements given on page 84 include the interface resistances given on page 88? Please explain.

No, it represents the effective conductivity of the T/E elements on open circuit. The interface resistances presented on page 88 represent our experience with the various hardware interfaces presented. The conductances are based on either the common area between the nodes involved or on the element area in the case of the hot plate-to-hot junction and cold junction-to-module heat sink conductances.

5. The thermal properties for nodes 55 through 73 and 158 through 160 as a function of temperature.

Nodes (55, 56, 57), 72 and 73 are the module hot plate, bellows and lower ring of bellows assembly and are 300 series stainless steel. Properties are given in tables presented in INSD-3080 attachment 4. Nodes 58, 60, 62 and 158, 159, 160 represent the thermoelectric elements. Nodes 58, 60 and 62 are the hot junctions and 158, 159 and 160 are the cold junctions. Nodes 59, 61 and 63 represent the Min-K insulation (inside the sealed module) which surrounds the thermoelectric elements and is argon gas filled as is the Min-K insulation in the generator.

For normal operation; i.e., steady state, with electrical power being generated, the conductance of the thermoelectric elements and the electrical power generation is varied until a match is obtained between the results of the thermoelectric code runs and the thermal code runs. The electrical power is removed at the cold junction in the thermal model since this is thermal energy which has been converted to electrical energy. The flow of current through the thermoelectric elements increases the effective conductance of the elements so it is not possible to use straight conductivity values for the elements under normal operation. For the fire analysis, open circuit is assumed so there are no current effects.

6. Description of correlations and values used for all the boundary conditions (radiation and natural convection heat transfer coefficients).

For natural convection from the exterior surfaces of the housing, the following correlations were used:

$$h = C \left(\frac{\Delta T}{L}\right)^n$$

where C = .12 for downward facing and horizontal surfaces
C = .29 for vertical surfaces and upward facing horizontal surfaces
n = 0.25

These equations were programmed into the code runs. Natural convection was only assumed for the steady state runs and for the transient periods after the fire.

The radiation heat transfer from the external surfaces was calculated by the code using the tabular values of emissivity and radiating to 130°F ambient in the case of the fire analysis.

7. Description of tests conducted for evaluating the heat transfer from the finned shipping head. Also, state the fin dimensions and calculate the actual external surface area.

This question is not pertinent to the fire analysis but only to the steady state cases which were analyzed. In the case of the fire analysis, the volume of the fins was neglected as stated in INSD-3080. The justification for this is that because of the very large exposed surface area of the fins, the fins will reach melt temperature in about 30 seconds if the fire heat flux is assumed to impinge uniformly on their total surface area. Therefore for the fire analysis only the base of the finned shipping head was included in the model.

For the steady state analyses, the performance of the finned head was based on the results of tests of a typical finned head configuration over a range of fin root temperatures. For this test, the test apparatus consisted of a finned shipping head electrically heated under the base by an insulated heater plate about the size of the module. The parasitic losses were determined and found to be a very small percentage (approximately 0.8 percent) of the total electrical heat input. The test results were analyzed and it was determined that the effective heat transfer coefficient over the range of fin root temperatures of interest (100 to 225°F) could be expressed as $h_{eff} = 0.11 (T_{FR} - T_{AMB})^{0.34}$ BTU/HR-°F-Ft^2. This equation was programmed into the steady state code runs to simulate the performance of the finned shipping head. The fin configuration consists of 48 anodized aluminum fins, 10 inches high and 1/8 inch thick, located in a 24.25" diameter area and having a total surface area of 125 square feet.

8. Justification for the value of 65 Btu/hr· ft^2 used for the solar heat load. State the value of solar absorptivity used for the cask surface.

The solar heat load was determined as follows. From Reference (1)*, a conservative value of direct solar irradiation on a surface normal to the sun's rays at the earth's surface on a cloudless day was selected as 320 BTU/HR-Ft^2. Since no more than half of the total generator surface area (actually less) can be exposed to the direct rays of the sun this irradiation was reduced to one-half or 160 BUT/HR-Ft^2. A value of absorptance for solar radiation of 0.4** for the surface was assumed.

$$\frac{Q_{solar}}{A} = 320\ (.5)(.4) \cong 65 \text{ BTU/HR-Ft}^2 \text{ absorbed}$$

* Reference (1): Heat and Mass Transfer, E. R. G. Eckert & R. M. Drake, Jr., McGraw-Hill Book Co., Inc. 1959.

** The SENTINEL 100F housing is protected by an epoxy-polyamide coating system.

9. Two copies of the latest users manual for the TAP3 computer program. Please indicate and explain all revisions to the program made since the manual was published.

To be forwarded under separate enclosure.

10. Explanation as to how the TAP3 program handles both fire and internal gap radiative heat transfer. The table on page 86 indicates a constant heat flux from 5°F to 1800°F. The fire heat flux is a function of the cask surface temperature and is normally calculated by the program.

The table on page 86; i.e., Table 21, which specifies the fire heat flux in BTU/Ft^{2}Sec should have the abscissa labeled as time instead of temperature. The time is given in seconds and defines the fire as starting at 5 seconds and continuing until 1800 seconds. From 1800 to 1805 the fire heat flux is assumed to decay to the solar heat flux. These tables were spliced together from the computer print out and the time label for this table was inadvertently left out. The abscissa for all the other tables given on pages 84 to 86 is temperature as indicated.

The fire heat flux shown in Table 21 is the heat flux impinging on the exterior surfaces. In the TAP3 program, this heat input is handled by assuming that this heat is internally generated in the surface nodes. The net heat flux is of course a function of the housing surface temperature and is calculated by the program. As can be seen, this method of handling the fire heat input is conservative.

The method by which TAP3 handles internal gap radiative heat transfer is controlled by the programmer. For the analyses presented, equations are programmed into the code which evaluate the emissivity of each of the two surfaces from the tabular input data as a function of their respective temperatures, combine these into an effective emittance or overall exchange factor as desired, and calculate the radiation heat transfer in the normal manner; i.e.,

$$Q_{rad} = F_{12}A_1 \quad \sigma(T_1^4 - T_2^4)$$

where F_{12} is the overall interchange factor.

Attention: Mr. D. A. Nussbaumer, Chief
Fuel Fabrication and Transportation Branch

Gentlemen:

This letter is intended to furnish further data in support of our SENTINEL 100F license application. Please refer to the following references:

a. DML:RHO (19-01398-34) dated 11/15/71, letter U.S. Atomic Energy Commission to Isotopes, Inc.
b. TPS-CNY-239 dated 11/30/71, letter Isotopes, Inc. to U.S. Atomic Energy Commission.

Attachment A amplifies our answers to questions 2 and 3 of reference a. The test data referenced has been taken largely from a special module evaluation test conducted especially for the SENTINEL 100F and therefore is directly applicable to this application. Data from the SENTINEL 8S program is also presented as further correlation between the code analysis and generator performance. Except for thermal and electrical power, the generators are quite similar. The Dow Corning thermal grease is used to reduce the gradients across the thermal interfaces. As mentioned, we have considerable operating experience with this compound.

Attachment B is a copy of the users manual for the TAP-3 computer program as promised in reference b.

Sincerely,

NUCLEAR SYSTEMS DIVISION

C. N. Young
Project Engineer
Terrestrial Power Systems Division

Enclosures: (2)

ATTACHMENT A

ADDITIONAL DATA FOR QUESTION 2 & QUESTION 3 OF REFERENCE a:

In order to elaborate further on the ability of the thermoelectric computer code used by INSD to predict the performance of the thermoelectric module, the following data is offered. Six of the couples fabricated for the SENTINEL 100F module were drawn from the production run and assembled and bonded into a 6-couple module for performance and life testing. The 6-couple module was designed to be tested in an electrically heated test fixture specifically tailored for this test. The module itself was fully instrumented, having four hot junction thermocouples, three cold junction thermocouples as well as voltage taps on every element. The test fixture was provided with cold end hardware identical to that being utilized in the 100F module; i.e., pistons, springs and aluminum heat sink. The cold end hardware was also instrumented with thermocouples on the pistons and the heat sink so that the cold end hardware temperature drop could be measured directly. Prior to installation of the module, the parasitic heat losses through the fixture were determined experimentally so that the heat flow through the thermoelectric elements could also be determined from the test data. Parametric testing of this module was performed some months ago and since then it has been on a life test. Arbitrarily selecting one of the parametric data points, it was shown that the performance measured could be predicted by the code. The measured data point for example is shown below:

Hot junction temperature (avg.)	993°F
Cold junction temperature (avg.)	226°F
Current	20.08a
Load Voltage	0.486 VDC
Open circuit voltage	1.016 VDC
Load resistance	24.203 mΩ
Internal resistance	26.394mΩ
Electrical power output	9.76 w(e)
Electrical heat input	157 w(th)
Piston temperature (avg.)	213°F
Heat sink (avg.)	208°F
∴Cold end $\Delta T_{CJ-H/S}$	18°F
Heat to T/E elements (based on parasitic heat loss curve)	122.0 w(th)

When the boundary conditions shown above; i.e., hot and cold junction temperatures and external load are used as inputs to the T/E code, the predicted heat flow to the T/E elements is 121.1 watts which is within less than 1% of the measured heat flow. The conductance of the T/E elements of the module is thus established by computing the ratio of the heat flow to the thermoelectric elements to the temperature drop from the hot-to-cold junction.

The SENTINEL 100F was designed to produce 150 w(e) at B. O. L. when operating at hot junction/cold junction of 1000/225°F. At these conditions, the predicted heat flow to the thermoelectrics at the matched load condition is 1800 watts thermal. Thus the conductance is 7.932 Btu/hr-°F. Since the conductance is essentially $\frac{kA}{L}$, any combination of these parameters which give the proper conductance can be used in the thermal model. For the analyses presented, we elected to hold the conductivity constant (in the tables) and vary the A/L ratio and the electrical power output for the different operating conditions. The electrical power output is dumped to a heat sink at the cold junction in the thermal model. As a general rule, the effective conductance of the elements on short circuit (Pe = 0) and on open circuit (Pe = 0) is between 20 - 30% higher and lower respectively than when on load.

ADDITIONAL INTERFACE DATA

a. Cold End - As can be noted from the measured data presented earlier, the cold-end temperature drop (i.e., from the cold junction to the heat sink) is 18°F. The heat flowing through this cold end hardware is the heat to the thermoelectrics less the electrical power output or 122 - 10 watts = 122 watts. The conductance per unit area based on element area is thus

$$\frac{112\ (3.4152)(144)}{(18)(2.9316)} = \frac{Q}{\Delta T\ (Ael)} = 1044 \text{ Btu/hr-ft}^2\text{-}^\circ\text{F}.$$

Although conductances this high have been measured on some SENTINEL generators in the past, the fabrication tolerances of the parts making up the cold end hardware causes variations in cold end conductances. Therefore for the SENTINEL 100F analyses we elected to choose a more conservative (and more typical) value of cold end conductance of 425 Btu/ft^2-hr-°F as shown in INSD-3080, page 88.

b. Module Heat Sink-To Housing Lid Interface - This interface is an aluminum-to-aluminum interface with Dow Corning 340 grease in the interface. Interface tests were conducted at INSD in March and April of 1971 using a calibrated test apparatus on the effects of various types of thermal greases or compounds on the conductance of aluminum-to-aluminum interfaces when compared with a dry interface. The test apparatus was designed to measure the heat flow through the interface and the temperature drops. The tests were conducted using plain silicon grease, aluminum grease, Dow Corning 340 grease and others and were conducted over a range of interface heat fluxes and interface temperatures. The Dow Corning 340 grease, which is also utilized in our standard TELAN generators, was found to be as good as any of the compounds tested and better than most. The value of conductance shown in INSD-3080, page 88, of 1500 Btu/hr-ft^2-°F is typical of measurements

made during these tests. The tests encompassed interface heat fluxes as high as 45 watts/in^2 which are considerably higher than anticipated for this interface. The interface pressure (mechanical) for the tests was low and of the order of 25 - 30 psi which is typical for these interfaces. This data is also applicable to the interface between the finned shipping head and the housing lid.

c. Biological Shield - This path encompasses four interfaces as well as the module hot plate. These are the interface between the biological shield and hot plate, hot plate and getter, getter and mica, and the mica to hot shoe interface. The exact breakdown of the total temperature drop between the biological shield and hot junction is not known, but the overall effect has been measured on several generators. For example, the SENTINEL 8S electrically heated generator was instrumented with thermocouples on the biological shield, hot junction, cold junction, etc. and was tested extensively. The table shown below compares the data taken on the SENTINEL 8S with the assumptions used in the thermal model for the SENTINEL 100F (see case 1, INSD-3080).

	8S	100F
Q_{inv}(w)	301	2100
Biological Shield T(^{o}F)	959	1090.6
Hot Juntion (^{o}F)	900	1001.6
Total ΔT (^{o}F)	59	89
Interface Q(w)	250	1873
Common Area (in^2)	25.967	132.733
Effective Btu/hr-ft^2-^{o}F nonductance	80.25	78

The conductances shown in INSD-3080, page 88, for the module hot plate-to-hot junction and biological shield-to-hot plate inteffaces are obtained by making allowances for the conductances of the hot plate and biological shield portion of the path (based on published data), and assuming the individual interface ΔT to be one quarter of the total interface ΔT. As shown in the table above, the net result is to give an effective conductance close to that measured for the SENTINEL 8S.

d. Other Tests - In addition to the previous test data, each thermoelectric module is tested in a thermally calibrated electrically heated test fixture prior to installation in a fueled generator. This test is primarily intended to check the electrical performance without the restrictions required when using a radioactive heat source. However, it is instrumented for thermal evaluation also and, in fact, is verification for the radioactive fuel inventory selection.

Attention: Mr. D. A. Nussbaumer, Chief
Fuel Fabrication and Transportation Branch

Gentlemen:

This letter is to confirm thermal property data as relayed to Mr. R. Odegaarden by telephone as of this date. This data is in reference to Teledyne Isotopes' application for a SENTINEL 100F license, and amplifies our letter TPS-CNY-254 dated 12/20/71.

The thermal conductivity of the thermoelectric elements varies not only as a function of temperature but is also dependent upon the current flow through the elements. The current flow is a function of the mode of operation, and the effective conductivity for each mode is shown below.

Mode of Operation	Effective Conductivity of Elements Btu/ft-hr-°F
Normal	0.90
Short Circuit	1.2182
Open Circuit	0.8333

Sincerely,

COPIES SENT TO COMPLIANCE

393

APPENDIX C

ANALYSIS OF SHIELD LID ATTACHING BOLTS

R3, R4

This appendix provides analysis which addresses the loading of the bolts used to attach the shield lid to the body of the tungsten biological shield under conditions of impact froma 30 foot drop. The evaluation assumes the most critical angle of impact. Under highly conservative assumptions, the analysis shows a positive safety margin when the resultant stress is compared to the yield stress of the bolts. Thus, the analysis shows that the shield body, lid and fuel capsule configuration will remain intact given the drop environment. The balance of this appendix is as per Revision 3, dated October 22, 1971.

R4

ANALYSIS OF SHIELD LID ATTACHING BOLTS

It is assumed that the shield assembly impacts on the edge of the lid (Point 0) with the center of gravity of the shield body in line with the path of motion as shown in Figure 1. Although the edge of the shield plug has been cut back as shown, the point of impact may be considered to lie on the line AO. This is because the shield plug is immediately against the Min-K insulation which will allow the sharp edges to sink in making the effective point of impact on the line of action.

In the following analysis the shield plug is treated as a free body as shown in Figure 1. The analysis is based on static equilibrium, since the distribution is proportional for higher G loadings. In order for tension, T, to exist in the bolt there must be a separation between the body and the lid such that contact exists only at point C.

$OA = 13.17$ inches

$F_1 = 1267$ pounds

$F_2 = 263$ pounds

$F_3 = 73.4 \left(\frac{11.21}{13.17}\right)^2 = 53.2$ pounds

Solve for F_4 by taking moments about point O.

$$M_o = (1267)(1.067) - 263\,(5.022) - 53.2\,(3.940) + F_4\,(9.251)$$

$$F_4 = +19.30 \text{ pounds}$$

The positive sign indicates that the bolt is indeed in tension, and it is necessary to apply the proper G loading to determine if the bolts are adequate.

FIGURE WITHHELD UNDER 10 CFR 2.390

FIGURE C-1, SHIELD GEOMETRY

The G loading is given by the following equation.*

$$G = \frac{72}{t}\sqrt{h}$$

G = acceleration, g

t = shock rise time, milliseconds

h = drop height, inches.

The most severe condition given is for rigid steel against concrete, which, for a point (corner) impact, has a rise time of two milliseconds. The case under consideration is more like the condition of product case against one inch felt which has a rise time of 30 milliseconds for a point contact. The shield under consideration actually has three to four inches of fibrous insulation to cushion the impact. Looking at the worst case,

$$G = \frac{72}{2}\sqrt{(30)(12)} = 683 \text{ g}$$

Multiplying the g loading by the static loading in the bolt yields the potential loading in the bolt at impact.

$$P = (19.30)(683) = 13,182 \text{ pounds.}$$

The bolt is a 1/2-20 which has a tensile area, A, of 0.1597 square inch. The stress is:

$$S = \frac{P}{A} = \frac{13,182}{0.1597} = 82,542 \text{ psi}$$

The bolts are made from A-286 which has the following properties at 1000°F:

Ultimate stress	131,000 psi
Yield stress	88,000 psi

*Magner, R.T., "Design for Shock Resistances," Product Engineering Magazine

The margin of safety is:

$$MS = \frac{88,000}{82,542} - 1 = 0.066$$

Further, it should be noted that this analysis is highly conservative in that a very fast shock rise time has been used, and that the load has been reacted entirely in one bolt.

APPENDIX D

LIST OF DRAWINGS

R4

The following drawings are included with this report as part of the license application. These drawings are the current versions (as of June 1985). The packaging is constructed in accordance with these drawings:

010F10000	Sheets 1-3 (Rev. C), Generator Assembly 100F
010F20000	Sheets 1-2 (Rev. B), Fuel Capsule Assembly
010F70003	(Rev. A), Shield Body
010F70004	(Rev. A), Shield Plug
001-90064	Sheets 1-2, (Rev. A), Shipping Crate Sentinel RTG
001-90039	Sheets 1-4, (Rev. J), Pallet Assembly

NRC FORM 464 Part I (6-1998) | U.S. NUCLEAR REGULATORY COMMISSION

RESPONSE TO FREEDOM OF INFORMATION ACT (FOIA) / PRIVACY ACT (PA) REQUEST

FOIA/PA: ML073400251 2008-0006 | RESPONSE NUMBER: 1

RESPONSE TYPE: ☐ FINAL ☑ PARTIAL

REQUESTER: Amy Stattel

DATE: NOV 23 2007

PART I. -- INFORMATION RELEASED

☐ No additional agency records subject to the request have been located.

☐ Requested records are available through another public distribution program. See Comments section.

☑ APPENDICES A — Agency records subject to the request that are identified in the listed appendices are already available for public inspection and copying at the NRC Public Document Room.

☑ APPENDICES B & C — Agency records subject to the request that are identified in the listed appendices are being made available for public inspection and copying at the NRC Public Document Room.

☑ Enclosed is information on how you may obtain access to and the charges for copying records located at the NRC Public Document Room, 11555 Rockville Pike, Rockville, MD 20852-2738.

☑ APPENDICES B & C — Agency records subject to the request are enclosed.

☐ Records subject to the request that contain information originated by or of interest to another Federal agency have been referred to that agency (see comments section) for a disclosure determination and direct response to you.

☑ We are continuing to process your request.

☐ See Comments.

PART I.A -- FEES

AMOUNT * $

* See comments for details

☐ You will be billed by NRC for the amount listed.

☐ You will receive a refund for the amount listed.

☐ None. Minimum fee threshold not met.

☐ Fees waived.

PART I.B -- INFORMATION NOT LOCATED OR WITHHELD FROM DISCLOSURE

☐ No agency records subject to the request have been located.

☑ Certain information in the requested records is being withheld from disclosure pursuant to the exemptions described in and for the reasons stated in Part II.

☑ This determination may be appealed within 30 days by writing to the FOIA/PA Officer, U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001. Clearly state on the envelope and in the letter that it is a "FOIA/PA Appeal."

PART I.C COMMENTS (Use attached Comments continuation page if required)

The records identified on enclosed Appendix A are already publicly available in the NRC Public Document Room (PDR). We have enclosed a notice which provides procedures for obtaining records from the PDR. You may contact the PDR on (301) 415-4737, or toll free on (800) 397-4209.

NRC FORM 464 Part II (3-2006) U.S. NUCLEAR REGULATORY COMMISSION	FOIA/PA	DATE
RESPONSE TO FREEDOM OF INFORMATION ACT (FOIA) / PRIVACY ACT (PA) REQUEST	2008-0006	NOV 2 3 2007

PART II.A -- APPLICABLE EXEMPTIONS

APPENDICES: C

Records subject to the request that are described in the enclosed Appendices are being withheld in their entirety or in part under the Exemption No.(s) of the PA and/or the FOIA as indicated below (5 U.S.C. 552a and/or 5 U.S.C. 552(b)).

- ☐ Exemption 1: The withheld information is properly classified pursuant to Executive Order 12958.
- ☐ Exemption 2: The withheld information relates solely to the internal personnel rules and procedures of NRC.
- ☐ Exemption 3: The withheld information is specifically exempted from public disclosure by statute indicated.
  - ☐ Sections 141-145 of the Atomic Energy Act, which prohibits the disclosure of Restricted Data or Formerly Restricted Data (42 U.S.C. 2161-2165).
  - ☐ Section 147 of the Atomic Energy Act, which prohibits the disclosure of Unclassified Safeguards Information (42 U.S.C. 2167).
  - ☐ 41 U.S.C., Section 253b, subsection (m)(1), prohibits the disclosure of contractor proposals in the possession and control of an executive agency to any person under section 552 of Title 5, U.S.C. (the FOIA), except when incorporated into the contract between the agency and the submitter of the proposal.
- ☐ Exemption 4: The withheld information is a trade secret or commercial or financial information that is being withheld for the reason(s) indicated.
  - ☐ The information is considered to be confidential business (proprietary) information.
  - ☐ The information is considered to be proprietary because it concerns a licensee's or applicant's physical protection or material control and accounting program for special nuclear material pursuant to 10 CFR 2.390(d)(1).
  - ☐ The information was submitted by a foreign source and received in confidence pursuant to 10 CFR 2.390(d)(2).
- ☐ Exemption 5: The withheld information consists of interagency or intraagency records that are not available through discovery during litigation. Applicable privileges:
  - ☐ Deliberative process: Disclosure of predecisional information would tend to inhibit the open and frank exchange of ideas essential to the deliberative process. Where records are withheld in their entirety, the facts are inextricably intertwined with the predecisional information. There also are no reasonably segregable factual portions because the release of the facts would permit an indirect inquiry into the predecisional process of the agency.
  - ☐ Attorney work-product privilege. (Documents prepared by an attorney in contemplation of litigation)
  - ☐ Attorney-client privilege. (Confidential communications between an attorney and his/her client)
- ☑ Exemption 6: The withheld information is exempted from public disclosure because its disclosure would result in a clearly unwarranted invasion of personal privacy.
- ☐ Exemption 7: The withheld information consists of records compiled for law enforcement purposes and is being withheld for the reason(s) indicated.
  - ☐ (A) Disclosure could reasonably be expected to interfere with an enforcement proceeding (e.g., it would reveal the scope, direction, and focus of enforcement efforts, and thus could possibly allow recipients to take action to shield potential wrongdoing or a violation of NRC requirements from investigators).
  - ☐ (C) Disclosure would constitute an unwarranted invasion of personal privacy.
  - ☐ (D) The information consists of names of individuals and other information the disclosure of which could reasonably be expected to reveal identities of confidential sources.
  - ☐ (E) Disclosure would reveal techniques and procedures for law enforcement investigations or prosecutions, or guidelines that could reasonably be expected to risk circumvention of the law.
  - ☐ (F) Disclosure could reasonably be expected to endanger the life or physical safety of an individual.
- ☐ OTHER (Specify)

PART II.B -- DENYING OFFICIALS

Pursuant to 10 CFR 9.25(g), 9.25(h), and/or 9.65(b) of the U.S. Nuclear Regulatory Commission regulations, it has been determined that the information withheld is exempt from production or disclosure, and that its production or disclosure is contrary to the public interest. The person responsible for the denial are those officials identified below as denying officials and the FOIA/PA Officer for any denials that may be appealed to the Executive Director for Operations (EDO).

DENYING OFFICIAL	TITLE/OFFICE	RECORDS DENIED	APPELLATE OFFICIAL		
			EDO	SECY	IG
Samuel J. Collins	**Regional Administrator, Region 1**	**Appendix C**	✓		

Appeal must be made in writing within 30 days of receipt of this response. Appeals should be mailed to the FOIA/Privacy Act Officer, U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001, for action by the appropriate appellate official(s). You should clearly state on the envelope and letter that it is a "FOIA/PA Appeal."

NRC Reviewer:	David F. Limroth, Stephen W. Holmes		
Review Abstract:	License No. 19-01389-32 authorized research and development work with unsealed byproduct material in Building D at Middle River, Maryland. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces. The building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on November 3, 1994 indicate that the site is suitable for unrestricted use.		
Recommendations:	None.		

Summary: License No. 19-01398-32 was issued on December 9, 1964 authorizing research and development work with a variety of unsealed byproduct materials in Building D at the Martin Company's Middle River, Maryland facility. On September 4, 1968, License No. 19-01398-32 was transferred to Isotopes, Incorporated. The license was terminated on March 20, 1969; however, no record of a termination or confirmatory survey, transfer of material, etc., could be located. It appears that Building D was returned to Martin-Marietta at that time.

Information from various docket files indicates that a variety of activities with large amounts of byproduct, source, and special nuclear material were authorized at Building D at the Middle River facility. Activities with licensed material at Building D ceased prior to 1970. License No. SNM-1192 was issued to Martin-Marietta on May 22, 1970 and authorized the decontamination of the Martin-Marietta, Middle River, Maryland facility. License No. SNM-1192 has the same Docket No. (70-58) as License No. SNM-53 and all records for License No. SNM-1192 are contained in the docket file for License No. SNM-53. Apparently only Building D was decontaminated under License No. SNM-1192. Building D was decontaminated from June to September 1970 and a final survey report provided to the AEC with a letter dated September 22, 1970. The final survey report states that a total of 29 μCi of U-235 remained in five drains which were to

be were sealed with concrete; one small area of fixed Sr-90 contamination (0.5 mrad/hr) also remained. The building was demolished after the survey, leaving only the concrete pad. Region I staff reviewed the available documentation in 1982 and concluded in Combined Inspection Report Nos. 40-3296/82-01 and 40-2308/82-01 that the site met NRC criteria for unrestricted use.

An NRC site visit and survey was performed on November 3, 1994 to assure that the site meets current NRC guidelines for release for unrestricted use. Buildings C and D at the Middle River facility and Buildings KJ and KC at the Martin State Airport were surveyed. The results of the surveys indicate no radiation or contamination levels above background in any of the buildings surveyed, including the concrete pad remaining from Building D. The contaminated drains discussed in the final survey report regarding Building D were not located, although a number of openings in the pad which had been filled with concrete were identified. Therefore, it seems apparent that the drains identified as contaminated during the final survey were plugged with concrete, as proposed by the licensee. Based on the fact that no radiation or contamination levels above background were detected, it seems unlikely that U-235 contamination in the drains, if present, is a significant hazard. Therefore, the site is suitable for unrestricted use.

NRC Reviewer:	David F. Limroth, Stephen W. Holmes		

Review Abstract: License No. SNM-00011 authorized research and development work with U-235 in Building D at Middle River, Maryland. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces. The building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on November 3, 1994 indicate that the site is suitable for unrestricted use.

Recommendations: None.

Summary: License No. SNM-00011 authorized the possession and use of 2 kilograms of U-235 in enriched uranium for fuel element research and development to be used in the licensee's Nuclear Materials Laboratory in Building D, Plant I. The licensee's letter dated September 19, 1957 requested that certain special operations in the fabrication of fuel bundles be permitted in the pilot manufacturing facility and in other buildings at Plant I. The licensee specified that only fully clad uranium fuel tubes or plates would be used in these other buildings. The license expired on May 31, 1961 and was not renewed. On April 7, 1961, the licensee ceritifed that all material possessed under the license had been disposed of prior to expiration of the license.

Information from various docket files indicates that a variety of activities with large amounts of byproduct, source, and special nuclear material were authorized at Building D at the Middle River facility. Activities with licensed material at Building D ceased prior to 1970. License No. SNM-1192 was issued to Martin-Marietta on May 22, 1970 and authorized the decontamination of the Martin-Marietta, Middle River, Maryland facility. License No. SNM-1192 has the same Docket No. (70-58) as License No. SNM-53 and all records for License No. SNM-1192 are contained in the docket file for License No. SNM-53. Apparently only Building D was decontaminated under License No. SNM-1192. Building D was decontaminated from June to September 1970 and a final survey report provided to the AEC with a letter dated September 22, 1970. The final survey report states that a total of 29 μCi of U-235 remained in five drains which were to be were sealed with concrete; one small

area of fixed Sr-90 contamination (0.5 mrad/hr) also remained. The building was demolished after the survey, leaving only the concrete pad. Region I staff reviewed the available documentation in 1982 and concluded in Combined Inspection Report Nos. 40-3296/82-01 and 40-2308/82-01 that the site met NRC criteria for unrestricted use.

An NRC site visit and survey was performed on November 3, 1994 to assure that the site meets current NRC guidelines for release for unrestricted use. Buildings C and D at the Middle River facility and Buildings KJ and KC at the Martin State Airport were surveyed. The results of the surveys indicate no radiation or contamination levels above background in any of the buildings surveyed, including the concrete pad remaining from Building D. The contaminated drains discussed in the final survey report regarding Building D were not located, although a number of openings in the pad which had been filled with concrete were identified. Therefore, it seems apparent that the drains identified as contaminated during the final survey were plugged with concrete, as proposed by the licensee. Based on the fact that no radiation or contamination levels above background were detected, it seems unlikely that U-235 contamination in the drains, if present, is a significant hazard. Therefore, the site is suitable for unrestricted use.

Review Abstract: License No. SNM-00053 authorized the possession of special nuclear material in Building D at Middle River, Maryland and at Timonium, Maryland. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces. The building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on November 3, 1994 indicate that the site is suitable for unrestricted use.

Licensee, NRC, and Maryland State surveys indicate that the Timonium site is suitable for unrestricted use.

Recommendations: NONE

Summary: License No. SNM-00053 authorized possession and use of up to 1,000 kilograms of uranium enriched in U-235 as UO_2 and metal and 160 grams of plutonium in the form of a plutonium-beryllium source. Licensed activities included fuel element development and fabrication at the Middle River facility. On September 23, 1969 License No. SNM-01150 was issued pursuant to an amendment to License No. SNM-00053 to permit the transfer and use of up to 100 grams of U-235, at any enrichment and in any chemical form, for research and development activity, and 171 grams of Pu-235 for neutron and alpha instrument calibration sources, from the Middle River facility to the Timonium facility. Concurrently, SNM-00053 was amended in its entirety to authorize the storage of U-235 in the form of contamination in Building D at Middle River. License No. SNM-00053 (Teledyne-Isotopes) was terminated May 26, 1970. There is no termination or confirmatory survey for License No. SNM-01150.

March 10, 1995

Information from various docket files indicates that a variety of activities with large amounts of byproduct, source, and special nuclear material were authorized at Building D at the Middle River facility. Activities with licensed material at Building D ceased prior to 1970. License No. SNM-1192 was issued to Martin-Marietta on May 22, 1970 and authorized the decontamination of the Martin-Marietta, Middle River, Maryland facility. License No. SNM-1192 has the same Docket No. (70-58) as License No. SNM-53 and all records for License Nos. SNM-1192 and SNM-01150 are contained in the docket file for License No. SNM-53. Apparently only Building D was decontaminated under License No. SNM-1192. Building D was decontaminated from June to September 1970 and a final survey report provided to the AEC with a letter dated September 22, 1970. The final survey report states that a total of 29 μCi of U-235 remained in five drains which were to be were sealed with concrete; one small area of fixed Sr-90 contamination (0.5 mrad/hr) also remained. The building was demolished after the survey, leaving only the concrete pad. Region I staff reviewed the available documentation in 1982 and concluded in Combined Inspection Report Nos. 40-3296/82-01 and 40-2308/82-01 that the site met NRC criteria for unrestricted use.

An NRC site visit and survey was performed on November 3, 1994 to assure that the site meets current NRC guidelines for release for unrestricted use. Buildings C and D at the Middle River facility and Buildings KJ and KC at the Martin State Airport were surveyed. The results of the surveys indicate no radiation or contamination levels above background in any of the buildings surveyed, including the concrete pad remaining from Building D. Therefore, it seems apparent that the drains identified as contaminated during the final survey were plugged with concrete, as proposed by the licensee. Based on the fact that no radiation or contamination levels above background were detected, it seems unlikely that U-235 contamination in the drains, if present, is a significant hazard. Therefore, the site is suitable for unrestricted use.

Licensee letter dated March 25, 1975 documents a survey of the Timonium site consisting of 67 wipes and a portable instrument alpha/beta/gamma survey of "all areas that had been subject to use of radioactive materials" which identified no residual contamination. An NRC letter dated April 15, 1975 of an inspection to confirm disposition of license material under License No. SNM-0849 and an examination of the licensees contamination survey reported that "no items of noncompliance were observed". The State of Maryland terminated License MD-05-014-01 (formerly USNRC License No. 19-01398-34) covering the whole site after performing a confirmatory survey on July 19, 1993 of the licensee's termination survey of June 8 and 9, 1993. The site is suitable for unrestricted use.

Summary

The close-out survey showed that the operational area defined in the licensee's report, "Comprehensive Radiation Survey Report for the Release of Decontaminated Premises for Unrestricted Use", (see copy enclosed as Exhibit A), had been decontaminated below the level defined in that publication, in the section entitled, "USAEC Radioactivity Contamination Limits for Abandonment of Facilities and Equipment". In December, 1970, Walter R. Lorenz informed R. T. Woolsey, [redacted], of his survey findings.

History

The facility at Middle River, Maryland, was formerly licensed for use with special nuclear materials, source materials, and byproduct materials. Source and special nuclear materials were converted from the oxides to ceramic pellets and then loaded into fuel bundles. R&D was also performed in support of the fuel processing. Byproduct material was used on an R&D basis and SNAP generators were assembled at the facility. The facility was licensed for greater than ten years.

Exhibit "A"

Exhibit "A" contains a summary of the health physics coverage given personnel and the resultant exposure personnel received during the decontamination work. From the results reported, it appears that no persons were overexposed, in fact, it appears that personnel received only minimal exposure both internally and externally.

Exhibit "A" gives only minimal data as to meeting the deminimus criteria for abandonment of a facility as set out in Section V, Page 11 of their safety procedures (an enclosure to Exhibit "A"), which are referenced by License Condition 9. To supplement this, the inspector obtained a more detailed record of the licensee's survey results confirming that the AEC deminimus criteria had been achieved. This data is included as Exhibit "B" of this report.

Observations During Inspection

An inspection of this multiroom facility in the basement of a huge airport hanger was made. It was observed that the rooms were almost completely stripped of all operational equipment. Ducts, false ceilings, all

equipment, ducts, etc., were removed, packaged, loaded onto Nuclear Engineering Inc., trucks and shipped for burial. The inspector, having prior knowledge of the facility, paid specific attention to areas that were known to have been contaminated. The radiography room, where the wall was contaminated with Sr-90, was noted to have been decontaminated by use of a jack hammer. No contamination was evident in the radiography room, per the inspector's survey, both by smearing and direct surveying with an end-window GM survey meter. The UO_2 powder handling room was observed to have been completely gutted, including electrical switches, false ceiling and two of the four walls which had been completely removed. Floor tiling had been removed in the chemistry labs where known floor contamination had existed.

Inspector's Survey Results

Approximately 50 smears at various locations were taken by the inspector using Whatman No. 42 filter paper. These smears were taken on floors, walls, fixtures, drains, etc., where, in the inspector's opinion, contamination, if present, would most likely be found. These smears were counted at HASL using an alpha scintillation counting system, having a 37% efficiency for Pu-239, and a low background beta scintillation counting system, having a 25% efficiency for Sr-90. The maximum alpha activity detected was 270 d/m/100 cm^2 and the majority of the smears showed less than 10 d/m/100 cm^2. The maximum beta activity detected was 40 d/m/100 cm^2.

Direct surveys were made in the various areas using an Eberline PAC-1SA (50% efficient and 69 cm^2 area) and an Eberline E-120 end-window beta-gamma survey meter having a window thickness of 1.2 mg/cm^2. Direct alpha surveys were made in all rooms and areas where material was handled. The maximum result noted was found in the inlet side of an absolute filter bank plenum; 6000 d/m. Only the duct and framing remained. All else had been removed for burial, including the blower. Other maximum alpha survey results in other rooms and areas were at 2000 d/m and 3000 d/m. The average fixed alpha radiation levels were less than 500 d/m.

The maximum beta-gamma radiation level noted by the inspector was .4 mrad/hr. This level was also found on the inlet side of the absolute filter bank framing. All other levels noted were less than 0.1 mrad/hr, including the wall where Sr-90 fixed contamination was known to have been embedded.

I. INTRODUCTION

Purpose: This radiation survey report is prepared as one of the conditions provided for in U.S.A.E.C. Material License No. SNM-1192 issued to the Martin Marietta Corporation for the decontamination of nuclear laboratories at Baltimore, Maryland.

Since the subject nuclear laboratories are no longer used for radioisotopes operations and/or special nuclear materials processes and have been decontaminated in accordance with U.S.A.E.C. guidelines, it is requested the above named facilities be released for unrestricted use.

On June 3, 1970, the decontamination program at the Martin Marietta Corporation, Baltimore Division, commenced and it was completed on September 2, 1970. The radioactive materials involved in the decontamination program consisted primarily of U^{235} and U^{238} in a residual oxide form.

The work was performed by a crew consisting of 8 trained operators from the Martin Marietta Corporation, two health physicists from Eberline Instrument Corporation, and one health physicist from Martin Marietta Corporation. The removal of the radioactive material from equipment and facilities was achieved primarily through the use of high vacuum systems, with the operators wearing U.S. Bureau of Mines air supplied respirators. Full protective clothing and footwear were provided the workers.

Air samples were collected throughout the general area during the decontamination program and were counted for gross alpha emitters. The results of all air samples collected were below the MPC, with the exception of 4 samples. One sample was collected in the Radioisotopes Laboratory while chipping SR^{90} from a concrete wall. The result was reported as 2.4×10^{-10} uCi/CC. The second sample was collected in the Spheroidizing Room while removing ventilation ducts. The results of the air samples are given in Appendix C-1.

It should be noted that air supply respirators were worn by the operators during the time the air dust concentrations were measured. Urine specimens were submitted by personnel assigned to the program prior to working in the contaminated areas, in order to provide a base line study. Nasal swipes of all men working in the contaminated areas were performed twice daily. The results of all nasal swipes were low to negligible and did show proper use of respiratory protective equipment.

Water samples were collected of all liquid effluent, analyzed prior to release, and records of all sample analysis and personnel dosimetry reports are maintained in the office of the Martin Marietta Corporation's health physicist.

II. LOCATION AND IDENTIFICATION OF FACILITIES

The subject nuclear laboratories that were decontaminated are located at Chesapeake Park and are owned by Martin Marietta Corporation at Baltimore, Maryland. The decontaminated laboratories encompass an area of approximately 40,000 FT^2, located in the basement area of building "D". The total area was subdivided into small separate rooms where various types of nuclear activity were performed. Most of the small rooms were of the laboratory-type, and equipment included ventilation hoods, glove boxes, filtration medias, laboratory benches and laboratory glassware. False ceilings were also a part of some laboratories, and each ceiling was surveyed and removed, where necessary.

For the most part, the radioactivity was confined to glove boxes, ventilation hoods, ducts and filtration medias contained in each laboratory. The radioactive materials removed were in the form of residual uranium oxides, with the exception of a minor amount of SR^{90} found on a wall.

Some of the laboratories contained sinks, floor drains and sumps used to control liquid effluent containing radioactive materials. The floor drains, traps and sumps were carefully monitored to determine the contamination level, if any, and the termination location of each drain line and sump line.

III. HEALTH PHYSICS TECHNICAL APPROACH

The removal of residual contamination was accomplished through the direction and guidance of three health physicists, two from Eberline Instrument Corporation and one from Martin Marietta Corporation. The work crew consisted of eight qualified workers trained in the radiological health aspect of nuclear decontamination.

The contamination, for the most part, was not found to be tightly bonded or sealed to the surfaces of the facilities and therefore most of it was removed by the use of high vacuum systems with absolute filters. One wall and several floor areas showed evidence of bonded alpha activity and, therefore, it became necessary to use pneumatic tools to remove the contamination and reduce radiation levels to acceptable levels. Contamination that was found to be fixed on equipment, such as ventilation hoods, ducts and glove boxes, was allowed to remain fixed, and the equipment was properly packaged, identified and shipped by truck carrier to burial grounds in Moorehead, Kentucky. The transportation and burial of all contaminated equipment was provided by the Nuclear Engineering Company, Moorehead, Kentucky.

IV. SCOPE OF SURVEY AND GENERAL PROCEDURES FOLLOWED

Radiation detection equipment used during the effort included several gas proportional alpha counters, one floor alpha monitor, RM-15 (soft gamma measurement), one beta plus gamma counter, TLD badges and film badge dosimetry.

Swipe samples by the use of whatman filter paper were collected from all surface areas where it was thought to be necessary. The filter paper samples were then counted for any gross alpha contamination. All loose radioactive material was removed from the facilities. Equipment that was heavily contaminated, such as glove boxes and ventilation hoods, were properly packaged and shipped by carrier truck for burial.

There were no areas detected whereby radioactive materials had been sealed by painting or by other means, and there was no attempt to seal any areas containing fixed radioactive materials.

The general procedure followed to accomplish the decontamination effort is entitled "The Health and Safety Procedure for the Decontamination of Building "D", Martin Marietta Corporation, Baltimore, Maryland." The procedure is presently on file in the office of the U.S.A.E.C. Division of Materials Licensing. The procedure provided the basic guidelines for performing the decontamination in a safe manner. "The Guidelines for Decontamination of Facilities and Equipment Prior to Release for Unrestricted Use" was closely adhered to by the Martin Marietta Corporation decontamination work crew.

V. FINDINGS OF THE DECONTAMINATION SURVEY

The floors, walls and ceilings of all laboratories where nuclear activity was conducted were monitored and recleaned. Some areas did not show evidence of contamination. Those areas where contamination was found were vacuumed and sprayed with a jet-x cleaning device to remove any material that could not be vacuumed. The use of water was controlled and kept to a minimum to prevent water contamination and pollution.

During the initial phase of the decontamination inspection survey, six items or areas were found which required correction (letter to E. M. Chenault from S. J. Waligora, Jr., dated September 3, 1970) and all, with the exception of the floor drains, were corrected.

All floor drains were monitored and decontaminated as much as possible. Water samples were taken from the five drains indicating residual activity and all results showed low concentrations. (See Appendix C-2) The residual activity remaining in the six drains was estimated through the use of a 2" x 2" NaI(TR) crystal in conjunction with a single channel analyzer. With the detection system calibrated for ^{235}U gamma rays, the following estimates were established:

Drain No.	^{235}U(uCi)
39	1.0
46	1.0
52	15.0
55	6.0
56	6.0
Total	29.0

Water samples taken from these drains showed very low concentrations. As a further check, water was flushed continuously through these five drains while a two liter water sample was taken from the sanitary sewer sump servicing that portion of the building. Samples were submitted for analysis and showed 0.003 pCi/ml (MPC 30.0 pCi/ml).

All drains have been left open for inspection. With approval from the U.S. Atomic Energy Commission, we propose to seal the five drains with cement, thereby permanently inactivating the total of 29 uCi of ^{235}U. This measure would appear to be a feasible alternative to tearing out the concrete floor in order to remove the drains and associated pipe.

As a result of the final survey, all other areas were reduced to within limits prescribed by the U.S. Atomic Energy Commission. All walls, ceilings, and floors had been washed thoroughly or removed. The average alpha emitter contamination (^{235}U and/or ^{238}U only) is much less than 500 dpm/100 cm^2. Areas with remaining fixed alpha emitter contamination average less than 2,000 dpm/100 cm^2. Beta-gamma contamination is essentially nonexistent; ^{90}Sr-Y contamination which had been present in the Radioisotopes Laboratory has been completely removed with the exception of one minute area with fixed contamination measuring 0.5 mRad/hr.

This area of Building "D" will soon be renovated by Chesapeake Park and any remaining fixed contamination will be further enclosed with replastering, retiling of floors, and repainting. Following the renovation, any fixed residual contamination should be so well fixed that there should be no evidence of even trace quantities during the remaining life of the structure.

VI. PACKAGING, TRANSPORTATION AND DISPOSAL OF CONTAMINATED EQUIPMENT

All contaminated equipment, such as glove boxes, ventilation hoods and duct work, were properly packaged and identified in accordance with the Department of Transportation rules and regulations and sent by truck carrier to Moorehead, Kentucky, for burial. A total of nineteen (19) truckloads of equipment were sent to the burial grounds, with each truckload encompassing approximately 1,920 cubic feet.

APPENDIX B - SUMMARY OF DECONTAMINATION OPERATIONS

The following is a chronological task summary of decontamination operations from June 1 through September 3, 1970, and represents approximately 2400 man hours of labor.

1. Organization of people, equipment, supplies, and facilities; establishment of procedures and policies.
2. Removal of exhaust ducts from furnace room.
3. Samples taken from areas with potential for tritium and for cobalt 60 contamination.
4. Machinery and equipment removed from furnace room.
5. Areas expected to be clean were monitored and any anomalies entered to the work plan.
6. Arrangements were made for special disposal of nonradioactive but hazardous wastes (acids, alkalis, solvents, nitrates, peroxides, etc.)
7. Removed parafin shielding from neutron generator area.
8. Removed equipment from laundry area.
9. Surveyed dehydrator rooms and segregated areas and equipment.
10. Cleaned nine rooms which required general decontamination, but which posed no problems due to presence of contaminated equipment, exhaust ducts, absolute filters, etc.
11. Laundry area cleaned including removal of construction blocks and floor tiles.
12. Cleaned powder room - highly contaminated.
13. Discovered "contamination" in heat plant boiler room which analyses showed to be naturally occurring thorium.
14. Fire (primarily smoke) as the result of torches used during duct removal on outside of building by a local contractor. This duct work was past the absolute filter bands and there was no attendant

15. General cleaning accomplished in five additional rooms.

16. Vault decontaminated and bird cages removed.

17. Chipped concrete walls contaminated with ^{90}Sr-Y in Radioisotopes Laboratory.

18. Ductwork removal and clean-up in two additional rooms.

19. Removed glove boxes and other contaminated equipment from Spheroidizing Room; proceeded with remainder of clean-up.

20. Removed installed casework in Inorganic Chemistry Laboratory.

21. Decontaminated restroom floors in supposedly clean area.

22. Cleaned contamination which resulted from clean-up of Spheroidization Room.

23. Inspected Oil Farm Building (remote to Building "D") and removed contaminated equipment that had been stored. Survey showed no further decontamination was necessary.

24. Proceeded with clean-up of Inorganic Chemistry Laboratory.

25. Removed ducts and proceeded with clean-up of Powder Metal Room.

26. Removed duct and proceeding with clean-up of three rooms.

27. Removed duct work and equipment in Ceramics Laboratory and Spheroidization Laboratory.

28. Steamed Pellet Room in preparation to clean-up in order to reduce airborne (resuspended) contamination. Proceeded with clean-up.

29. Powder Room was also steamed prior to clean-up.

30. Removed absolute filters associated with Pellet Room.

31. All drains monitored and cleaned. Five remain contaminated.

32. Removed vertical rolling mill (several tons) from Powder Room. Residual contamination forced removal of two walls, ceilings, and floor tiles.

33. Ceiling and floor tiles removed in Spheroidization Room.

34. Removed absolute filters associated with Vault Room.

35. Final blowers, filters and ducts removed at termination and ventilation exhaust equipment.

36. Removed absolute filters and remainder of equipment associated with the Radioisotopes Laboratory.

37. Proceeded throughout entire facility with final monitoring and removed any contaminated items including floor tile, miscellaneous fixtures. Washed down all remaining ceilings, walls, and floors several times. A detailed swipe survey was performed.

38. Sumps and chip tanks associated with Dehydrator, Laundry Room, and Cleaning Room were decontaminated.

39. Asphalt floor covering in Cleaning Room removed.

40. Final waste shipment (19th truckload) departed. Two additional barrels filled with remaining miscellany for future shipment.

APPENDIX C - SAMPLE ANALYSIS RESULTS

1. Environmental Air Samples

Location	Date	Concentration (uCi/ec)
Radioisotopes Laboratory	7/9/70	$92.3 \pm 0.6 \times 10^{-12}$
Radioisotopes Laboratory	7/9/70	$240.0 \pm 1.0 \times 10^{-12}$

I. Introduction

The Martin Marietta Corporation, Denver Division, has demonstrated a history of successful and safe programs utilizing radioactive materials and is presently licensed to handle and process radioactive materials. The health and safety plan described in this volume utilizes the experience and knowledge developed in past programs to guarantee compliance with the health and safety requirements of this program.

This health and safety plan has been prepared by a Health Physicist and Industrial Hygiene Engineer of the Martin Marietta Corporation, Denver Division, and in consultation with U. S. A. E. C. representatives and State Health Department radiological officials. The plan has been reviewed by a certified health physicist.

The place where the decontamination operations will occur is located in the lower level of building "D" designated as the Nuclear Facilities. The area encompasses approximately 40,000 square feet and consists of concrete floors covered with linoleum tile, acoustical false ceiling tile, and wall partitions with painted smooth surfaces. Most of the area has been subdivided into small laboratories that consist of very little equipment, but a considerable number of ventilation hoods, ducts, and a few glove boxes.

The period of time for which the license is requested is six (6) months; however, it is noted that the decontamination activity is planned to require approximately 9 - 10 weeks to complete. The additional time is requested primarily to ensure that adequate time is applied to the license to avoid expiration of license before the job is completed.

The type of special nuclear materials to be removed from equipment and facilities is residual amounts of uranium oxides enriched in isotopes U^{235}. The quantity of U^{235} is small and does not create a criticality hazard. This has been verified with portable scintillation gamma detectors. Most of the uranium is contained in glove boxes and ventillation hoods which will be disassembled, properly packaged, and shipped to an approved waste disposal site. The walls, floors, and permanent fixtures are relatively free of radioactive contamination.

II. Purpose

This procedure has been prepared for submittal to the U. S. Atomic Energy Commission as part of an application for licenses to decontaminate the Nuclear Engineering Laboratories, Building "D", Chesapeake Park, Inc., Baltimore, Maryland.

The attached procedure has been prepared in accordance with the U. S. Atomic Energy Commission Rules and Regulations, Title 10, Parts 70 and 20.

III. The Health Physics and Industrial Hygiene Engineering Technical Approach

The process of decontaminating the nuclear facilities and equipment presents certain health hazards and contamination problems from primarily radioactive dust (U^{238} and U^{235}) and a minor external radiation hazard.

The potential dust sources that present personnel inhalation hazards are:

1. The removal of residual uranium oxides from equipment and facilities,
2. The removal of equipment, filters, ducts, collection systems, etc.,
3. Accidental spills of residual powder,
4. Packaging of dust-laden equipment for burial,
5. Handling of contaminated equipment, and
6. Waste disposal.

Three health physicists and a radiation monitor will provide the necessary radiological health guidance.

The Eberline Instrument Corporation (EIC), Santa Fe, New Mexico, shall provide a certified health physicist to prepare work order packages for each phase of the decontamination. A qualified health physicist and one monitor shall be provided by EIC during the decontamination and packaging of waste to insure adequate health and safety protection of people performing the task, to control contamination, and to insure compliance with the Department of Transportation and U. S. A. E. C. rules and regulations. EIC shall also provide analytical services for radiation dosimetry, air, water, soil, and bioassay samples. EIC shall provide a certified health

physicist for the final survey to certify that the facility meets the criteria for abandonment in Part V of these procedures.

The Martin Marietta Corporation shall provide a qualified health physicist and a trained and experienced work crew consisting of approximately eight (8) men and one supervisor to decontaminate the facilities, equipment, and package contaminated equipment for shipment to approved burial grounds. The work crew assigned to decontaminate the nuclear facilities have had experience working with hazardous materials and have received radiological health indoctrination courses.

The decontamination process shall be systematically conducted and well organized. Each room will be decontaminated by keeping dust generation and liquids use to a minimum according to a work order package prepared for that room. After the room has been decontaminated, it will be surveyed to determine that the level of residual contamination is below the limits in Part V. The room will then be locked and marked as being clean. The entire program will be well planned to achieve maximum performance without incident.

A. Respiratory Equipment

No employee will be permitted to perform work where airborne radioactivity exceeds concentration guides for U^{235}. If operations must be performed for short periods of time in a radioactive dust-laden atmosphere, respiratory protective devices and protective clothing will be used. The respirators will be of the air line or backpack type. Sufficient numbers of these are available. However,

respirators are no substitute for engineering control; therefore, exposure to any level of radioactive dust concentration will be kept to an absolute minumum by engineering means.

B. Protective Clothing

In facilities where contamination is present, personnel will change into anti-contamination clothing that is not removed from the area. Such clothing will be packaged, tagged, identified, and sent out to a special laundry or disposed of as radioactive waste. Such laundry facilities will be approved by local, state, and federal authorities (U.S.A.E.C.) prior to use.

C. Equipment Contaminated

Radioactive powder will be removed from equipment by vacuum or by wiping with a moist cloth prior to being removed from its original location. Protective clothing will be worn by personnel. Respiratory protection will be provided during periods when occupational concentration guides may be exceeded temporarily. Radioactive contaminated rags, paper, clothing, etc., will be deposited in properly identified containers for disposal or cleaning as directed by the Health Physicist.

IV. Specifications for the Decontamination of Fixtures, Facilities and Equipment Contaminated by Radioactive Materials.

The decontamination of all facilities and equipment must be in an orderly, planned fashion and shall not create a health hazard to personnel. Precautions shall be taken to prevent the spread of contamination to sanitary or storm sewer lines and pipes.

A change room will be provided for changing from street clothes into protective (anti-contamination) clothing to prevent spread of contamination to clean area.

Actual work areas shall be posted with signs indicating radiation work in progress, only authorized personnel allowed entry. Temporary barriers will be set up to keep those not working directly with the material at a safe distance.

Coveralls and gloves are required to be worn by all personnel entering contaminated area.

The maintenance of radiation exposure records on each employee engaged in the decontamination operation shall be the responsibility of the Martin Marietta Corporation along with the provision of protective clothing and equipment.

All chemical liquids, equipment, and detergents shall be provided by Martin Marietta.

All equipment, fixtures, and facilities decontaminated must be approved in writing by the U. S. Atomic Energy Commission before said equipment, fixtures, and facilities are accepted by Chesapeake Park, Inc.

All equipment, fixtures, and facilities which have been cleaned and meet the U. S. Atomic Energy Commission decontamination level for safe disposal must be marked or tagged.

Martin Marietta Corporation Health Physicist shall have access to all areas prior to decontamination, during decontamination, and after decontamination. He shall be afforded the opportunity to converse and make recommendations to the EIC health physicist, and monitor any or all equipment and facilities. He shall function as liaison with Martin Marietta Corporation Contractor and Chesapeake Park, Inc.

Emergency Procedure - Fire: Fires involving enriched uranium must be extinguished with a metal-x powder extinguisher. Fire extinguishers, metal-x powder type and dry powder, must be provided by Martin Marietta and available for use during decontamination operation.

The Martin Marietta Corporation crew must decontaminate all equipment, facilities, fixtures, and other equipment to radiation levels acceptable to the U. S. Atomic Energy Commission.

The safe disposal of all radioisotope waste and contaminated equipment and fixtures shall be the responsibility of Martin Marietta, consistent with U. S. Atomic Energy Commission and Department of Transportation regulations.

During decontamination operation, Martin Marietta Corporation crew must ensure that dust, fumes, smoke, vapor, or mist are not generated to create a health hazard to any personnel or to contaminate equipment or facilities.

A decontamination room, designated by Chesapeake Park, Inc., and accepted by the Martin Marietta Corporation Health Physicist, shall be utilized for decontamination of various types of equipment.

The Health Physicist must ensure that personnel returning from the contaminated area observe established control procedures to prevent spreading contamination to clean work areas, eating spaces, offices, and other areas. Each must be monitored as soon as he exits from the contaminated area. Used protective clothing must be placed in proper containers.

V. U. S. A. E. C. Radioactivity Contamination Limits for Abandonment of Facilities and Equipment.

All facilities and equipment contaminated by radioactive materials shall be decontaminated to those limits prescribed by the U. S. A. E. C. and are as follows:

1. The maximum amount of fixed alpha radioactivity in disintegrations per minute per 100 square centimeters on buildings or equipment shall not exceed 25,000.
2. The average amount of fixed alpha radioactivity in disintegrations per minute per 100 square centimeters on buildings or equipment shall not exceed 5,000.
3. The maximum amount of removable (capable of being removed by wiping the surface with a filter paper or soft absorbent paper) alpha radioactivity in disintegrations per minute per 100 square centimeters on buildings or equipment shall not exceed 1,000.
4. The maximum level at one centimeter from the most highly contaminated surface of a building or piece of equipment measured with an open window beta-gamma survey meter through a tissue equivalent absorber of not more than seven milligrams per square centimeter shall not exceed one millirad per hour.

VI. Air Sampling Program for Radioactive Dust Surveys

A. Sampling Instruments

The following photographs (Fig. 1 thru 3) show the type of air dust sampling equipment that will be used to monitor the area for uranium oxides that may present an inhalation hazard to personnel. The instrumentation is suitable for monitoring the environment in-plant as well as out-plant for airborne radioactive dust.

Figure 1 - Shows the air sampler and filter holder that will be used to collect air dust samples at the breathing zone of workers who may be exposed to radioactive dust.

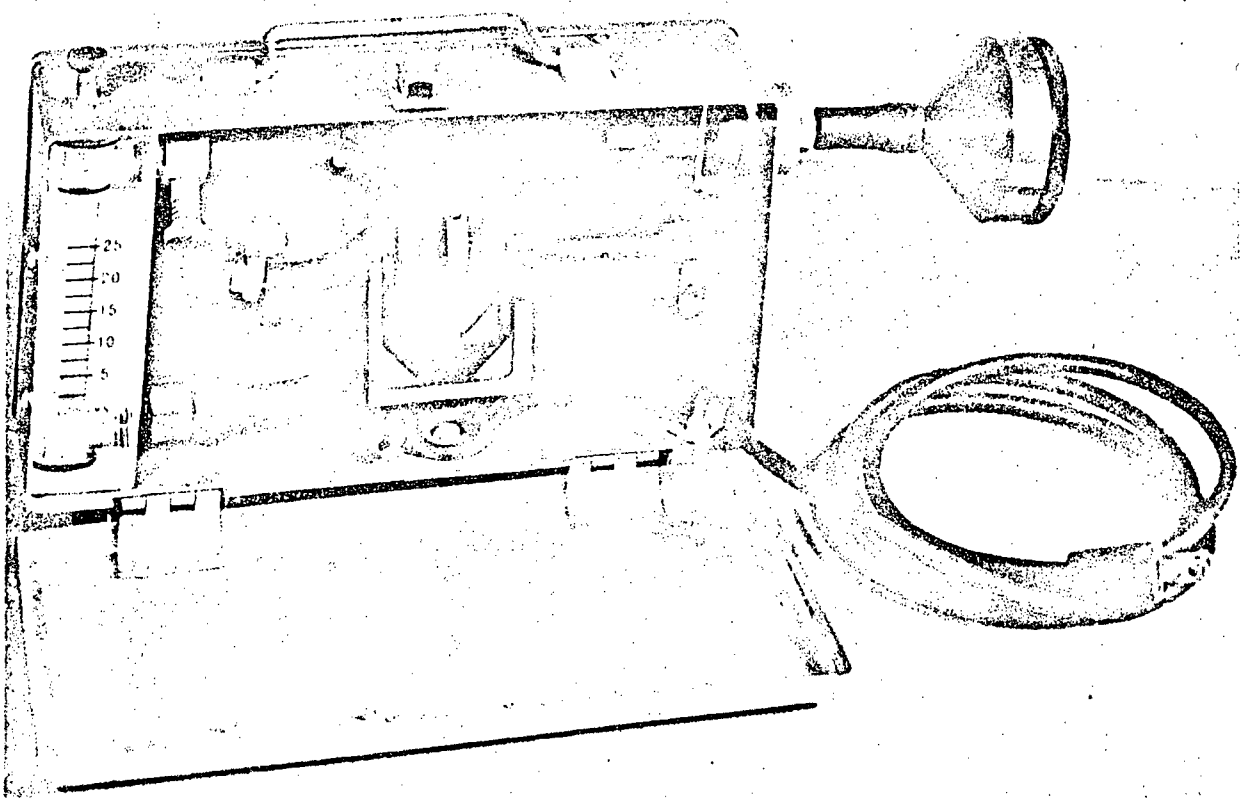

Figure 1

Figure 2 - Shows a combination of air dust samplers equipped with filters that may be used for out-plant sampling as well as in-plant dust sampling.

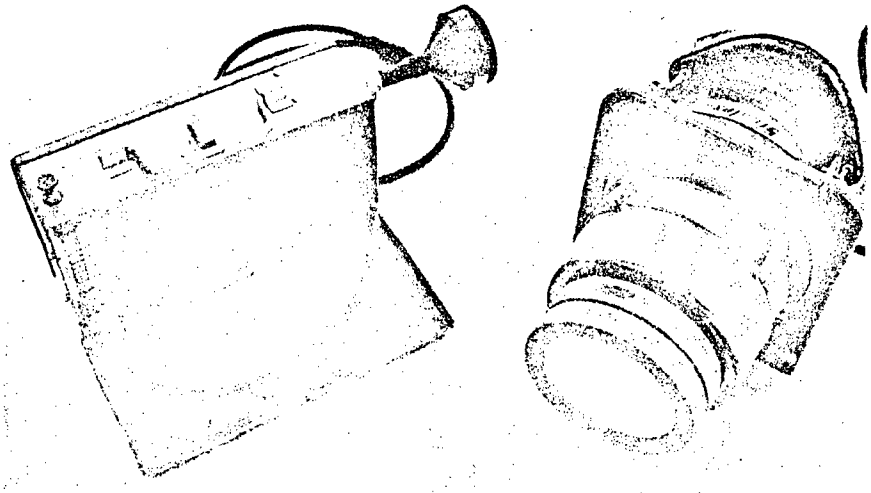

Figure 2

Figure 3 - Shows the high volume sampler capable of pulling 70 cfm of air for dust sampling and can be used for in-plant as well as out-plant dust sampling for radioactive matter.

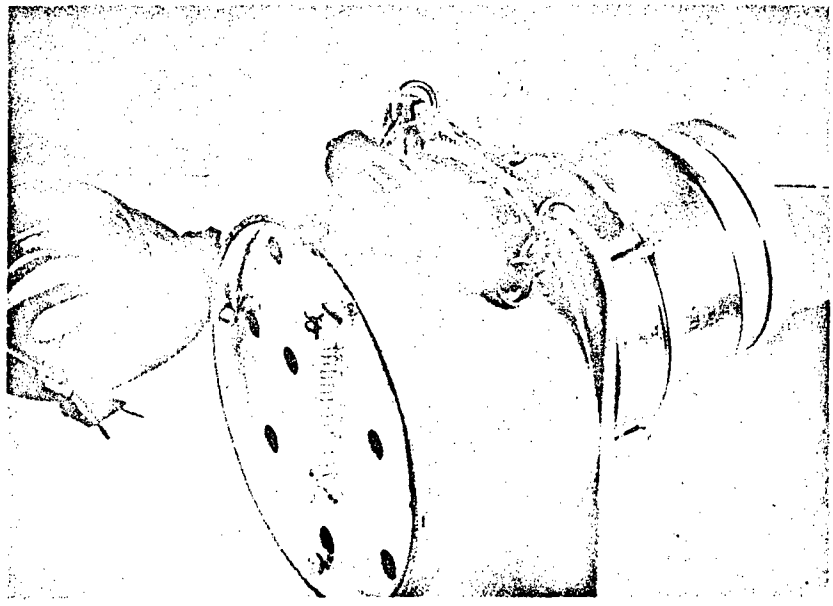

Figure 3

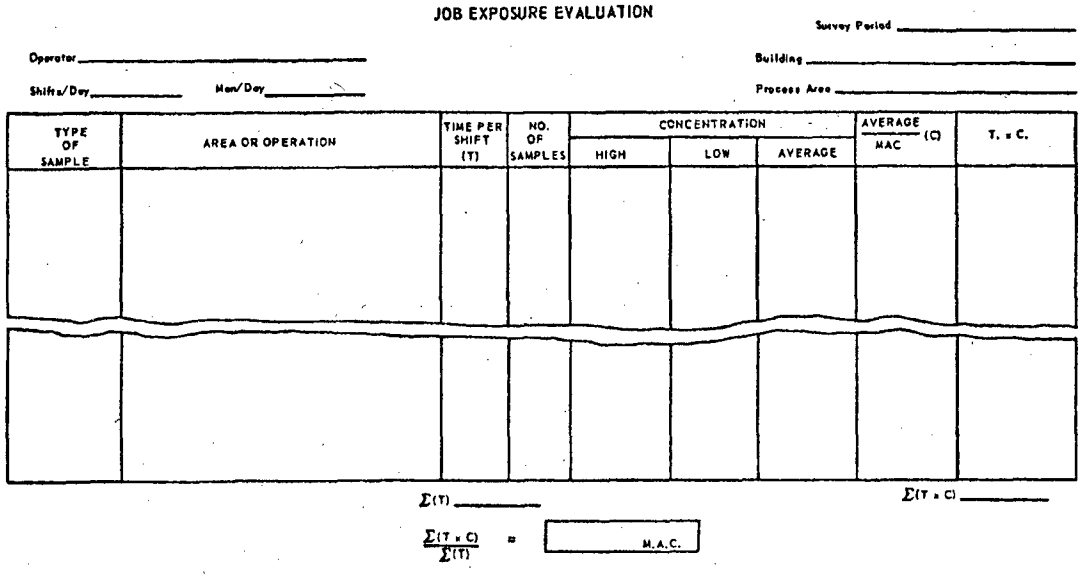
B. Job Exposure Evaluation Data Sheet

The job exposure evaluation data sheets (Fig. 4) will be used to determine the daily weighted exposure of operators involved in the decontamination program. The dust sample results (breathing zone and general area) will be compiled and recorded on the data sheets for daily weighted exposure calculation. Specific job operations will be included on these data sheets.



JOB EXPOSURE EVALUATION

Survey Period _____

Operator _____ Building _____

Shift#/Day _____ Man/Day _____ Process Area _____

D. Industrial Hygiene Analytical Data Sheet

The following analytical data sheet (Fig. 6) will be used to collect air, water and soil samples. A complete description of the samples collected will be written on the data sheet and accompany the samples to the laboratory for analysis. The result of the samples will be recorded on the data sheet and filed after review by the health physicist.

VIII. Contamination Control

A. Air

Airborne activity will be kept to a minimum through the use of vacuum machines and damp cloths to remove loose uranium oxides. There shall be no brooms or air hoses used to decontaminate equipment or fixtures containing uranium oxides. Air supply respirators shall be worn by personnel when involved in dust generating activity.

B. Water

There shall be no release of liquid effluent into domestic sewers or storm sewers until water samples have been taken to determine the quality of the effluent and to ensure there is no contamination present, radioactive or chemical.

C. Soil

Soil samples shall be taken whenever it is thought or determined that contamination to the ground has occurred.

D. Personnel

All personnel involved in the decontamination process shall be provided and shall wear full protective clothing and approved respiratory equipment. Showering once per day prior to leaving the facilities is mandatory. There shall be no smoking or eating inside areas designated as contaminated. There shall be access control to the work areas and only those people assigned shall be permitted entry.

IX. Personnel Orientation and Bioassay

A. Personnel Orientation

All personnel assigned to the decontamination program will receive a health and safety lecture regarding radiological health as it relates to the decontamination program.

B. Bioassay

The EIC will provide the bioassay analysis for all bioassay samples regarding uranium. A sample will be collected from each worker prior to start of clean-up activities and at the conclusion of decontamination. Samples in between start and completion may be taken, depending on circumstances.

X. Waste Disposal

The Nuclear Engineering Company, Walnut Creek, California, with burial grounds for radioactive waste in Moorehead, Kentucky, will be chosen as the carrier and receiver of contaminated equipment and radioactive (uranium) waste.

The packaging and shipping of radioactive waste and contaminated equipment shall be in compliance with the Department of Transportation and the U. S. Atomic Energy Commission rules and regulations governing packaging, shipping, and burial.

XI. Resume and Experience of Personnel

A. E. M. Chenault, Health Physicist, Martin Marietta Corporation

E. M. Chenault has sixteen years of experience and training in the fields of health physics and industrial hygiene. He is employed by Martin Marietta Corporation as a health physicist and is responsible for the control of radiological health, industrial hygiene, air and water pollution control. He shall be in charge of the decontamination program for the Chesapeake Park, Inc., facilities. He has held a "Q" clearance with the U. S. Atomic Energy Commission when he worked as a health physicist and industrial hygiene engineer for the National Lead Company of Ohio, which is a prime contractor for the U. S. A. E. C. The National Lead Company is a uranium mill processing plant located in Cincinnati, Ohio.

E. M. Chenault is a graduate of the Far East Chemical College and a former U. S. Army instructor in Chemical, Biological and Radiological Warfare. He holds an associate degree and a bachelor degree in physical sciences and completed advanced study in nuclear radiation, radiological health and instrumentation, and industrial engineering ventilation at Michigan State University. He is an appointee of the Governor of Colorado to the State Air Pollution Control Board and a member of the Colorado State Health Department Ad Hoc Committee on Occupational Health. He has been approved by the Colorado State Department of Public Health, which is an agreement state and the U. S. A. E. C. to serve as a radiation protection officer on nuclear material license. He has written

numerous papers on the subject of radiation and the health aspect of beryllium processing.

STATE OF COLORADO

DEPARTMENT OF PUBLIC HEALTH

RADIOACTIVE MATERIALS LICENSE

Pursuant to the Radiation Control Act Chapter 66, Article 26 CRS 1963, as amended, and the Radiation Control Regulations Part III, and in reliance on statements and representations heretofore made by the licensee designated below, a license is hereby issued authorizing such licensee to transfer, receive, possess and use the radioactive material(s) designated below; and to use such radioactive materials for the purpose(s) and at the place(s) designated below. This license is subject to all applicable rules, regulations, and orders now or hereafter in effect of the State Department of Public Health and to any conditions specified below.

Licensee	3. License number
1. Name Martin Marietta Corporation	Colo. 12 - 11 S
2. Address P. O. Box 179 Denver, Colorado 80201	4. Expiration date February 28, 1973
	5. Reference number (U.S. A.E.C. - SMB-112)

6. Radioactive materials (element and mass number)	7. Chemical and/or physical form	8. Maximum quantity licensee may possess at any one time
A. Thorium	A. Thorium-magnesium alloy not more than 4% thorium by weight	A. 700 pounds total alloy

CONDITIONS

9. Authorized use. (Unless otherwise specified, the authorized place of use is the licensee's address stated in Item 2 above.)

A. To be used in accordance with the statements, representations, and procedures contained in application dated January 26, 1970.

10. The radioactive material may only be used at the licensee's Waterton, Colorado facility.

11. The licensee shall comply with the provisions of Part IV, State of Colorado Rules and Regulations Pertaining to Radiation Control, "Standards for Protection Against Radiation".

12. Radioactive material shall be used by, or under the supervision of E. MacDonald Chenault.

13. This license does not authorize welding, melting, chemical milling, pickling, grinding or filing of the material held under this license.

Date February 5, 1970

STATE OF COLORADO

DEPARTMENT OF PUBLIC HEALTH

APPLICATION FOR RADIOACTIVE MATERIAL LICENSE

INSTRUCTIONS — Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail two copies to: Colorado State Department of Public Health, Radiation Hygiene Section, 4210 E. 11th Ave., Denver, Colorado 80220. Upon approval of this application, the applicant will receive a State of Colorado Radioactive Material License, issued in accordance with the general requirements contained in the State Department of Public Health, Radiation Control Regulations and the State of Colorado Radiation Control Act, Chapter 66, Article 26 CRS 1963, as amended.

NEW APPLICATION ☐ AMENDMENT TO LICENSE ☐

1. (a) NAME AND STREET ADDRESS OF APPLICANT. (Institution, firm, hospital, person, etc.) Martin Marietta Corporation P. O. Box 179 Denver, Colorado 80201	(b) STREET ADDRESS(ES) AT WHICH RADIOACTIVE MATERIAL WILL BE USED. (If different from 1 (a).) Martin Marietta Corporation P. O. Box 179 Denver, Colorado 80201
2. DEPARTMENT TO USE RADIOACTIVE MATERIAL. Manufacturing	3. PREVIOUS LICENSE NUMBER(S). (If this is an application for renewal of a license, please indicate and give number.) SMB-112-USAEC
4. INDIVIDUAL USER(S). (Name and title of individual(s) who will use or directly supervise use of radioactive materials. Give training and experience in Items 8 and 9.) James Orem Tim Renzio Neither of the above individuals have training and experience with radiation.	5. RADIATION PROTECTION OFFICER. (Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9). Elmer M. Chenault Health Physicist (See Attached)
6. (a) RADIOACTIVE MATERIAL. (Elements and mass number of each.) Magnesium - Thorium HM21A-T6l Thorium - 1.5 to 2.5% (4) Pc's 160# ea. Manganese .45 to 1.1%	(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM QUANTITY OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. (If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.) Metal Plate

7. DESCRIBE PURPOSE FOR WHICH RADIOACTIVE MATERIAL WILL BE USED. (If radioactive material is for "human use," Supplement A (FORM AOR-RH-13) must be completed in lieu of this item. If radioactive material is in the form of sealed sources, include the make and model number of the storage container and/or device in which the source will be stored and/or used.) Attach extra sheets if necessary.

Missile and Spacecraft Structure.

TRAINING AND EXPERIENCE OF EACH INDIVIDUAL NAMED IN ITEM 4 (Use supplemental sheets if necessary).

8. TYPE OF TRAINING E. M. CHENAULT	WHERE TRAINED	DURATION OF TRAINING	ON THE JOB (Circle answer)	FORMAL COURSE (Circle answer)
a. Principles and practices of radiation protection	Far East Chemical College Gitu, Japan	1 Yr.	Yes No	Yes No
b. Radioactivity measurement standardization and monitoring techniques and instruments	National Lead Co. of Ohio U.S.A.E.C. Contractor Cincinnati, Ohio	9 yrs.	Yes No	Yes No
c. Mathematics and calculations basic to the use and measurement of radioactivity	Univ. of Cincinnati Far East Chemical College	6 mo. 1 yr.	Yes No	Yes No
d. Biological effects of radiation	Univ. of Cincinnati Ohio Civil Defense Authority	1 yr. 1 yr.	Yes No	Yes No

9. EXPERIENCE WITH RADIATION (Actual use of radioisotopes or equivalent experience).

ISOTOPE	MAXIMUM AMOUNT	WHERE EXPERIENCE WAS GAINED	DURATION OF EXPERIENCE	TYPE OF USE
U235	Classified	National Lead Co. of Ohio	9 years	Production
U238	Tons	National Lead Co. of Ohio	9 years	Production
C060	1 Curie	National Lead Co. of Ohio	9 years	Research
Sr90	200 MC	National Lead Co. of Ohio	9 years	Research

10. RADIATION DETECTION INSTRUMENTS (Use supplemental sheets if necessary). SEE ATTACHED

TYPE OF INSTRUMENTS (Include make and model number of each)	NUMBER AVAILABLE	RADIATION DETECTED	SENSITIVITY RANGE (mr/hr)	WINDOW THICKNESS (mg/cm^2)	USE (Monitoring, Surveying, Measuring)
				SEE ATTACHED	

11. METHOD, FREQUENCY, AND STANDARDS USED IN CALIBRATING INSTRUMENTS LISTED ABOVE. SEE ATTACHED

12. FILM BADGES, DOSIMETERS, AND BIO-ASSAY PROCEDURES USED (For film badges, specify method of calibrating and processing or name of supplier). SEE ATTACHED

INFORMATION TO BE SUBMITTED ON ADDITIONAL SHEETS SEE ATTACHED

13. FACILITIES AND EQUIPMENT. Describe laboratory facilities and remote handling equipment, storage containers, shielding, fume hoods, etc. Explanatory sketch of facility is attached (Circle answer). Yes No SEE ATTACHED

14. RADIATION PROTECTION PROGRAM. Describe the radiation protection program including control measures. If application covers sealed sources, submit leak testing procedures where applicable, name, training, and experience of person to perform leak tests and arrangements for performing initial radiation survey, servicing, maintenance and repair of the source. SEE ATTACHED

15. WASTE DISPOSAL. If a commercial waste disposal service is employed, specify name of company. Otherwise, submit detailed description of methods which will be used for disposing of radioactive wastes and estimates of the type and amount of activity involved. SEE ATTACHED

CERTIFICATE

(This item must be completed by applicant)

.....
Applicant named in Item 1

Date ..... By: .....

.....
Title of certifying official authorized to act on behalf of the applicant

11. Method, Frequency, and Standards Used in Calibrating Instruments

Gas proportional counters are calibrated originally at the Factory utilizing Polonium 210. Thorium 230 alpha source with a ¾" active area and 3500 CPM is used to calibrate instruments prior to each use. The exact value of the source is marked on the face of the source. The source is placed within one quarter inch from the window face for field calibration.

The Victoreen Radector 500 is calibrated with 100 MC CS^{137} gamma radiation source every six months.

The high volume sampler is calibrated against a known volume of CFM flowed through an orifice.

12. Film Badges, Dosimeters, and Bio-Assay Procedures Used

The name of the supplier and processor of the film badges is Eberline Instrument Corporation, P. O. Box 2108, Santa Fe, New Mexico 87501.

13. Facilities and Equipment

The magnesium-thorium metal will be processed and machined on lathes, drills, drill presses, etc. Adequate ventilation will be afforded each operation where magnesium-thorium is processed. All magnesium-thorium will be properly identified, stored and handled in accordance with safety standards.

14. Radiation Protection Program

The radiation protection program is administered by a trained and qualified Health Physicist designated as the Radiation Protection Officer. Radiation surveys are periodically conducted in all areas where radiation exist or is thought to exist. The surveys consist of swipe sampling of all operations utilizing radioactive materials. Film badges are provided to all personnel assigned to the program. A safety orientation is also provided to personnel assigned to the program.

15. Waste Disposal

The disposal of all radioactive waste material shall be in accordance with the State of Colorado rules and regulations pertaining to radiation control. Certificate Disposition of Radioactive Materials, Form AOR-RH-23 (1-68-5) shall be used for proper disposal of radioactive materials.

Form AEC-313
8 64
10 CFR 30

UNITED STATES ATOMIC ENERGY COMMISSION

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved
Budget Bureau No 38-R027

INSTRUCTIONS - Complete items 1 through 16 if this is an initial application or an application for renewal of a license. Information contained in previous applications filed with the Commisson with respect to items 8 through 15 may be incorporated by reference provided references are clear and specific. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail two copies to U.S. Atomic Energy Commission, Washington, D.C. 20545, Attention: Isotopes Branch, Division of Materials Licensing. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30, and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1 (a) NAME AND STREET ADDRESS OF APPLICANT (Institution, firm, hospital person, etc. Include ZIP Code.)

Martin Marietta Corporation
Denver Division
Waterton Facility, Box 179
Denver, Colorado 80201

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED (If different from 1 (a) Include ZIP Code.)

Martin Marietta Corporation
Denver Division
Waterton Facility, Box 179
Denver, Colorado 80201

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Propulsion Cold Flow Lab.

3. PREVIOUS LICENSE NUMBER(S). (If this is an application for renewal of a license, please indicate and give number.)

Renewal - License No. 5-3010-4(B67)

4. INDIVIDUAL USER(S). (Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)

Allen L. Hobbs or individuals designated by Allen L. Hobbs

5. RADIATION PROTECTION OFFICER (Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)

Allen L. Hobbs
Elmer N. Chenault

6. (a) BYPRODUCT MATERIAL (Elements and mass number of each)

Cesium -137

(b) CHEMICAL AND OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. (If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)

Sealed sources (Ohmart Corporation Model No. Lab - 236 - C1 - 4 700 millicuries) 2 sources of 300 millicuries and 1 source of 100 millicuries.

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. (If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)

To be used in the Ohmart Corporation Model No. SHP-P source holders for detection of gas related to oxidizer tanks.

(Continued on reverse side)

The supervisor assigned to the decontamination program is Mr. H. Kaiser, who has many years' experience working in the area of hazardous materials auch as beryllium, acids, and radioactive matter.

C. Operators - Martin Marietta Corporation

All operators assigned to the program have received a radiological health orientation and are familiar with the health aspect of uranium. Most of the operators have worked with and around various types of hazardous materials.

APPLICATION FOR GENERAL LICENSE TO RECEIVE, POSSESS, USE AND TRANSFER SPECIAL NUCLEAR MATERIAL (PART 70, CFR 10)

I. The Martin Company is engaged in design, research, development and construction of nuclear reactors and nuclear components at its Middle River Plant near Baltimore, Maryland. For the purpose of development and fabrication of reactor fuel elements, a Nuclear Materials Laboratory and a Pilot Manufacturing Plant have been constructed in the basement of "D" Building at Plant I. A critical experiment facility for zero power testing of proto-type reactor cores is in the final stage of completion. This facility is located near the Martin airport some two thousand feet southeast of Plant I.

Research and development work on fuel elements is conducted under Special Nuclear Material License No. 11, as amended, in accordance with procedures described in the Company's applications of May 22, 1957 and September 19, 1957. The most recent revision of this license permits special operations involving fully clad fuel elements to be performed in the pilot manufacturing plant and in other buildings at Plant I in addition to the laboratory areas.

Initial operation of the Pilot Manufacturing Plant involves fabrication of stainless steel tubular elements containing highly enriched UO_2, for a proto-type MPR core to be tested to zero power for the Atomic Energy Commission under Contract AT (30-3)-277. Government-owned fuel has been handled through Accountability Station MND, which was authorized by the Schenectady Operations Office after approval of the Martin Nuclear Division's procedures regarding criticality control, accountability, health and safety, and security.

In addition to MPR type tubular elements, The Martin Company plans to fabricate other fuel element types in the Pilot Manufacturing Plant. Certain special operations will be performed in other buildings at Plant I. Some of the work to be undertaken will be on a commercial basis and therefore must be done under a Special Nuclear Material License issued by the Commission. In this connection, note is made that the Commission issued SNM License 53 to The Martin Company on November 26, 1956 permitting receipt and possession of fifty (50) kilograms of UO_2 enriched to over 90% in the isotope U235.

Several types of fuel elements including rods, tubes and plates will be manufactured. These elements will utilize uranium metal or uranium dioxide in a fuel marrow clad with such materials as stainless steel, aluminum alloys and zirconium alloys.

DOCKETED USAEC Division of Civilian Application DEC 13 1957 Docket Officer

In view of these varied contemplated activities, The Martin Company pursuant to Part 70, CFR 10 hereby applies for a general license to receive, possess and use up to five hundred kilograms of contained U235 in special nuclear materials at its Middle River facilities, including uses in the Critical Experiment Facility other than activities licensed under Part 50, CFR 10. Application is made for a license extending for three years from date of issuance. The experience gained by the Nuclear Division during the past three years in safe handling of nuclear materials is reflected in the general procedures outlined in this application in sections which follow.

II. Information required pursuant to Section 70.22, Title 10, Chapter 1, CFR:

(1) Applicant is The Martin Company, Baltimore 3, Maryland incorporated in the State of Maryland and having its principal plant and place of business at Middle River, Maryland.

Principal officers are:

G. M. Bunker, President, The Martin Company, Baltimore 3, Maryland - USA

W. B. Bergen, Executive Vice President, The Martin Company, Baltimore 3, Maryland - USA

W. L. Lucas, Secretary and Treasurer, The Martin Company, Baltimore 3, Maryland - USA

The Martin Company is not owned, controlled, or dominated by an alien, a foreign corporation, or foreign government. The applicant is the real party in interest and is not making this application as an agent for any undisclosed principal.

(2) Activities:

Attached for reference are plans of the nuclear facilities at the Martin Middle River plant showing work areas and quantities of special nuclear material (in terms of contained isotope U235) permitted in each work area:

Plate 1 - Plan of Engineering Materials Laboratory
Plate 2 - Plan of Pilot Manufacturing Plant
Plate 3 - Plan of Critical Experiment Facility located near Martin airport.

General procedures in connection with activities contemplated are:

(a) Receiving -

SNM will be received at Gate 5 of Plant I by the Accountability Representative. After monitoring by Health Physics Services for radiation hazards, shipments will be conveyed to Vault Annex Room, (Work Area IB) or Vault, (Work Area IA) for unpacking and weighing of special nuclear material.

(b) Storage -

The storage vault is a fully enclosed room, 22'8" by 13'9" by 11'0" high. It is designed to hold up to 600 kilograms of enriched uranium in powders, foils, elements or ingots stored in birdcage devices approximately 12" x 12" to 17" x 17" in cross-section. Walls, ceiling, and floor are constructed of a minimum of 9 inches of reinforced concrete. Sole entrance to the vault is through a $1\frac{1}{2}$" steel door equipped with a three-way combination lock. There are no water or service piping or drains within the vault.

Materials will be stored in separate containers containing quantities which are less than the theoretical critical masses calculated for optimum conditions with respect to geometry of container, moderators, and reflector according to the calculating procedures outlined in the Martin Criticality Precautions Manual, MND-1063 (Appendix A) and its reference "A Guide to the Calculation of Criticality Limits for Enriched Uranium" by Dr. Chernick. Each container will be at least 12" x 12" in cross-section with a length about 12" longer than the material to be held. Containers and birdcages will vary in design according to the form of the material. For example:

Uranium dioxide powders will be stored in metal bottles of approximately 150 cubic centimeters capacity. No more than 600 grams of uranium dioxide enriched to over 90% in the isotope U235 or more than 550 grams of contained isotope U235 will be stored in each metal bottle. One and only one bottle will be suspended inside a cubical "birdcage" type structure of welded metal construction having dimensions of 16 5/8" x 16 5/8" x 21 3/8".

Uranium metal foil will be stored in birdcages 12" x 12" x 34" with bundles of foil each containing no more than 1000 grams of U235 held roughly in the center by inserts.

Fuel elements, tubular or plate, will be held in cradles in storage devices or similar dimensions (12" x 12" x 30-40"). Each cradle will hold a prescribed number of tubes or plates, the total U235 content of which will be within the allowable limits established for the particular form of material involved.

Solid scrap will be stored in metal boxes 9 1/2" x 11 3/4" x 26", each held in a birdcage 12" by 12" x 40" long.

Insofar as it is practical, all birdcages will be placed in rows along the walls of the vault to permit easy access. The lowest rows will be placed on platforms about 17 inches above the floor to prevent accidental contact with water. Even if flooding occurred above the height of 22" required to reach any special nuclear material, no hazard would exist since (1) all materials will be in latched birdcages in amounts less than the theoretical critical limits and (2) powders will be in water-tight metallic containers within the birdcages.

All material will be stored during non-work hours either in the vault or in locked repository safes in the manufacturing area.

When special nuclear material must be taken from the nuclear facilities to other areas within the Martin plant, it will always be in the custody of a "Q" cleared accountability designee.

(c) Forms of material -

Forms with corresponding allowable limits in contained U235 have been established as shown on the following two pages.

(d) Work Areas and Criticality Control -

Reference is made to Plates 1, 2 and 3 and to the Martin Criticality Precautions Manual, MND-1063, filed with the AEC, April 22, 1957. A revised copy of this manual is attached as Appendix A. The manufacturing area and the critical experiment area have been divided into Work Areas for purposes of control of criticality. The laboratory except for a few designated work areas is considered to be one integral work area. Limits (in terms of U235) are shown on the plates for the various

FORM	ENRICHMENT OF URANIUM IN ISOTOPE U235	TYPE OF MATERIAL	ALLOWABLE LIMIT IN ANY WORK AREA (grams of contained U235)
Ia	all enrichments	UO_2 powder, density when loose approx. 5 gr/cc	800 grams
Ib	all enrichments	UO_2 powder, pressed and sintered shapes density approx. 10 gr/cc	800 grams
Ic	0.72% to 20.0%	UO_2 and ThO_2, powder and sintered shapes	* grams
IIa	highly enriched	UO_2 and stainless steel mixture, density approx. 8.4 gr/cc	1600 grams
IIb	highly enriched	Sintered cermet of UO_2 and stainless steel density approx. 8.4 gr/cc	1850 grams
III	all enrichments	Uranium in aqueous solution	2 grams/liter (1)
IV	highly enriched	Stainless steel clad tubes, with Form IIb as fuel marrow	2000 grams
V	over 20.0%	Stainless steel clad plates with uranium metal as fuel marrow	1600 grams
VIa	over 20.0%	Uranium metal in thin forms; ribbon, foil wire, etc.	500 grams
VIb	over 20.0%	Uranium metal in fine cuttings, dust., etc.	500 grams
VIIa	all enrichments	UO_2 and powdered Al mixture, approx. density 2.5 gr/cc	800 grams
VIIb	all enrichments	Pressed or sintered UO_2 and Al mixture in (VIIa) approx. density 5.0 gr/cc	800 grams

FORM	ENRICHMENT OF URANIUM IN ISOTOPE U235	TYPE OF MATERIAL	ALLOWABLE LIMIT IN ANY WORK AREA (grams of contained U235)
VIIIa	all enrichments	Aluminum alloy clad tubes with Form VIIb as fuel marrow	800 grams
VIIIb	all enrichments	Iron-aluminum alloy clad tubes with Form VIIb as fuel marrow	800 grams
IX	over 20.0%	Uranium metal in buttons, derbies, etc.	10000 grams (2)
X	over 20.0%	Uranium metal in ingots, bars, machined shapes, smallest dimension 70.25 inches	3000 grams
XI	0.72% to 20.0%	Stainless steel clads filled with solid pellets of Form Ib or Ic	2000 grams
XII	over 20.0%	Zirconium, titanium, molybdenum and other "special" alloy-clad plates with uranium metal fuel marrow	grams (3)
XIII	over 20.0%	Uranium-thorium molybdenum alloys	grams (3)

(1) Except when total amount in any one container in all forms is less than 400 grams of U235

(2) Subject to review with regard to minimum dimensions and reflecters

(3) To be determined

forms of SNM (pages 5 and 6) which can be present in each work area at any one time. In the event that several forms are present at one time in a work area, the lowest allowable limit for U235 applies to all materials present.

All transfers between work areas are made by the courier acting as a designee of the Accountability Representative. Enforcement of criticality procedures within work areas is a responsibility of each facility supervisor. Material, under close weighing control, is transported to an "Off-Spot" in work boxes in "carrier" devices. Amounts present in each work area are shown on prominent signs posted by the Accountability Representative.

(e) Manufacturing -

Fabrication of fuel elements will be performed in the pilot shop located in "D" Building.

A few special operations such as brazing of fully clad tubes to end castings will be done in other buildings at Plant I.

Processes, either developed or being developed include:

(1) Fabrication of stainless steel clad plates enclosing uranium metal foil (Form I)

(2) Stainless steel clad tubes enclosing fuel marrow of enriched uranium dioxide-stainless steel cermet (Form IV)

(3) Aluminum and aluminum alloy clad tubes enclosing pressed uranium dioxide-aluminum blended compacts as fuel marrow (Form VIII)

(4) Stainless steel clads filled with solid compacts of uranium dioxide or uranium dioxide and thoria (Form XI)

General descriptions of these processes are outlined in Appendix B with corresponding manufacturing flow charts shown in Appendix C.

(f) Accountability -

The Martin Nuclear Division accountability procedures for strict control of valuable special nuclear materials

apply to both government-furnished SNM and to licensed SNM. Each lot received is assigned a ledger number. All material withdrawn is kept separate from other lots throughout processing. Scrap is kept segregated by contract or project. Thus there is no risk of intermingling materials or several contracts or of different enrichments.

(g) Security -

All facilities are controlled areas with only authorized personnel permitted access. An escort-control pass system is applied to authorized visitors.

Materials are given security protection in accord with the categories outlined in the AEC manual.

(h) Transport to Critical Experiment Facility -

Finished fuel tubes, plates or rods are moved to the facility in "birdcage" transporting devices in a guard-escorted motor vehicle. No more than 800 grams of U235 contained in sealed elements are allowed per "birdcage" device. These birdcage devices are 12" by 12" by 34" and retain in a center position wooden cradles 9 1/2" by 11 3/4" by 23 3/4" which hold the fuel tubes or plates.

(i) Receipt and Storage at Critical Experiment Facility -

After verification by the Accountability Designee of the Facility of the number of tubes or plates delivered the birdcages will be placed in the storage vault. The vault is of similar construction to the vault in the pilot manufacturing plant and has a floor area of 175 square feet. It is accessible only through a 1 1/2" steel door equipped with a three-way combination lock.

(j) Assembly at Critical Experiment Facility -

Tubes or plates are assembled into experimental bundles in Work Area 102, adjacent to the Storage Vault and Test Cells.

Following assembly, the fuel elements (bundles or boxes) will be placed in wooden cradles which are held in the birdcage storage devices. The dimensions of the cradle holding a bundle of thirty-seven (37) MPR tubes are 9 1/2" by 11 3/4" by 23 3/4".

The birdcage devices are then transferred to the storage vault for retention until withdrawal for experimental work authorized by a Class 104 c license.

(k) Shipping procedures -

Shipments of special nuclear material to the Commission or to other licensees will be made as follows:

(1) If the shipment contains no more than 100 grams of U235, the material will be securely packed in a container with resilient material between this container and the outside package. In addition, the parcel will be checked for possible radiation hazards and marked in accordance with ICC regulations.

No more than one package containing up to 100 grams of contained U235 will be transported or delivered to a carrier in any one shipment.

(2) If the shipment contains over 100 grams of U235, the material, depending on its form, will be packed in a container in either one of the Martin "birdcage" devices described in part 2(b) or an equivalent device to be furnished by the shipper. The quantity of U235 in any shipping device will be within the allowable limits for various forms shown on pages 7 and 8 of the manual, MND-1063.

(3) A general license is requested for a period of three years.

(4) Special Nuclear Material will be used in the forms shown in section 2(c). The general categories are:

Uranium dioxide powder; low-enrichment to over 90% enriched in isotope U235
Uranium metal foil, ribbon and wire; low-enrichment to over 90% enriched in isotope U235
Uranium metal ingots, slugs, billets, bars, derbies; all enrichments.

It is not possible to estimate amounts of each type required. However, a total requirement at one time of up to 500 kilograms of contained U235 in SNM is foreseen.

(5) The contemplated requirements for Special Nuclear Material for the last quarter of 1957 and the first quarter of 1958 are shown on the next page.

(6) The Martin Nuclear Division has been engaged in handling special nuclear materials for over two years in research and development of fuel elements. The new laboratory and pilot manufacturing plant have been in operation since June, 1957.

Several new concepts of fuel elements have been developed including the highly-enriched stainless steel clad, UO_2 cermet marrow tubular type. The first core loading of 1700 of these tubes will be completed in November. The technical staff of the Nuclear Division includes some 200 engineers. The manufacturing plant supervisor has had fifteen years of precision shop experience. Health Physics personnel include two senior health physicists each with over 5 years of training at AEC and industrial installations. The Accountability Representative is a public accountant with 10 years experience including 9 months in the handling of nuclear materials.

(7) Equipment and facilities used to protect health and safety -

Storage facilities are described in (2b) and (2i). The manufacturing and laboratory areas are under negative pressure with respect to adjacent working areas of "D" Building. Air flow is from non-contaminated areas to slightly-contaminated areas to more-contaminated areas, with the highest ventilation rates in those rooms or areas where the greatest air-borne contamination is possible.

Exhaust air that may contain appreciable radioactive particulate matter (that is from the hoods or dry boxes) is passed through absolute filters before being released to the atmosphere.

Hoods are used for handling uranium dioxide powders. These hoods, exhausting ducts and glove boxes are equipped with absolute filters. Machining of uranium metal will be done using an oil bath.

A partial list of available instruments and equipment appears as Appendix D.

MATERIAL	ENRICHMENT	QUANTITY ON HAND	4TH QUARTER 1957		1ST QUARTER 1958	
			Receipts	Returns	Receipts	Returns
UO_2 Powder	20%	5 kg	-	3	-	2
UO_2 Powder	over 90%	50 kg	20	25	10	25
Uranium foil	over 90%	0.5 kg	-	-	-	-
Uranium foil	over 90%	-	31	-	-	-
Uranium metal ingot	31%	-			40	40
Uranium metal ingot	over 90%	-			100	100

(8) Health and Safety measures -

Personnel working with radioactive materials (including SNM) or in radiation areas are routinely monitored for external radiation exposure by means of film badges and pocket chambers. Contamination is controlled by surveying likely objects or areas with appropriate detecting instruments or by making filter paper smears (which must be counted with an appropriate detector), recording results, and informing proper supervision. All operating personnel must be constantly alert to contamination possibilities involved in their operations and must continually strive to keep contamination to a minimum. Health Physics takes air samples in areas where airborne contamination is possible (frequency of sampling depends on operation). A tolerance of no more than 5×10^{-11} microcuries per milliliter air is established. If this tolerance is approached all personnel in the area affected are required to wear respirators. Uranium urinalyses and blood tests will be made every three months to check on internal deposition on people assigned to work in these areas.

From receipt of material to shipping or storage, Health Physics will be concerned with contamination and radiation levels from the SNM. External radiation measurements will be made on the received package and recorded. The Accountability Representative will open these packages. Health Physics shall assist in examination for breakage or other damage and subsequent contamination control in case of damage. During weighings of received SNM, Health Physics will make necessary smear checks. Samples to be sent for outside laboratory analysis will be packaged to conform with all pertinent ICC regulations.

Contamination control effectiveness will be checked by Health Physics throughout the operations in the laboratory and in the pilot manufacturing plant.

Protective clothing will be used to reduce personnel contamination.

Disposal of radioactive wastes: There will be no radioactive gaseous effluent from the Martin facilities. The incineration of radioactive combustible materials will be controlled by monitoring the exhaust stack of the incinerator.

Liquid wastes will be stored in polyethelene lined 55 gallon drums until ready for concentration. Batches containing no more than 400 grams of U235 will be reduced nearly to dry salt and these residues will be sent to AEC installations for recovery.

Solid wastes such as incinerator ashes will be mixed with a prepared cement mix before disposal by land or sea burials in accordance with Part 20, CFR 10.

The large volumes of slightly contaminated liquid wastes from the Decontamination Laundry will be held in collecting sumps until filtered, sampled, and counted for radioactivity before discharge to the sanitary sewer. Tap water dilution will be used, if necessary, to reduce the concentration to the levels required by 10 CFR Part 20.

(9) Emergency procedures -

An outline of the procedures to be followed in case of incidents involving nuclear materials is contained in the Criticality Precautions Manual, MND-1063, pages 5 and 5a.

(10) Financial Qualifications -

The Martin Company has done business under its present charter in the State of Maryland for a period of over twenty-five years. Total current assets on December 31, 1956 were $96,000,000 and sales for the year totalled about $360,000,000. The Nuclear Division, headed by a General Manager, is part of the company organization and draws its budgetary support therefrom.

The Martin Company will assume financial responsibility for all special nuclear materials received and will pay to the Commission the presented use charge based on the value of the material until the material is returned to the latter.

A copy of the 1956 Annual Report of the Company is attached as Appendix E.

III. Pursuant to Section 70.32, The Martin Company stipulates that:

(1) Title to all special nuclear material shall at all times be in the United States.

(2) No right to the special nuclear material shall be conferred by the license except as defined by the license.

(3) Neither the license nor any right under the license shall be assigned or otherwise transferred in violation of the provisions of the act.

(4) All special nuclear material shall be subject to the right of recapture or control reserved by section 108 and to all other provisions of the act.

(5) No special nuclear material may be used in any utilization or production facility except in accordance with the provisions of the act.

(6) The licensee shall not use the special nuclear material to construct an atomic weapon or any component of an atomic weapon.

(7) The licensee will hold the United States and the Commission harmless from any damages resulting from the use or possession of special nuclear material by the licensee.

(8) The license shall be subject to, and the licensee shall observe, all applicable rules, regulations, and orders of the Commission.

I certify that the statements made in this application and its attachments are true, complete and correct to the best of my knowledge and belief, and are made in good faith.

THE MARTIN COMPANY

APPENDIX B

DESCRIPTION OF PROCESSES EITHER DEVELOPED OR BEING DEVELOPED

(1) Stainless steel clad plates enclosing enriched uranium metal foil, Form V.

The process is diagrammed in the flow sheet for Form V, Appendix B. Material is received from processor in clean flat strips of foil, (Form VI) cut to size and enclosed in polyethylene bags. It is stored in birdcage boxes, 12" x 12" x 34" in lots not exceeding 1000 grams of U235 per container. Batches not exceeding 500 grams of contained U235 are withdrawn from storage vault, (Work Area 1a) and transferred by courier to Work Area 10 for assembly between stainless steel plates. Assembly is seam welded, evacuated at a low temperature and a final end seam weld made in Work Area 10. After radiography in Work Area 7, batches of plates will be autoclaved in Work Area 22 to determine porosity reliability.

Destructive and non-destructive testing will be performed on selected plates in Work Area 11.

(2) Stainless steel clad tubes enclosing fuel marrow of enriched uranium dioxide-stainless steel cermet (Form IV).

A description of the process is contained in the confidential manual, MND-1069 which is furnished as a supporting document to this application, (Appendix F). A flow sheet for the process is also included in Appendix C.

(3) Aluminum and aluminum alloy clad tubes enclosing pressed UO_2 -Al blended compacts (Form VIII).

Enriched uranium dioxide is blended with three parts by volume of powdered aluminum in Work Area 2. This blend is compacted to pressed bushings in Work Area 5. The bushings are assembled on a tube of aluminum or aluminum alloy and a second tube is passed over the bushings to complete the assembly. The assembly is swaged and drawn in Work Area 4 and then annealed to complete the metallurgical bonding in Work Area 5. Cleaning of the finished tubes is accomplished in Work Area 9. After radiography in Work Area 7, the assembly is sheared to size (Work Area 4) and the ends seam-welded in Work Area 10. Radiography, non-destructive testing, and porosity testing are done in Work Areas 7, 11 and 20 respectively to complete the tube manufacturing process. Brazing and welding of sealed tubes into bundles will be done in other facilities at Plant I under security and health safety safeguards required.

(4) Stainless steel cladsfilled with pressed compacts of uranium dioxide or uranium dioxide and thoria (Form XI).

Uranium dioxide powder of low enrichment in the isotope U235 is pressed into pellets. These pellets are assembled in stainless steel tubes and the interstices filled with a liquid metal to provide for efficient heat transfer between the fuel and the outside tube.

(An alternate method using ground pellets fitting to close tolerances in the tube may be used.)

The ends of the tubes are welded in Work Area 10 and the completed tubes are radiographed, porosity tested and cleaned.

Notice of Special Meeting of Stockholders

TO THE STOCKHOLDERS:

Notice is hereby given that a Special Meeting of the stockholders of The Martin Company will be held on October 9, 1961 at 11:00 o'clock a.m., Eastern Daylight Saving Time, at the offices of the Company, Middle River, Baltimore County, Maryland, for the following purposes:

(1) To consider and take action upon the proposed Articles and Plan of Consolidation (the Plan) of The Martin Company with American-Marietta Company, an Illinois corporation, declared advisable by the Board of Directors, pursuant to which a new corporation to be designated Martin-Marietta Corporation will be formed under the laws of the State of Maryland. The new corporation when so formed will issue shares of its stock to stockholders of The Martin Company and American-Marietta Company in accordance with the Plan, and will succeed to all of the assets of The Martin Company and American-Marietta Company and assume all of their respective liabilities.

(2) To transact such other business as may properly come before the meeting.

Only stockholders of record at the close of business on August 30, 1961, the record date fixed by the Board of Directors, will be entitled to vote at the Special Meeting.

By Order of the Board of Directors

W. L. LUCAS, *Secretary*

Middle River, Maryland

August 30, 1960

Approval by the holders of a majority of the total number of shares outstanding on August 30, 1961 is required to approve the proposed consolidation. Whether or not you plan to attend the Special Meeting of the stockholders, you are requested to sign and return at once the accompanying Proxy. If you do attend the meeting, you may vote there in person should you so desire.

A/69

PROXY STATEMENT
FOR SPECIAL MEETING OF STOCKHOLDERS
TO BE HELD OCTOBER 9, 1961

There is enclosed herewith a Notice of a Special Meeting of Stockholders of The Martin Company (herein called "Martin") to be held at the offices of the Company, Middle River, Baltimore County, Maryland, at 11 o'clock A.M. Eastern Daylight Saving Time October 9, 1961, and a proxy for the special meeting. The meeting has been called to take action on the proposed consolidation of Martin with American-Marietta Company (herein called "American-Marietta"), an Illinois corporation, into a new corporation to be designated Martin-Marietta Corporation (herein called the "Consolidated Company") which will be formed under the laws of the State of Maryland, the Consolidated Company to succeed to all of the assets of Martin and American-Marietta and assume all of their respective liabilities.

At the Special Meeting Articles and Plan of Consolidation will be submitted to the stockholders for adoption.

REASONS FOR CONSOLIDATION

During the past decade, Martin has experienced rapid growth in the fields of missiles, aerospace and allied electronics and nucleonics activities. The management of Martin is confident that it has the technological capability to remain in the forefront of these activities.

Martin management feels that it now has reached the size and financial position where, for the long term, it should broaden the base of its operations to include major participation in the industrial and commercial growth of the economy. Diversification now and new growth areas for the future are the primary factors which influenced the directors of both companies to approve the proposed consolidation.* American-Marietta's sales in the past decade have grown from $66 million to $368 million and its profits have increased from $2.8 million to $24 million. It is a leading factor in a number of basic growth industries, including paints, industrial finishes, household cleaning products, synthetic resins and adhesives, chemicals as more fully described below, cement, printing inks and a wide variety of building and construction materials. The proposed consolidation offers a unique opportunity to establish a broadly diversified company and there are additional benefits mentioned below that Martin's management believes will result from the consolidation.

Research and New Markets

Both Martin and American-Marietta maintain strong research programs in the development of new materials and products, but to date, Martin because of its lack of commercial outlets, has not been able to translate the application of its technical activities in the commercial market. Its management envisages new opportunities in research and product dvelopment that should result in the application of some of Martin's technical developments for civilian application. There can be no assurance, however, that the consolidation will enable Martin to find commercially profitable outlets for the application of its technical activities. Likewise, American-Marietta's improvements in materials and structural design may fill some of the complex needs of aerospace technology.

Depth of Management

It is believed there is strength and depth of management in both companies—each fully competent in its primary fields of activity and each able to complement the other in achieving the objectives of the Consolidated Company. Under the leadership of Mr. Grover M. Hermann, American-Marietta management has accomplished the growth set forth above.

In the organization and operating structure of the Consolidated Company, it is contemplated that Martin and American-Marietta will each maintain its identity with respect to the management, conduct of its business and customer relations. It is presently contemplated that all of the executive officers of each company will be retained in an executive or administrative capacity and that the various divisions of each of the companies will continue to be operated as separate divisions under the supervision of

* Announcement of these approvals on June 23, 1961 was the first public disclosure of the proposed consolidation.

the persons presently charged with primary responsibility for the conduct of the same. The existing employment agreements between Martin and Messrs. George M. Bunker and Clarence W. Miles (hereinafter on page 22 more fully described) will be assumed by the Consolidated Company which becomes responsible for the compliance with the terms and conditions thereof.

Stronger Corporate Structure

The financial structure of the Consolidated Company, with estimated annual sales based on present operations in excess of $1 billion and total assets of over $500 million, will provide a strong base for such future activities as may be desirable to permit the further growth of the company's business. In addition, the consolidation will generate a cash flow of sizeable proportion, a total of $68 million for the two companies in 1960.

Benefits To Martin Stockholders

Under the terms of the consolidation, Martin stockholders would receive 1.3 shares of common stock of the Consolidated Company for each share presently held, and American-Marietta common stockholders would receive a share-for-share exchange. In arriving at such exchange ratios, consideration was given to the diversity of the businesses of the constituent companies, the earnings of each company for the current and preceding five (5) years, the market values of the shares of each company prevailing during the said period, the book value of each company's common stock and the prospective earnings for each company for 1961 and 1962. Such consideration resulted in the conclusion by the respective managements of the two companies that the aforementioned basis of exchange was an equitable one. (See pages 17-19 hereof with respect to Per Share Earnings, Book Value of Common Stocks and Price Range of Common Stocks). The American-Marietta Class B stock would be eliminated and its holders would receive 4½% Cumulative Preferred Stock (non-convertible) of the Consolidated Company. The book value of such stock at November 30, 1960 was $13.09 per share or an aggregate book value of $42,106,637. It was the best judgment of the respective managements of the two companies, having in mind the dividend limitation (See page 24) and the lack of a market for the Class B Common Shares, as well as the probability that the 4½% Cumulative Preferred Stock to be issued would have a market value less than the par value thereof, that a fair and equitable basis of exchange would be one whereby holders of Class B Common Shares would receive shares of 4½% Cumulative Preferred Stock (non-convertible) of the Consolidated Company representing approximately 90% of the book value of said Class B Common Shares or $38,000,000. This basis of exchange represents approximately 12/100ths of a share of the new preferred stock for each Class B Common Share. American-Marietta will redeem its outstanding 5% Cumulative Preferred Shares prior to the consolidation.

The effect of the consolidation at the outset would be a reduction in Martin's anticipated per-share earnings for 1961 to about the level of last year's per-share earnings which reflected an increase of 70 per cent over the past five years. However, the consolidation would provide Martin stockholders with an immediate 30 per cent increase in cash dividends based on the recent historical dividend record of both of the constituent companies, increased book value and prospects of long-term stability through immediate diversification and possible future expansion into new growth areas. Payment of dividends by the Consolidated Company is, of course, subject to future business conditions, the Company's earnings and financial condition.

It is the considered opinion of Martin's directors and management that the consolidation is in the best interest of all stockholders.

SUMMARY OF THE PLAN

At meetings held on August 3, 1961, the Boards of Directors of Martin and American-Marietta approved and recommended an Agreement of Consolidation dated as of August 1, 1961 (the Agreement), pursuant to which Martin and American-Marietta (the constituent companies) will be consolidated into a new Maryland corporation to be known as Martin-Marietta Corporation. At the same meeting the Martin Board of Directors adopted a resolution approving proposed Articles and Plan of Consolidation of the constituent companies (the Articles), setting forth the terms of such consolidation and declaring that the proposed consolidation is advisable substantially upon the terms and conditions set forth in the Articles. Copies of the Agreement and the Articles are attached hereto and marked

as Appendix 1 and Exhibit A to Appendix 1, respectively. The American-Marietta Board has approved the Agreement and the Articles.

Briefly stated, the Agreement provides that the title to all of the assets of the constituent companies will devolve upon the Consolidated Company, and the Consolidated Company will assume all of the liabilities of the constituent companies. The Consolidated Company will issue new shares of its capital stock to the holders of the common stock of the constituent companies. The presently outstanding 5% Cumulative Preferred Shares of American-Marietta will be redeemed and retired prior to the consolidation.

Capital Stock Outstanding before and after the Consolidation

On July 31, 1961 Martin had outstanding 6,258,829 shares of Common Stock without par value, which will be converted (on a 1.3 for 1 basis) into 8,136,478 shares of Common Stock of the par value of $1 per share of the Consolidated Company. Arrangements will be made for the matching and combination or the purchase and sale of fractional interests in respect of Martin certificates surrendered for exchange within 60 days after the consolidation becomes effective.

On July 31, 1961, American-Marietta had outstanding: (a) 200,599 5% Cumulative Preferred Shares, $100 par value per share. These shares will be redeemed. (b) 3,191,189 Class B Common Shares, $2 par value. It is anticipated that prior to the consummation of the consolidation but after the approval thereof by the stockholders of the constituent companies, 70,314 of these shares will be converted into an equal number of Common Shares and simultaneously therewith 70,314 of the outstanding Common Shares of American-Marietta will be surrendered to it as a capital contribution, with the result that there will be no net increase in the number of American-Marietta Common Shares outstanding. The remaining 3,120,875 Class B Common Shares will be converted into 380,000 shares of 4½% Cumulative Preferred Stock, $100 par value of the Consolidated Company. (c) 13,199,875 Common Shares, $2 par value, which will be converted into a like number of shares of Common Stock, $1 par value of the Consolidated Company.

The preferred stock to be issued by the Consolidated Company will not be convertible into shares of Common Stock. The terms, conditions and provisions of the 4½% Cumulative Preferred Stock are fully set forth in Article IV, subdivision SIXTH, of the Articles hereto attached.

Warrants and Stock Options

Holders of Warrant Certificates issued by Martin pursuant to its Indenture dated as of November 1, 1958, to Fidelity-Baltimore National Bank, as Trustee, will be entitled to subscribe for shares of Common Stock of the Consolidated Company in accordance with the terms of the Indenture.

Each Warrant upon the consolidation becoming effective will entitle the holder to subscribe for 2.73 shares of Common Stock of the Consolidated Company for $40 to and including November 1, 1963, and for $45 thereafter and to and including November 1, 1968. Shares of Common Stock will be reserved by the Consolidated Company for issuance upon the exercise of such Warrants.

Holders of stock options granted by Martin, upon the consolidation becoming effective, will be entitled to purchase from the Company 1.3 shares of Common Stock of the Consolidated Company in the place and stead of each share of Common Stock without par value of Martin which such holder was entitled to purchase immediately prior to the consolidation, subject, however, to such minor adjustment as may be necessary to preserve the "restricted" status of the stock options under the United States Internal Revenue Code. Shares of Common Stock will be reserved by the Consolidated Company for issuance upon the exercise of such stock options.

Effective Date

The consolidation will become effective after approval by the stockholders of the constituent companies at the special meetings to be held on October 9, 1961, and upon compliance with the laws of the States of Maryland and Illinois in relation to the filing of the Articles with the public authorities in those states.

Termination and Abandonment of the Consolidation

The Agreement may be terminated and the consolidation abandoned by resolution of the Board of Directors of either of the constituent companies if certain conditions of that company's obligations set forth in the Agreement are not satisfied. The Agreement may be terminated and the consolidation abandoned by the two constituent companies (each acting by its Board of Directors) by mutual consent, at any time before the consolidation becomes effective. In the event of any termination of the Agreement and abandonment of the consolidation, neither of the constituent companies shall have any liability to the other for costs, expenses, loss of anticipated profits, or otherwise, in connection with the Agreement.

It is not contemplated that the Agreement will be terminated or abandoned for any reason other than the failure on the part of either of the constituent companies to comply with its covenants and obligations thereunder.

BUSINESS AND PROPERTIES OF AMERICAN-MARIETTA

American-Marietta is engaged directly and through subsidiaries in the production, manufacture and sale of construction materials and products, a wide variety of chemicals and chemical products sold to numerous industries, and other miscellaneous products, all as more fully described below. The approximate percentage contribution of these three groups to consolidated net sales for the fiscal year ended November 30, 1960 were as follows: construction materials—44%, chemicals and chemical products—41%, miscellaneous products—15%. The number of persons employed by American-Marietta as of June 30, 1961 was 16,247.

Construction Materials

Cement. Portland cement is widely used in many types of construction. It is sold in bulk to ready-mix concrete producers and to contractors for use in building highways, airports, bridges, dams, waterways, military installations and other structures. Portland cement and mortar cement, used in brick and stone construction, are also sold to independent distributors and dealers.

Cement is produced by the following divisions of American-Marietta: Dragon Cement, with plants in Northampton, Pennsylvania, and Thomaston, Maine; Standard Lime & Cement, with a plant at Martinsburg, West Virginia; Southern Cement, with two plants near Birmingham, Alabama; and Dewey Portland Cement, with plants in Dewey and Tulsa, Oklahoma, and Davenport, Iowa. American- Marietta believes that reserves of limestone and cement rock adjacent to its various plants are sufficient for many years of operations at current levels.

Concrete products. These include machine and precast concrete pipe for sewers, culverts, water mains, irrigation lines and other uses; pre-stressed concrete bridge sections; concrete cribbing; and other structural elements of precast concrete. American-Marietta and its subsidiaries operate a large number of concrete products plants in the United States and Canada. The cement for American-Marietta's concrete products is largely purchased from other suppliers and not from American-Marietta's own plants. The products are generally sold direct to contractors and to states, municipalities and other governmental units.

Aggregates. Aggregates, meaning crushed stone, sand and gravel, are used in building highways, in other types of heavy construction and in making concrete. American-Marietta's principal quarries and crushing plants for producing these products are in North Carolina and Iowa.

Other construction materials and products. These include common and face brick; hollow and drain tiles; aluminum and architectural products and electrical construction products of American-Marietta's subsidiary, Steel City Electric Company, such as electrical outlet and switch boxes, floor boxes, conduit and cable fittings, and pipe and conduit hangers. The Master Builders Company division produces "Pozzolith", an additive to promote dispersion in concrete, which American-Marietta classifies as a chemical product.

Chemicals and Chemical Products

Paint, finishes and coatings. These products include primers, surfacers and finishes for use on automobiles, trucks, buses, farm machinery, railroad cars, prefabricated houses, office equipment, furni-

ture and appliances; heavy duty maintenance paint for industrial use; and chemical coatings made by the Stoner-Mudge division for lining cans and other metal containers for foods and beverages. A large part of the products in this group are produced to customers' specifications and sold directly to manufacturers, not only in the United States and Canada but also to a limited extent in France, Holland and other foreign countries.

Chemical lime, refractories and silica sand. The Standard Lime & Cement and Southern Cement divisions produce chemical lime, which is sold to the chemical and paper industries and to municipalities and industries for water and waste treatment; fluxing lime, crushed stone and magnesite for the steel industry; and clinkered dolomite used in refractories. Other divisions produce silica sand used in the manufacture of glass and for other purposes. As in the case of cement, American-Marietta believes that its reserves of raw materials for these products are adequate for many years of operations.

Printing inks. Many types of printing inks are manufactured by the Sinclair and Valentine division for use in printing and packaging. This division has numerous plants in the United States, a number in Canada, and operations in Mexico, Germany, Switzerland and South America.

Adhesives, resins and chemicals. This group of products includes synthetic resins, glues and adhesives which are sold to the plywood, paper and hardboard industries for bonding purposes.

Dyestuffs. The Southern Dyestuff ("SODYECO") division manufactures ready-to-use sulphur and vat dyes and other coloring materials for the textile industry.

Miscellaneous Products

Other industrial products. American-Marietta and its subsidiaries also manufacture sealants for the aircraft, automotive, construction, electrical communications, foundry, and household appliance industries; metallurgical products such as metal powders, pigments, abrasives and alloys used in the aircraft, missile, and automotive and other industries; machinery and equipment used in heavy construction and metal fabrication; and industrial cleaning products.

Consumer Products. Latex, Alkyd and oil base paints for use by consumers are produced and sold under a variety of trade names, including "American-Marietta", "Arco", "Valdura", "Rev Satin", "Jelled Magic", "Sewall", "O.P.W." and "Berry Bros." Sales are principally to jobbers and retail outlets. The O-Cedar division manufactures mops, polishes, waxes and other household institutional cleaning products.

Federal Trade Commission Proceedings

American-Marietta's business in cement, concrete products and aggregates and in lime and limestone products herein described stems originally from its acquisitions of numerous companies engaged in these businesses, although the acquired properties have been substantially enlarged under American-Marietta's ownership. On January 27, 1961 the Federal Trade Commission issued a complaint under Section 7 of the Clayton Act charging that American-Marietta's acquisitions may lessen competition or tend to create a monopoly in the above lines of commerce in various sections of the country and constitute unfair methods of competition under Section 5 of the Federal Trade Commission Act. To date, no hearings have been held, and American-Marietta has advised Martin that it cannot predict the outcome of the proceedings at this time. If the charges in the complaint were sustained, the remedies available to the Commission might include divestiture of certain of the acquired businesses. Under the provisions of American-Marietta's long term notes, if such a divestiture involved sale of a substantial part of the company's assets, the company would have to offer to apply the proceeds to retirement of an equal amount of its long term debt.

Research

American-Marietta puts substantial emphasis on research. New products and product improvements are sought through a program related closely to customer activities and requirements. To implement this program research activity is decentralized in 25 laboratories run by the operating divisions and subsidiaries. The approximate dollar amount spent on reasearch during the 1960 fiscal year was $4,150,000 not including dues paid trade associations, a substantial portion of which is spent on research in their respective industries.

Plants and Facilities

The plants of American-Marietta and its subsidiaries differ greatly in size and importance, depending upon the nature of the product manufactured. Its management considers them to be well maintained and in satisfactory condition. Most of the manufacturing facilities of American-Marietta are owned by it and, for the most part, are unencumbered. However 32 of the printing ink plants, 16 of the concrete products plants, 26 of the aggregates plants and 1 other plant are operated in leased premises. The locations of the principal plants and facilities are listed below.

BUSINESS AND PROPERTIES OF MARTIN

General

Martin is now primarily engaged in the design, development and production of guided missiles, electronics equipment, communications equipment, aerospace vehicles, and nuclear products.

Martin's military sales and sales to other customers for the past five calendar years and for the first six months of 1961 were as follows:

Year	Military		Other	Total
	Missiles, Electronics and Nuclear	Aircraft		
1956	$126,171,000	$231,869,000	$ 922,000	$358,962,000*
1957	245,796,000	177,054,000	1,075,000	423,925,000
1958	287,347,000	192,390,000	3,907,000	483,644,000
1959	410,125,000	111,083,000	2,499,000	523,707,000
1960	601,306,000	48,676,000	1,246,000	651,228,000
January–June 1961...	398,739,000	8,611,000	843,000	408,193,000

* Before adjustment of $2,387,891 as a result of renegotiation for the year 1956.

Martin's backlog of military and other orders at the end of each of the past five calendar years and at June 30, 1961 were as follows:

Year	Military		Other	Total
	Missiles, Electronics and Nuclear	Aircraft		
1956	$ 521,866,000	$289,148,000	$ 379,000	$ 811,393,000
1957	496,978,000	297,900,000	176,000	795,054,000
1958	597,934,000	232,071,000	1,514,000	831,519,000
1959	814,563,000	85,623,000	368,000	900,554,000
1960	1,004,081,000	22,283,000	414,000	1,026,778,000
June 30, 1961....	996,663,000	14,886,000	705,000	1,012,254,000

As the above tables indicate, missiles, associated equipment, electronic systems and nuclear products accounted for approximately 98% of Martin's total backlog of orders at June 30, 1961.

Martin's missile business includes a variety of products and weapons, those capable of massive destruction and usable as aerospace vehicles, and those capable of use in limited warfare. The missiles include those powered with jet engines, those powered with liquid fueled rockets and those powered with solid fueled rockets.

Mace

The Mace is an outgrowth of the Matador, one of the earliest missiles produced by Martin. The Mace is a highly mobile surface-to-surface tactical missile designed in two types (the Mace A and the Mace B) both of which have self-contained guidance systems. Associated with the Mace is a substantial volume of ground support equipment produced by Martin.

Bullpup

The Bullpup is a short-range, air-to-surface missile first developed and produced by Martin under contracts with the Navy. Versions of the missile are produced for use by the Air Force as well as the Navy, and it is now in operational use with the Navy, Marine Corps and Air Force. The function of the missile is to provide light attack aircraft with greater capability than was formerly available against tactical targets.

Lacrosse

The Lacrosse is a mobile and highly accurate surface-to-surface guided missile developed as a close support weapon for combat troops. The missile and its associated ground equipment have been

in production since 1957. The missile is propelled by a solid fuel rocket motor and is capable of delivering both nuclear and conventional warheads.

Titan

The Titan Intercontinental Ballistic Missile is a two-stage liquid fueled rocket powered missile designed to deliver a thermonuclear warhead to a predetermined point more than 6,000 miles from the launching site. Martin is responsible for the airframe, controls and associated ground support and launching equipment, as well as for the functioning of the system as a whole. Martin holds contracts with the Air Force for two types of the Titan missile. The first type, Titan I, is in production and is undergoing advanced flight tests. The Titan II will be larger than Titan I and will be able to carry a heavier payload over even greater distances than the Titan I. It is designed to utilize storable fuels which will make it possible to maintain the missile in a ready-firing condition for long periods of time at ordinary temperatures. It is also being designed for firing from underground sites.

Pershing

Pershing is the United States Army's selective range, surface-to-surface ballistic missile system having a "built-in" jam-proof guidance system. It consists of two stages employing solid propellants and is lighter, smaller, and more mobile than the Army's Redstone system which it is scheduled to replace. As systems contractor, Martin is responsible for research and development, reliability, testing and production of the missile and associated ground equipment.

Dyna-Soar

Dyna-Soar is an advanced boost-glide space vehicle. The Air Force has retained responsibility for the integration of the complete system. Martin has been selected to build the booster portion of the program and holds a contract for the Dyna-Soar launch rocket. The Titan II design will be modified to meet the requirements of the Dyna-Soar Program.

Electronics

Martin's capability in the field of electronics is founded on intensive research and development work begun during World War II and many years of experience in the design, testing, packaging, manufacture and field support of a wide diversity of electronic systems and components.

Martin's electronics activity is staffed by over three thousand five hundred engineers, supported by a full complement of technicians, apart from manufacturing and field service personnel. The engineers average five years of electronics experience with Martin. Electronic engineers in supervisory capacities average more than ten years of experience with Martin.

Major electronics programs have been conducted at Baltimore since 1946, at the Denver Division since its founding in 1956 and at the Orlando and Cocoa Divisions since 1957. A complete electronics staff and facility has been established in Baltimore.

One of Martin's major programs is the electronic system known as Missile Master, developed, produced and serviced under contract with the Army. The function of the system is the integration of anti-aircraft missile batteries for the air defense of the nation's principal industrial and population centers. Martin has completed delivery of the systems originally ordered, and now has an order for additional systems known as "BIRDIE", more compact but similar to the Missile Master.

Nuclear Activities

Martin's nuclear activities are centered at Baltimore where the Nuclear Division was formed in 1954 to provide emphasis on and control over those activities. Today the Division is organized in five product departments. During 1961 the Nuclear Powerplant Department is scheduled to complete two "packaged powerplants" under contract with the Atomic Energy Commission. The first of those, designated PM-1, will be installed at an Air Force radar station near Sundance, Wyoming. The other, known as PM-3A, will be shipped to McMurdo Sound, Antarctica. The advanced Reactor Systems Department is engaged under contract in research and development for a liquid fluidized bed reactor, the goal of which is to provide basically simpler operating techniques and significantly lower fuel costs than those involved in existing systems. The propulsion Systems Department is at work on several classified government projects, including its contribution to a study contract for the National Aeronautics and Space Agency in the RIFT (Reactor in Flight Test) program, under which plans are

being formulated for the flight testing of the first nuclear rocket engine. The Auxiliary Power Systems Department is producing a variety of direct conversion generators which require no moving parts. SNAP-3, the first such generator to use the decay heat of radioisotopes as a basic energy source, was delivered to the AEC early in 1959. As a result of the pioneer efforts in the development of SNAP-3, the Company has since developed similar generators that have been used in the first nuclear powered satellite (the Transit) and in the world's first radioisotope fueled weather station.

Research and Development

Martin's business depends greatly upon technological progress and great emphasis is placed upon research, engineering, development and testing. Therefore Martin has spent and expects to continue spending substantial sums of money in these areas. In addition to the programs described above, Martin has other research and development programs, some of which are in the very early research stage preparing Martin for future competitions for military products, while other programs have reached the stage of development, including the design and building of prototype military equipment. Among the outgrowths of these research and development efforts are two study contracts received within the past year: Project Apollo, designed to provide the capability for manned reconnaissance flights to the vicinity of the moon; and a contract for a study of SLOMAR, seeking the solution to the problems of providing freight, passenger, maintenance and rescue service for orbiting satellites and space stations.

As a part of its activities in the field of research, Martin's RIAS division is staffed with a selected group of scientists who create and conduct their own programs of research, including both theoretical and experimental studies.

Government Contracts

Substantially all of Martin's contracts with the Government are either the cost reimbursement type (cost-plus-a-fixed-fee) or the fixed priced incentive type.

The cost reimbursement type contract provides for reimbursement of costs (with certain exceptions) incurred in connection with the performance of the contract and a fixed fee specified in each contract. The fixed price incentive type contract provides for participation by Martin and the Government in either savings or excess costs with relation to an established target price.

Under fixed price incentive type contracts, Martin receives progress payments, generally in an amount equal to 70% of costs incurred. Martin's definitive cost reimbursement type contracts now provide for current reimbursement by the Government of 100% of costs incurred, and during the period of negotiation letter contracts provide for reimbursement of 70% of costs incurred.

The Renegotiation Act of 1951 as amended makes subject to renegotiation by the Government substantially all of Martin's profits through June 30, 1962, the present expiration date of the Act. Clearances under the Renegotiation Act have been received through the year 1952 with no refunds being required. Reference is made to Note A to Martin's earnings under "Summaries of Earnings" regarding required refunds and other information with respect to years subsequent to 1952 and for the year 1957.

Property

The Company's principal manufacturing plants are located near Baltimore, Maryland; Denver, Colorado and Orlando, Florida. Corporate offices, the Baltimore Division, and the Nuclear Division are located at Middle River, Maryland, approximately 12 miles east of the center of Baltimore. The facilities there provided comprise approximately 3,240,000 square feet owned by the Company and 157,000 square feet owned by the Government and operated by the Company under a Use Agreement. Property owned by the Government is made available to the Company without payment of rental unless the facilities are used for other than Government purposes. The land at Middle River owned by the Company aggregates approximately 1,000 acres and includes a modern military airport. In addition to the property at Middle River, the Company leases in the Baltimore area approximately 284,000 square feet of space for office and storage purpose. A new Corporate Administrative Headquarters is presently being constructed at Baltimore Friendship International Airport. The building will contain approximately 80,000 square feet.

The Company in 1955 acquired by purchase approximately 3,860 acres of land near Denver, Colorado, which has been improved by the construction of administration, engineering and manufacturing

buildings containing in the aggregate approximately 1,396,000 square feet. The Company leases approximately 2,500 acres of land adjacent to the Denver plant site and also for its activities in the Denver area, office and storage space containing approximately 540,000 square feet. Some 140,000 square feet of government-owned space is used by the Company in the Denver area.

The Company acquired in 1956 by purchase approximately 6,770 acres of land near Orlando, Florida for use of the Orlando Division in the production of guided missiles and electronics. A fully integrated plant containing approximately 760,000 square feet has been completed at this location. In addition to the property owned by the Company, the Orlando Division utilizes for office and storage purposes leased areas containing approximately 371,000 square feet.

Leased offices are maintained at Cocoa Beach, Florida for the Cocoa Division, and at Boston, Massachusetts; Chicago, Illinois; Cleveland and Dayton, Ohio; Los Angeles, California; New York City; Honolulu, Hawaii; Washington, D. C.; Hampton, Virginia; Huntsville, Alabama; Red Bank, New Jersey; Omaha, Nebraska; Rome, New York, and Wiesbaden, Germany, for representatives of the Company in those areas. The Company also leases facilities at Quehanna, Pennsylvania, for the use of its Nuclear Division.

During the five years ended December 31, 1960 the Company and its subsidiaries made gross property additions of $76,492,905 and property retirements aggregating $6,037,814.

Substantially all of the above buildings are of modern fireproof construction and have been maintained in good operating condition.

The Company knows of no material defects in title to any material portions of the properties owned by it nor of any material encumbrances thereon. No special examinations of title to properties have been made in connection with this offering.

CAPITALIZATION

The capitalization of the Constituent Companies (Martin as of June 30, 1961, American-Marietta as of May 31, 1961) and pro-forma of the Consolidated Company based on the combination of the foregoing is as follows:

	(In Thousands)		
	Martin	American-Marietta	Consolidated Company
Long Term Debt (exclusive of amounts payable within one year)			
Unsecured notes held by financial institutions		$ 67,930(1)	$ 67,930
5½% Sinking Fund Debentures due November 1, 1968 held by the public	$ 15,500(2)		15,500
Other		956	956
Preferred Stock			
5% Cumulative, $100 par value, 200,599 shares outstanding		20,060(3)	
4½% Cumulative, $100 par value, 380,000 shares outstanding			38,000(4)
Stockholders' Equity			
Common Stock, No Par value, 6,258,387 shares outstanding	3,129(5)		
Common Stock, $2 par value, 13,200,796 shares outstanding		26,402(6)	
Class "B" Common Stock, $2 par value, 3,191,189 shares outstanding		6,382(7)	
Common Stock, $1 par value, 21,336,699 shares outstanding			21,337
Additional paid-in capital	40,367	88,926	105,869
Earnings reinvested	58,322(8)	94,474(9)	151,793
	$117,318	$305,130	$401,385

NOTES:

(1) Consists of long term debt of American-Marietta, which will be assumed by the Consolidated Company. The interest rates, maturities and payments required in the next five years are shown in the Notes to American-Marietta's balance sheet in this Proxy Statement.

(2) Consists of long term debt of Martin, which will be assumed by the Consolidated Company. The sinking fund requirements are shown in the Notes to Martin's balance sheet in this proxy statement.

(3) To be redeemed prior to consolidation.

(4) The terms of the 4½% Cumulative Preferred Stock provide for an annual sinking fund of $1,150,000 and limit dividends and other payments in respect of the Common Stock to net income subsequent to November 30, 1961 plus $45,000,000.

(5) Each share to be exchanged for 1.3 shares of Common Stock, $1 par value, of the Consolidated Company.

(6) Each share to be exchanged for 1 share of Common Stock, $1 par value, of the Consolidated Company

(7) To be exchanged for 380,000 shares 4½% Cumulative Preferred Stock, $100 par value.

(8) Under the terms of the Debenture Agreement covering the 5½% Sinking Fund Debentures, $13,707,517 of the earnings reinvested are not available for the payment of dividends.

(9) Under the terms of notes payable to financial institutions, payments which may be made for the payment of dividends (other than on preferred shares) and for the acquisition of capital shares were limited to $14,000,000.

(10) The Consolidated Company, by operation of law, will assume the obligations of Martin in respect of the warrants and options described in the Notes to Martin's balance sheet herein. The number of shares of the Consolidated Company's Common Stock covered by the warrants will be 1.3 times the number of Martin's shares now covered. The number covered by the options will be approximately 1.3 times the number now covered, with such adjustment as may be necessary to preserve the "restricted" status for purposes of the Internal Revenue Code. All figures are based on shares outstanding June 30, 1961 as to Martin and May 31, 1961 as to American-Marietta, and would be changed by exercise of options, warrants and conversion rights after those dates.

PRO FORMA COMBINED SUMMARY BALANCE SHEET
(Giving effect to the proposed consolidation of The Martin Company and American-Marietta Company)

The pro forma combined summary balance sheet, giving effect to the proposed consolidation of The Martin Company and American-Marietta Company on a "pooling of interests" basis, combines the balance sheet of Martin and the consolidated balance sheet of American-Marietta and consolidated subsidiaries as of the end of the first six months of each of their respective 1961 fiscal years. The pro forma balance sheet should be read in conjunction with the aforementioned separate balance sheets of Martin and American-Marietta and the related notes to the respective financial statements appearing elsewhere in this proxy statement.

	$101,818	$236,244	$(21,063)	$316,999
	$212,105	$369,263		$581,368

The pro forma adjustments give effect to the following:

1. Retirement of 5% Cumulative Preferred Shares at $105 per share prior to the consolidation, either from cash on hand and/or proceeds of short term bank loans. The retirement premium of $1,003,000 has been charged to earnings reinvested.

2. Conversion of all of the outstanding American-Marietta Class B Common Shares, $2 par value, for 380,000 new 4½% Cumulative Preferred Stock, $100 par value (aggregate par value $38,000,000), of the Consolidated Company.

3. Conversion (on the basis of 1.3 shares for 1 share) of all of the 6,258,387 outstanding shares of Martin Common Stock, without par value (aggregate stated value $3,129,193), for 8,135,-903 common shares, $1 par value of the Consolidated Company, and conversion (on a 1 for 1 basis) of all of the 13,200,796 outstanding American-Marietta Common Shares, $2 par value (aggregate par value $26,401,592), for 13,200,796 shares of Common Stock, $1 par value of the Consolidated Company. The aggregate par value, $21,336,699, of all of the 21,336,699 shares of Common Stock of the Consolidated Company to be outstanding will be $8,194,086 less than the combined aggregate of the stated value of Martin Common Stock and the par value of American-Marietta Common Shares outstanding.

4. Reduction of additional paid-in capital by $23,423,536, representing the amount by which the combined aggregate par value of the new 4½% Cumulative Preferred Stock and Common Stock of the Consolidated Company exceeds the combined aggregate par value of Martin Common Stock and American-Marietta Common and Class B Common Shares outstanding.

STATEMENTS OF EARNINGS

The Martin Company

The following statement of earnings of the Company for the five years ended December 31, 1960 has been reviewed by Touche, Ross, Bailey & Smart, independent certified public accountants, whose opinion appears elsewhere in this Proxy Statement; the information for the six-month periods ended June 30, 1960, and June 30, 1961, has not been audited. The statement of earnings should be read in conjunction with the financial statements and related notes included elsewhere in this Proxy Statement. The unaudited figures for the six months ended June 30, 1960 and June 30, 1961 include all known adjustments (consisting only of normal recurring accruals) considered necessary for a fair presentation of earnings for the respective periods.

During the period from January 1, 1956 through October 31, 1958 the Company had certain subsidiaries, the operations of which are included in the statement of earnings for the years ended December 31, 1956, 1957 and 1958. All of these subsidiaries were merged into the Company October 31, 1958.

The accompanying earnings statement for the year 1956 has been restated to give effect to the renegotiation refund described in Note A and the effect of such refund upon the federal taxes applicable to that year.

NOTES

(A) Under the Renegotiation Act of 1951, the Company has received clearance from The Renegotiation Board for 1952 and prior years and for the year 1957. The Renegotiation Board has made unilateral determinations that the Company's profits were excessive for the years 1953 to 1956. The effect of the Board's actions is summarized below:

	Excessive Profits Determined By Board	Requested Refund, Net of Federal And State Tax Credits	Liability In Accounts As Of Dec. 31, 1960 and June 30, 1961
1953	$3,500,000	$1,526,192	$ (1)
1954	6,250,000	2,816,793	2,816,793
1955	3,500,000	1,430,279	1,430,279
1956	4,796,101	2,008,316	1,146,188 (2)
			$5,393,260

(1) Year 1953 paid under protest—Company has a claim for Federal income tax refundable in the amount of $1,636,567.

(2) Amount provided for 1956 is net of a claim which was before the Armed Services Board of Contract Appeals to recover certain contract costs previously disallowed. The claim has been denied and the requested refund should be correspondingly reduced by The Renegotiation Board.

The Company believes that no excessive profits were realized for the years 1953 to 1956 and has appealed to the Tax Court for a redetermination of the Board's findings for these years. The Renegotiation Act provides that on appeal, if the Tax Court shall find excessive profits were realized, it has the power to determine that the amount of such excessive profits is less than, equal to or greater than that determined by the Board.

The earnings statement for 1956 has been restated to reflect the Board's determination in the accounts, and the federal income taxes for 1956 have been reduced by $1,241,703 to reflect the refundable federal taxes applicable to such renegotiation refund.

Sales and profits for 1958 and subsequent years are also subject to renegotiation. The Company has no basis for anticipating the final actions of The Renegotiation Board and intends to take such actions as may be required to sustain its position that no excessive profits have been realized for any year. Accordingly, no provisions have been made in the accounts for 1958 or subsequent years.

(B) The Company incurred production costs of approximately $92,000,000 to December 31, 1958 (of which $40,000,000 was incurred in the prior year) under a letter contract, originally contemplating a definitive fixed price contract. In subsequent negotiations the Company and the Government agreed that the definitive contract would be of a cost reimbursement type. Accordingly, pursuant to its regular accounting policy in accounting for contracts of this type, during 1958 sales were recorded in the amount of approximately $98,000,000 on which the net income was approximately $3,165,000 of which approximately $1,375,000 relates to costs incurred in the prior year.

(C) The caption Selling, General and Administrative Expenses has been omitted as being inapplicable since substantially all of the Company's costs and expenses are incurred in connection with production under sales contracts and accordingly have been consistently considered to be directly applicable to performance under such contracts and are, therefore, classified in the financial statements as work in process or cost of sales.

(D) Cost of sales includes provisions for Maryland and Colorado State income taxes as follows: years ended December 31, 1956, $718,500; 1957, $605,883; 1958, $717,970; 1959, $523,649; 1960, $744,906, and for the six months ended June 30, 1961, $694,900.

American-Marietta Company and Consolidated Subsidiaries

The following statements of consolidated income of American-Marietta and consolidated subsidiaries for the five (5) years and six (6) months ended May 31, 1961 include the results of operations from dates of acquisitions of companies acquired, except as to companies merged during the years 1956 to 1960 which were treated for accounting purposes as "poolings of interests", the results of operations of which have been included for all periods. In annual reports of American-Marietta to its shareholders for the years 1956 through 1959, the results of operations of these companies have been included only from the beginning of the fiscal year in which the acquisition took place; and to this extent results of operations shown herein differ from those reported in such years.

The statements reflect certain retroactive adjustments relating to earnings of foreign (except Canadian) subsidiaries and to federal income taxes and interest thereon as described in Notes A and B of Notes to Financial Statements on page 41.

The statements have been examined for the five years ended November 30, 1960, by Ernst & Ernst and other independent accountants, whose reports with respect thereto are included elsewhere in this Proxy Statement. The statements for the periods of six months ended May 31, 1960, and May 31, 1961, respectively, are unaudited, but American-Marietta Company believes that they reflect all adjustments (consisting only of normal recurring accruals) necessary to present a fair statement of the results of operations for these periods. The statements should be read in conjunction with the related consolidated financial statements of American-Marietta Company and consolidated subsidiaries and notes thereto included elsewhere in this Proxy Statement.

NOTES:

(1) Alphabetical notes refer to notes to financial statements of American-Marietta Company and consolidated subsidiaries included elsewhere in this proxy statement.

(2) Amounts deducted for dividends on Preferred Shares include an adjustment for Preferred Shares issued in connection with the acquisition of one company which for accounting purposes was treated as a "pooling of interests."

(3) For information as to dividend restrictions on Class B Common Shares and the basis upon which Class B Common Shares may be converted into Common Shares, reference is made to Note D of notes to financial statements.

(4) The annual dividend requirement on Preferred Shares outstanding at November 30, 1960, was $994,860 and at May 31, 1961, $1,002,995.

(5) Net sales and net income for the six months ended May 31, 1961, are not necessarily indicative of the results of operations which may be expected for the entire year ending November 30, 1961.

The decline in net income for the six months ended May 31, 1961, as compared to the six months ended May 31, 1960, is attributable to the deferment of building and road construction activities due to unfavorable weather in the early part of the period and to a decline in the volume of business in certain products. This decline, however, has not continued into the current quarter, and sales and net income in the months of June and July 1961, have been greater than in the corresponding months of 1960.

PRO FORMA COMBINED SUMMARY OF EARNINGS

The following pro forma combined summary of earnings has been prepared by combining amounts shown in separate statements of earnings of Martin and of American-Marietta and consolidated subsidiaries (without regard for differing fiscal periods and before deduction of dividends on preferred shares of American-Marietta) after giving effect in all periods to a 5% interest charge (net of income taxes) which would have been incurred had amounts of debt existed equal to the aggregate par value of the American-Marietta 5% Cumulative Preferred Shares then outstanding. The pro forma combined summary of earnings should be read in conjunction with the separate statements of earnings of Martin and of American-Marietta and consolidated subsidiaries and notes thereto included elsewhere in this Proxy Statement.

	(In Thousands)						
						First Six Months	
	1956	1957	1958	1959	1960	1960	1961
Sales	$603,517	$683,873	$761,930	$863,880	$1,019,335	$462,901	$565,423
Net earnings	31,341	29,270	32,485	39,181	40,802	16,368	19,609(1)
Dividend requirements on proposed 4½% Cumulative Preferred Stock of Consolidated Company	1,710	1,710	1,710	1,710	1,710	855	855
Net earnings applicable to common shares	29,631	27,560	30,775	37,471	39,092	15,513	18,754

(1) Includes extraordinary profit of $3,750,000 from sale of investment.

PER SHARE EARNINGS

The following tabulation, based on the Pro Forma Combined Summary of Earnings set forth above, compares, for the periods indicated, the net earnings per share of Common Stock of Martin and of Common and Class B Common Shares of American-Marietta and pro forma combined. The per share earnings for American-Marietta are based on the average shares outstanding during each period, after adjustment for stock splits of 5 for 4 in 1956, 3 for 2 in 1957 and 5 for 4 in 1959; shares issued in acquisition of companies treated for accounting purposes as "poolings of interests" have been considered outstanding from the beginning of the fiscal years of such companies in 1956. The per share earnings for Martin are based on the number of shares outstanding at the end of the respective periods (changes during the periods are not considered to be material), after adjustment for stock dividends of 5% in 1956 and 1959, and stock split of 2 for 1 in 1961. The per share earnings, pro forma, repre-

sent the earnings for each period which would have been allocable to each share of Martin and American-Marietta respectively had the consolidation become effective at the beginning of the fiscal year 1956.

	The Martin Company		American-Marietta Company	
	Before Consolidation	Pro Forma (Based on 1.3 for 1 Conversion)	Before Consolidation Applicable to Common and Class B Common	Pro Forma (Based on 1 for 1 Conversion of Common)
1956	$1.59	$2.09	$1.54	$1.61
1957	1.61	1.90	1.33	1.46
1958	1.91	2.03	1.34	1.56
1959	2.17	2.38	1.61	1.83
1960	2.71	2.43	1.46	1.87
First six months:				
1960	1.24	.98	.54	.75
1961	1.56(1)	.92(1)(2)	.36(2)	.71(1)(2)

(1) Exclusive of extraordinary profit of $3,750,000 from sale of investment equivalent to $.60 per share of Martin before consolidation, and $.23 per share of Martin and $.18 per share of American-Marietta on the pro forma basis.

(2) Per share earnings for the six months ended May 31, 1961, are not necessarily indicative of the results of operations which may be expected for the entire year ending November 30, 1961. The decline in per share earnings for the six months ended May 31, 1961, as compared to the six months ended May 31, 1960, is attributable to the deferment of building and road construction activities due to unfavorable weather conditions prevailing in the early part of the period and to a decline in the volume of business in certain products.

BOOK VALUE OF COMMON STOCKS

There is set forth below a comparison of book values per share of Common Stock of Martin at June 30, 1961 with Common Shares (including Class B) of American-Marietta as of May 31, 1961 and pro-forma for the Consolidated Company.

	Martin June 30, 1961	American-Marietta May 31, 1961	Consolidated Company (Pro-forma)
Common stock equity	$101,817,926	$216,184,171	$278,999,097
Shares of Common Stock outstanding at end of period	6,258,387	16,391,985	21,336,699
Book value per share of Common stock	$16.27	$13.19	$13.08
Book value per share of Martin common stock based on exchange ratio of 1.3 to 1			$17.00

PRICE RANGE OF COMMON STOCKS

The Common Stock of Martin is listed on the New York, Philadelphia-Baltimore and Pacific Coast Stock Exchanges and it is anticipated that the Common Stock of the Consolidated Company will be similarly listed. The Common Shares of American-Marietta are traded in the Over-the-Counter Markets in New York and Chicago and other financial centers. The high and low sale prices of the Common Stock of Martin on the New York Stock Exchange by quarterly periods during the two years 1959 and 1960, and the six months ended June 30, 1961, and on June 30, 1961, are shown below. Market quotations on the Martin Common Stock are reported on the basis of the published closing sale prices on the New York Stock Exchange; whereas quotations on the American-Marietta Common Shares for the

same periods are reported on the basis of bid and asked prices as reported by the National Quotation Bureau, Incorporated of New York City, as follows:

	Martin (1)		American-Marietta (2)			
			Bid		Asked	
Quarter ended	Low	High	Low	High	Low	High
March 31, 1959	$16.19	$22.69	$32.00	$44.00	$32.20	$44.20
June 30, 1959	21.31	31.38	41.20	46.40	41.60	46.80
September 30, 1959	17.69	26.75	37.25	44.00	37.50	44.50
December 31, 1959	19.00	25.38	37.63	42.00	37.75	42.25
March 31, 1960	18.63	22.13	34.00	38.38	34.13	38.50
June 30, 1960	18.00	24.43	31.75	36.50	32.00	36.75
September 30, 1960	22.56	29.31	28.75	34.38	29.00	34.50
December 31, 1960	24.13	32.69	27.63	34.13	27.88	34.25
March 31, 1961	29.31	37.88	30.88	40.50	31.00	40.75
June 30, 1961	30.50	39.00	29.00	37.00	29.75	37.13
On August 15, 1961	35.63	36.50	30.13	30.38	30.50	31.00

(1) Adjusted to reflect the two-for-one split effected on February 10, 1961, for stockholders of record January 20, 1961.

(2) Adjusted to reflect five-for-four split in July, 1959.

The Class B Common Shares of American-Marietta are not listed on any exchange, and there has been no trading in such shares.

DIVIDENDS

The constituent companies since December 21, 1960 as to Martin and February 1, 1960 as to American-Marietta have paid quarterly cash dividends on their respective Common Stocks at the annual rate of $1 per share. Subject to future business conditions and the financial condition of the Consolidated Company which may change from time to time, the managements contemplate the continuance of quarterly dividends on the Common Stock of the Consolidated Company at the same rate.

A summary of cash dividends paid per share, adjusted for stock dividends and splits, is presented below:

	The Martin Company	American-Marietta Company
1956	$ .73	$ .58
1957	.76	.68
1958	.76	.80
1959	.76	.85
1960	.85	1.00
First six months:		
1960	.40	.50
1961	.50	.50

MANAGEMENT

Directors

When the consolidation becomes effective, the Board of Directors of the Consolidated Company will consist of eighteen members, nine of whom are present Directors of Martin and nine of whom have been designated by the Board of Directors of American-Marietta.

The following information is presented in respect of the Martin Directors who will become Directors of the Consolidated Company* and will serve as such until the annual meeting in April, 1962:

Name	Principal occupation for last five years	Martin Director Since	Shares of Martin Common Stock beneficially owned August 4, 1961
George M. Bunker	Chairman of the Board and Chief Executive Officer of The Martin Company	1952	186,490
William B. Bergen	Executive Officer of The Martin Company	1958	23,418
William A. Burns	President and Director, Trailmobile, Inc. (Manufacturers truck-trailers)	1957	420
Clarence W. Miles	General Counsel of The Martin Company and Partner of Miles & Stockbridge (Attorneys)	1958	20,265
John E. Parker	Independent Business Consultant	1956	4,000
Everett H. Pixley	Vice President, Mellon National Bank and Trust Company (Banking)	1949	256
Alexander B. Royce	Partner of Chadbourne, Park, Whiteside & Wolff (Attorneys)	1953	508
Duncan M. Spencer	Chairman of the Board and Executive Officer, Fiduciary Trust Company of New York (Banking)	1952	1,000
John L. Sullivan	Partner of Sullivan, Shea & Kenney and of Sullivan & Wynot (Attorneys)	1952	20,004

* Mr. Frank F. Russell, a director of Martin for many years, was unable to accept a place on the Board of Directors of the Consolidated Company due to the fact that he is a director of another corporation whose business is competitive in certain respects with that of the Consolidated Company.

The following information is presented in respect of the American-Marietta Directors and officers who will become Directors of the new company and will serve as such until the annual meeting in April, 1962:

Name	Principal occupation for last five years	American-Marietta Director Since	American-Marietta Shares beneficially owned July 20, 1961 (1)	
			Common	Class B
Grover M. Hermann	Chairman of the Board of American-Marietta Company	1930	11,671	2,445,650
Robert E. Pflaumer	President of American-Marietta	1954	15,826	70,314
Harry N. Huntzicker	Executive Vice President of American-Marietta, previously Vice President of United States Gypsum Company	1961	600	
William J. Cabaniss	President of Southern Cement Company, now a division of American-Marietta	1956	30,000	
John F. Donoho	Financial Vice President of American-Marietta	——	1,365	
Leigh R. Gignilliat, Jr.	Vice President of American National Bank & Trust Company of Chicago	1953	1,272	
J. Clifford Knochel	Vice President of American-Marietta, previously Vice President of Devoe & Reynolds, Inc.	1959	1,701	
Ray L. Oughton	Director and Vice Chairman of the Board of American-Marietta until his voluntary resignation April 18, 1961, and since then Divisional President of the Madison Silo Division of American-Marietta.	1934	5,372	
W. Trent Ragland	President of Superior Stone Company, now a division of American-Marietta	1960	87,535	

(1) Except as otherwise indicated, includes shares owned by trusts in which the person named has an interest, but does not include shares owned by members of the family of the person named in which such person has no interest.

(2) Does not include Common Shares and Class B Common Shares owned by trusts for members of Mr. Hermann's family in which Mr. Hermann has no beneficial interest and by a charitable foundation which was created by him.

(3) Before the consolidation becomes effective, Mr. Pflaumer expects to convert his Class B Common Shares into Common Shares. After the consolidation becomes effective, Mr. Pflaumer will have an option to purchase 19,125 shares of Common Stock of the Consolidated Company from certain other stockholders.

Holders of Class B Common Shares of American-Marietta as of July 20, 1961

Beneficial owner	Number of Shares
American National Bank and Trust Company, et al. Trustees for benefit of Shirley Hermann	311,275
American National Bank and Trust Company, et al. Trustees for benefit of Robert Hermann	340,061
Grover M. Hermann	2,445,650
Grover M. Hermann Foundation	11,720
Robert Hermann	12,169
Robert Pflaumer	70,314
Total	3,191,189

Election of Officers of Consolidated Company

It is presently intended that the directors named above will meet promptly after the consolidation becomes effective and will elect the following executive officers:

George M. Bunker, President and Chief Executive Officer
Grover M. Hermann, Chairman of the Board
William B. Bergen, Vice-President
Robert E. Pflaumer, Vice-President
John F. Donoho, Financial Vice-President and Treasurer
William L. Lucas, Secretary

At the same time it is intended that Clarence W. Miles will be designated as General Counsel of the Consolidated Company.

Remuneration of Directors and Officers

The following table shows certain information with respect to remuneration paid by Martin to its officers and Directors during the year 1960:

Name of individual or identity of group and capacity in which remuneration was received	Aggregate remuneration	Premium paid by Martin under Employees' Pension Fund Plan (1)
George M. Bunker, Chairman of the Board	$150,000(2)	$16,009
William B. Bergen, President and Director	100,000	9,209
Clarence W. Miles, General Counsel and Director	80,000(3)	None
George T. Willey, Vice President	57,000	9,872
All officers and directors as a group (including above) ..	848,001(4)	68,901

(1) The annual benefit estimated to be payable under the Employees' Pension Plan upon retirement at normal retirement age for George M. Bunker and William B. Bergen is $25,000 and for George T. Willey is $13,377. Clarence W. Miles is not eligible under the Plan.

(2) As of April 1, 1959, the Company entered into a five-year contract with George M. Bunker. Under the terms of the contract Mr. Bunker will devote substantially his entire business time as chief executive and general manager of the Company at an annual salary of $120,000 subject to such increases and additional payments as may be determined by the Board of Directors. If he should be permanently disabled or die during the term of the contract the compensation provided thereby shall be continued for a period of six months.

(3) On October 1, 1960 the Company entered into an employment agreement with Clarence W. Miles by which Mr. Miles agreed to serve as General Counsel for a term of 10 years at an annual salary of not less than $80,000. Either party has the right to terminate the agreement after the expiration of 5 years in which event it is agreed that Mr. Miles shall serve in a consulting capacity at an annual salary of $30,000. In the event that Mr. Miles shall be permanently disabled the Company may terminate the agreement and thereupon the Company shall be obligated to pay the compensation as General Counsel to Mr. Miles for a period of 6 months or in the event of his death during the 6 months period to his widow or his estate.

(4) Does not include $40,900 paid for legal services to Sullivan, Shea & Kenney, of which firm John L. Sullivan, a Director, is a partner; or $32,142 paid for legal services to Miles & Stockbridge, of which firm Clarence W. Miles is a partner.

The following table shows certain information with respect to remuneration paid by American-Marietta to certain of its officers and Directors who will become Directors of the Consolidated Company, during the fiscal year ended November 30, 1960:

Name	Title	Salaries and Fees	Bonuses	Pension, Profit Sharing and Retirement Benefits: Accrued for Year 1960	Pension, Profit Sharing and Retirement Benefits: Estimated Annual Benefits
Grover M. Hermann	Chairman of Board of Directors	$ 98,333	$ —	—	$ 6,000(1)(2)
Robert E. Pflaumer	President and Director	80,000	40,000	$ 3,917	22,064(1)
William J. Cabaniss	Divisional General Manager and Director	36,000	—	1,718	5,220(1)
John F. Donoho	Financial Vice President	40,000	10,000	—	—
J. Clifford Knochel	Vice President and Director	45,000	5,000	2,168	7,008(1)
All Directors and Officers	Directors and Officers	1,108,503	333,210		

(1) Including benefits from contributions by participants under Company's Salaried Employees' Retirement Plan.
(2) Maximum vested benefits under Company's Salaried Employees' Retirement Plan.

Stock Options of Martin

During the period from January 1, 1960 to August 4, 1961, (i) Mr. Bunker exercised options to purchase 42,000 shares (representing all of his then remaining unexercised options) at $15.89 per share, the closing market value on the date of exercise being $36.63; (ii) Mr. Bergen exercised options to purchase 9,260 shares at $12.15 per share, the market value on the date of exercise being $26.88; (iii) Mr. Miles exercised options to purchase 12,600 shares at $15.89 per share and 7,665 shares (representing all of his then remaining unexercised options), at $19.52 per share, the market value per share on the dates of exercise ranging from $27.88 to $36.63; and (iv) Mr. Willey exercised options to purchase 2,100 shares at $15.89 per share, the market value on the date of exercise being $32.31 per share.

During the same period all officers and directors of Martin as a group, including those previously set forth in detail, exercised options as follows:

Quarter or Period Ended	Shares	Option Price	Market Price on Date Purchased
Sept. 30, 1960	19,032	$12.15—15.89	$26.88—28.13
Dec. 31, 1960	21,000	15.89—19.52	25.94—31.44
Mar. 31 1961	2,100	15.89	32.31
June 30, 1961	14,700	15.89	37.50—38.00
Aug. 4, 1961	45,465	15.89—19.52	36.63
	102,297		

During the same period options expiring April 30, 1968 to purchase 6,000 shares at $19.38 per share and 16,000 shares at $23.13 per share were granted to all officers and directors as a group, the price per share being the market price on the date options were granted.

During February 1961 Mr. Willey sold 1,000 shares of Martin Common Stock, the net proceeds of which sale amounted to $34,555.42. This sale was within less than 6 months of the date when he exercised an option to purchase 1,050 shares (2,100 shares after giving effect to the 2 for 1 stock split effected on February 10, 1961 for stockholders of record January 20, 1961) and under the provisions of Section 16(b) of the Securities Exchange Act of 1934 any profit realized from such sale inures to and is recoverable by the Company. Based on the provisions of Rule X 16B-6 of the Securities and Exchange Commission the profit on the sale amounted to $10,119.82. Appropriate steps are being taken by the Company to recover the short term profit.

The number of shares issued and the price per share have been adjusted for stock dividends subsequent to the issuance of the respective stock options.

Subsequent to June 30, 1961, Martin has granted options or agreed to grant options to 2 employees other than officers and directors, to purchase in the aggregate 10,000 shares of its Common Stock at the closing market price on the date of the grant. After the effective date of the consolidation no further options will be granted under the Stock Option Plans of Martin. No shares of Common Stock will be reserved by the Consolidated Company for issuance upon options in lieu of the 19,000 shares of Common Stock of Martin which were still reserved for the granting of options when its plans terminate on the effective date of the consolidation.

All of the foregoing transactions reflect the 2-for-1 stock split effected on February 10, 1961, for stockholders of record January 20, 1961.

DESCRIPTION OF COMMON STOCK OF MARTIN

The only class of capital stock of Martin authorized and outstanding is the Common Stock without par value which has exclusive voting rights. The holders of Common Stock are entitled to receive such dividends as are declared by the Board of Directors out of any funds of Martin legally available therefor and are entitled to share pro rata in the distributable assets of Martin in the event of any liquidation, dissolution or winding up of Martin. Martin may not declare any dividend or make any distribution on its shares of stock for value, or permit a Subsidiary to purchase, redeem or otherwise acquire or retire for value any shares of stock of Martin, if upon giving effect thereto the aggregate amount expended for such purposes subsequent to December 31, 1957, shall exceed the sum of (a) the accumulated consolidated earnings (or deficit) of Martin and its Subsidiaries earned subsequent

to December 31, 1957 (without taking into consideration any net refunds made by Martin under the Renegotiation Act of 1951, for periods prior to 1958), (b) the aggregate net consideration realized from the sale after December 31, 1957, of stock of Martin, (c) the aggregate net consideration realized from the sale after December 31, 1957, of any indebtedness of Martin which has been converted into shares of stock of Martin subsequent to December 31, 1957, and (d) the sum of $5,000,000. Each holder of Common Stock is entitled to one vote for each share of stock outstanding in his name. Without assent or other action of the stockholders, the Board of Directors may from time to time receive subscriptions for or sell any or all of the then unissued shares of Common Stock, whether the same be any of the originally authorized shares or any increase thereof, and shall be under no obligation to offer the same to existing stockholders. In the opinion of Counsel for Martin, the presently outstanding shares of Common Stock are, and the shares to be issued on exercise of the Warrants to purchase shares of Common Stock issued November 1, 1958, will upon compliance with the terms of the Warrants be fully paid and nonassessable.

DESCRIPTION OF COMMON SHARES AND CLASS B COMMON SHARES OF AMERICAN-MARIETTA

Certain provisions applicable to the Common Shares and the Class B Common Shares of American-Marietta are hereafter summarized. Such summary does not contain all of the terms and provisions applicable to said shares and no summary and no effect is given as to the provisions applicable to the 5% Cumulative Preferred Shares because those shares will be redeemed prior to the special meeting of stockholders of American-Marietta.

Dividends

Dividends may be paid on Common Shares and Class B Common Shares out of any funds legally available for such purpose when and as declared by the Board of Directors, except that no dividends may be declared or paid on Class B Common Shares in any year unless an equal amount plus $2 is paid for that year on the Common Shares, and except that any dividend or distribution on the Common Shares in Common Shares or on the Class B Common Shares in Class B Common Shares may be made only so long as there is no greater proportionate increase in the number of Class B Common Shares outstanding than in the Common Shares outstanding as a result of such dividend or distribution.

The terms of the Unsecured Notes referred to under the caption "Capitalization" of American-Marietta payable to insurance companies set forth certain minimum requirements as to consolidated working capital and restrict the payment of cash dividends and purchases or other retirements of Capital Shares. In this connection, reference is made to Note "C" to Financial Statements.

Voting Rights

The holder of each outstanding share regardless of class is entitled to one vote for each share held on each matter submitted to a vote at a meeting of shareholders and may cumulate votes for the election of directors.

Liquidation Rights

In the event of any dissolution, liquidation or winding up, the remaining assets of the Company shall be distributed to the holders of the Common Shares of both classes, without preference between the holders of the Common Shares and Class B Common Shares. Neither a merger nor consolidation of the Company with or into any other corporation, nor a reorganization, nor a purchase or redemption of all or a part of the outstanding shares of any class, nor the sale of the property and business of the Company substantially as an entirety, shall be considered a liquidation or winding up of the Company.

Preemptive Rights

No holder of any shares of any class of the Company has any right, as such holder, to purchase or otherwise acquire any shares of any class of the Company, now or hereafter authorized, of any se-

curities convertible into any such shares, or warrants or other instruments to subscribe for or otherwise acquire any such share, whether the same be unissued or issued and thereafter acquired by the Company.

Conversion Rights

Under the Articles of Incorporation of the Company, the Class B Common Shares are convertible, subject to the restrictions of such conversion set forth in the Articles of Incorporation, into Common Shares on a share for share basis. The conversion rights of certain of these shares are further restricted by an Agreement dated November 1, 1958, between Grover M. Hermann, Shirley Hermann and Robert Hermann. At this date 340,523 Class B Common Shares are eligible for conversion and the remaining shares are subject to the conversion restrictions of the Agreement and may not be converted until they become eligible for conversion thereunder as follows: 62,500 shares on each January 1 and July 1 to and including July 1, 1969. The conversion restrictions terminate completely on January 1, 1970. The agreement provides that the shares eligible for conversion thereunder shall be proportionately increased in the event of stock dividends, stock splits or other increases in the outstanding Class B Common Shares; that the restrictions of the Agreement shall continue in effect with respect to the shares subject thereto irrespective of any transfers of shares by the original parties; and that the Agreement shall be irrevocable except that it may be amended or terminated with the consent of the holders of not less than ⅔ of the outstanding Class B Common Shares, as a class, and of the holders of not less than ⅔ of the outstanding Common Shares, as a class.

The Agreement further provides that if, as a result of certain mergers or consolidations or acquisitions of assets, the persons who were the shareholders of the Company immediately prior to any such transaction shall not be or become the holders of shares representing at least 60% of the voting power of all shares, and at least 50% of each class of shares (other than Preferred Shares, as defined) of the Company, or of the acquiring or surviving corporation, outstanding immediately after, or issuable as a part of, such transaction, the conversion restrictions imposed by the Agreement may be modified or terminated by the holder or holders of not less than 60% of the then outstanding Class B Common Shares subject to the Agreement.

DESCRIPTION OF STOCK OF CONSOLIDATED COMPANY

Dividends

After cumulative dividends have been paid at the rate of 4½% on the Preferred Stock, dividends may be paid on the Common Stock, when and as declared by the Board of Directors and subject to the limitations provided in the terms of the Preferred Stock and the 5½% Sinking Fund Debentures and in A-M's long term notes. See footnotes to Capitalization of Consolidated Company and to Financial Statements of the Constituent Companies in this Proxy Statement.

Voting Rights

The holders of Common Stock will be entitled to one vote per share, but will not have cumulative voting rights. The holders of Preferred Stock will have no voting rights except as specifically provided by law and except that in the event of default in payment of dividends on the Preferred Stock in an amount equal to four quarterly dividends or in the event of a default in the Sinking Fund provided for the Preferred Stock, the Preferred Stock will have the right to elect one-third of the board of directors.

Liquidation Rights

After payment to the Preferred Stock of $100 per share plus accrued dividends plus $5 per share if the liquidation is voluntary, the Common Stock will be entitled to all remaining assets of the Company properly distributable to stockholders upon any liquidation of the Consolidated Company.

Miscellaneous

The Preferred Stock is subject to redemption as a whole, but not in part, at any time after October 1, 1964, at $105 per share plus accrued dividends. The Preferred Stock is entitled to a sinking fund as set forth under "Capitalization of the Consolidated Company". The Company may not change its stock provisions in certain respects adverse to the Preferred Stock or issue or sell any additional Preferred Stock or stock ranking prior thereto or on a parity therewith without the consent of the holders of two-thirds of the Preferred Stock. There are no preemptive rights.

Reference is made to the stock terms of the Consolidated Company set forth in full in the Articles included in Appendix A.

TAX CONSEQUENCES

In the opinion of counsel for the constituent companies the consolidation will not result in taxable gain to either of the constituent companies and stockholders of the constituent companies will not realize any taxable gain or deductible loss as a result of the conversion of their stock into stock of the Consolidated Company. Gain or loss will be recognized to stockholders who may dissent and receive in cash the value of their stock in appraisal proceedings, and gain, if any, will be recognized to stockholders of Martin with respect to the proceeds of sale of any fractional share interest, but not in excess of the amount received upon such sale.

RIGHTS OF DISSENTING STOCKHOLDERS

Stockholders of Martin who object to the consolidation have such rights as objecting stockholders in respect of the proposed consolidation as are provided by Section 73 of Article 23 of the Annotated Code of Maryland (1957 Edition). Under this Section, objecting stockholders shall be entitled to demand and receive payment of the amount equal to the fair value of their stock. If such stockholders (1) shall prior to, or at, the special meeting of stockholders, file with Martin objection in writing to the proposed consolidation; (2) shall not vote in favor of the consolidation; (3) shall within twenty days after the Articles of Consolidation and Plan have been accepted for record by the Department of Assessments and Taxation of Maryland, make upon the Consolidated Company written demand for payment for his stock, stating the number and class of shares for which payment is demanded. Any stockholder, who fails to comply with the requirements of this Section within the time specified, shall be bound by the terms of the consolidation, merger or transfer. Merely voting against, or a direction in a proxy to vote against, the adoption of the Articles of Consolidation and Plan will not comply with the conditions required of objecting stockholders by Section 73 of Article 23 of the Annotated Code of Maryland (1957 Edition).

The Consolidated Company must deliver or mail to each objecting stockholder written notice of the date of acceptance for record of the Articles of Consolidation and Plan by the Department of Assessments and Taxation of Maryland, and may also deliver or mail to each such stockholder a written offer to pay for his stock at a price deemed to be the fair value thereof.

Within fifty days after the acceptance of the Articles of Consolidation and Plan for record by the Department of Assessments and Taxation of Maryland, either the Consolidated Company or any objecting stockholder who has not received payment for his stock may petition a court of equity in the City of Baltimore to determine the fair value of such stock. If such court finds that any objecting stockholder is entitled to have the value of the stock determined, it shall appoint three disinterested appraisers to determine the fair value of such stock. Such value shall be determined as of the close of business on the day of the stockholder's vote on the Articles of Consolidation and Plan to which objection was made, excluding any appreciation or depreciation, directly or indirectly, consequent upon such action or the proposal thereof. The appraisers are required to file a written report of their findings as to the fair value of the stock of the objecting stockholder, and the statute provides for appropriate action to be taken by the court in relation to such report of the appraisers.

The costs of valuation proceedings, which will include the costs of making the appraisal, are determined by the Court and will be assessed against the Consolidated Company; provided, that all or any part of the costs may be apportioned and assessed as the Court deems equitable against any or

all of the objecting stockholders parties to the proceedings, if, taking into consideration the price which the Consolidated Company offered for such stock, the financial statements and other information furnished, and such other circumstances as the Court deems relevant, the Court finds that the action of the stockholders, in failing to accept the offer was arbitrary and vexatious or not in good faith.

OTHER MATTERS

Vote needed to approve Proposed Consolidation

The affirmative vote of a majority of the outstanding shares is required to authorize the proposed consolidation.

Voting Rights

As of the close of business on July 31, 1961, Martin had outstanding 6,257,739 full shares of Common Stock and Scrip Certificates for 10,901 tenths of a share. Shareholders are entitled to one vote for each full share registered in their names. There are no classes of stock of Martin other than Common Stock. Shareholders of record at the close of business on August 30, 1961, the record date fixed by the Board of Directors, will be entitled to vote at the meeting.

Miscellaneous

The Management knows of no business constituting a proper subject for action by the stockholders which will be presented for consideration at the meeting other than that shown above.

The proxies are solicited by the Management of Martin and the cost of such solicitation has been or will be paid by Martin. In addition to solicitation by mail, arrangements may be made with brokerage houses and other custodians, nominees, and fiduciaries to send proxy material to their principals, and Martin may reimburse them for their expense in so doing. Martin has retained Georgeson and Company of New York City to aid in the solicitation of proxies at a cost estimated to be about $3,000. To the extent necessary in order to assure sufficient representation, officers and regular employees of Martin may request the return of proxies personally, by telephone or telegram. The extent to which this will be necessary depends entirely upon how promptly proxies are received, and stockholders are urged to send in their proxies without delay.

Any proxy given pursuant to this solicitation may be revoked by the person giving it at any time before its exercise. The shares of Martin's outstanding Common Stock represented by each proxy received before the Special Meeting and not revoked will be voted in favor of the proposed Consolidation Agreement and Plan set forth in the accompanying Notice of Special Meeting of Stockholders and in this statement, unless the proxies are instructed in the proxy to do otherwise.

W. L. Lucas, *Secretary*

August 30, 1961

IMPORTANT

TO INSURE REPRESENTATION AT THE SPECIAL MEETING, STOCKHOLDERS ARE REQUESTED TO SIGN AND MAIL PROMPTLY THE ACCOMPANYING PROXY FOR WHICH A RETURN ENVELOPE IS PROVIDED. NO POSTAGE IS REQUIRED IF MAILED IN THE UNITED STATES. IF YOU DO ATTEND THE MEETING, YOU MAY VOTE THERE IN PERSON SHOULD YOU SO DESIRE.

OPINION OF INDEPENDENT CERTIFIED PUBLIC ACCOUNTANTS

Board of Directors,
The Martin Company,
Baltimore, Maryland

We have examined the balance sheet of The Martin Company as of December 31, 1960, and the related statements of earnings, additional paid-in capital and earnings reinvested for the five years then ended. Our examination was made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances; although we were unable to obtain satisfactory confirmation of accounts receivable from the Government, we satisfied ourselves as to these accounts by other means.

In our opinion, subject to such adjustments (which neither we nor the Company are able to evaluate) as may be required as a result of renegotiation as described in Note A, the accompanying balance sheet and statements of earnings (set forth in the Proxy Statement under the heading "Statement of Earnings"), additional paid-in capital and earnings reinvested present fairly the financial position of The Martin Company at December 31, 1960, and the results of its operations for the five years then ended, in conformity with generally accepted accounting principles applied on a consistent basis.

THE MARTIN COMPANY

NOTES TO FINANCIAL STATEMENTS

(A) Renegotiation:

See Note (A) to Statement of Earnings included elsewhere in this Proxy Statement.

(B) Inventories:

Title to inventories in the amount of approximately $7,600,000 at June 30, 1961 and $8,100,000 at December 31, 1960 had passed to the United States Government as consideration for progress payments. Material, labor and other costs incurred on contracts in progress less estimated costs applied to deliveries, not in excess of realizable value, used in determining cost of sales for each of the six years ended December 31, 1960 were, respectively, $82,524,902; $55,610,080; $39,168,843; $43,060,212; $36,374,520; $15,207,678 and for the six months ended June 30, 1961, $15,978,344.

(C) Debentures:

Sinking fund provisions of the Debentures require annual redemptions of $2,250,000. Among other restrictions under the Debenture Agreement, $14,514,499 of the earnings reinvested at December 31, 1960 and $13,707,517 of the earnings reinvested at June 30, 1961 were not available for the payment of dividends.

(D) Shares of capital stock were reserved for issuance as follows:

	12/31/60	6/30/61
(a) At a price of $7.47 per share at December 31, 1960 and $3.74 at June 30, 1961 upon presentation of capital stock purchase warrants expiring April 10, 1962, issued in connection with the sale of Ten-Year 4% Convertible Subordinated Notes	6	12
(b) Upon exercise at $40.00 per unit (consisting of 1.05 shares at December 31, 1960 and 2.10 shares at June 30, 1961) to and including November 1, 1963, and at $45.00 per unit thereafter to and including November 1, 1968, of warrants issued in connection with the Company's 5½% Sinking Fund Debentures	210,000	409,435
(c) Under a restricted stock option plan for officers and other key employees	134,792	232,199
Total	344,798	641,646

(E) Stock Options

In 1952 and 1958 stock option plans for officers and key employees were approved by the stockholders providing for the granting of options to purchase 200,000 and 140,000 shares respectively of the Company's capital stock. The plans provided that the number of shares and the issue price were subject to adjustments as might be necessary to protect the optionee against dilution. Accordingly, because of stock dividends declared and a 2 for 1 stock split subsequent to granting of options, the total number of shares subject to option under the 1952 plan was increased to 225,930 and under the 1958 plan to 265,680, and the effect of such adjustments is reflected in the information presented below. The option price under both plans is the closing price of the Company's stock on the New York Stock Exchange on the day when the particular option is granted; options may not expire more than ten years from the date of grant, nor may they be exercised in less than one year from the date of grant under the 1952 plan nor two years under the 1958 plan.

The number of shares with respect to which options under the plans were granted through June 30, 1961 and the years that such options became or will become exercisable, are as follows:

Date of Grant	Date Exercisable	Number of Shares	Option Price Per Share	Option Price Total	Market Quotations at Date Exercisable Per Share	Market Quotations at Date Exercisable Total
1952	1954–1957	95,877	$ 8.04– 9.75	$ 828,750	$18.63–43.50	$3,412,868
1952	1953	75,675	9.66–10.63	799,531	13.75	1,034,687
1953	1954	18,300	11.03–13.38	215,469	24.88–28.63	418,281
1955	1956	18,048	12.15–28.13	360,000	34.00	456,960
1957	1958	16,030	18.69–39.25	387,113	32.13–33.25	318,419
1958	1960	154,980	15.89–33.10	2,838,375	44.25–56.88	3,973,331
1959	1961	14,700	18.39–46.91	317,500		
1960	1962	64,000	19.00–56.63	1,400,625		
1961	1963	10,000	32.62–38.00	357,750		
		467,610		$7,505,113		

Since inception of the plans through June 30, 1961, options under the plans were exercised as follows:

Year Exercised	Number of Shares	Option Price Per Share	Option Price Total	Market Quotations at the various dates Options were Exercised Per Share	Market Quotations at the various dates Options were Exercised Total
1953	1,350	$10.63	$ 14,344	$14.63–15.88	$ 19,869
1954	89,650	$ 9.75–13.38	951,281	19.38–33.00	2,389,868
1955	16,500	8.86–12.16	152,688	28.13–38.38	486,613
1956	62,948	8.44–11.58	547,688	40.88–43.13	2,578,197
1957	18,742	8.04–25.51	178,438	42.38–46.63	831,457
1958	2,094	11.03–25.51	35,875	31.75–33.25	69,157
1959	4,116	25.51–39.25	129,156	42.75–59.75	219,766
1960	29,985	24.30–39.05	914,700	38.75–63.88	1,681,382
1961	34,026	12.12–31.79	605,738	31.63–65.25	1,342,702
	259,411		$3,529,908		$9,619,011

At June 30, 1961, options not yet exercised under the plans were as follows:

Date of Grant	Date Exercisable	Number of Shares	Option Price Per Share	Option Price Total	Market Quotations at Date of Grant Per Share	Market Quotations at Date of Grant Total
1955	1956	4,524	$12.12	$ 54,844	$12.12	$ 54,844
1957	1958	10,815	$18.69–19.52	205,024	$18.69–19.52	205,024
1958	1960	108,360	15.89–16.55	1,722,837	15.89–16.55	1,722,837
1959	1961	10,500	19.82–23.45	234,125	19.82–23.45	234,125
1960	1962	64,000	19.00–28.31	1,400,625	19.00–28.31	1,400,625
1961	1963	10,000	32.63–38.00	357,750	32.63–38.00	357,750
		208,199		$3,975,205		$3,975,205

Capital stock issued upon exercise of options was recorded at amounts received; no charges have been reflected in income with respect to stock options. Options cancelled have been reflected by reducing the number of shares originally covered by options.

(F) On January 9, 1961 the Certificate of Incorporation was amended to change the previously authorized 6,000,000 shares of capital stock of the Company to 12,000,000 shares of common stock without par value. A 2 for 1 stock split was effected on February 10, 1961 for stockholders of record on January 20, 1961.

(G) Pensions:

A pension plan was established for employees as of July 1, 1943, providing for pension payments and death benefits through an annuity contract with a legal reserve insurance company. Effective May 1, 1951, additional pension plans were established for hourly employees providing maximum benefits, as now amended, of $67.50 per month, reduced by any retirement benefits accrued under the earlier plan. Maximum benefits under the latter plans are payable after 30 years of credited service with the Company and retirement at or after age 65. Disability benefits are likewise provided. Unfunded past service costs under the latter plans estimated to be $5,179,000 at December 31, 1960 and $8,030,000 at June 30, 1961 are being funded over a period not to exceed 30 years. The earlier pension plan has been amended so as to cover salaried employees only, providing at or after age 65 for monthly benefit payments based upon compensation and length of service. The plans are non-contributory. The aggregate cost of these plans for 1960 was $5,209,984 and it is estimated the aggregate cost of these plans for 1961 will be approximately $5,900,000. The Company has the right to discontinue these plans at any time, except that it has agreed not to change or terminate the Pension Plans for hourly paid employees prior to December 31, 1963.

(H) Property, plant and equipment:

The cost of facilities which are owned by the Company, other than those covered by certificates of necessity, is depreciated over estimated useful lives on a straight-line basis for assets acquired prior to January 1, 1954 and on a sum of the years-digits basis for assets acquired after that date, as permitted by the Internal Revenue Code.

These rates may be summarized as follows:

Class of assets	Rate of depreciation
Building and building equipment	2% to 10%
Other land improvements	4% to 11¼%
Machinery and equipment	5% to 25%
Office equipment	6⅔% to 10%
Automobiles, trucks and tractors	25%
Airplanes and boats	20% to 25%

Amortization is computed in accordance with the provisions of the Internal Revenue Code on assets covered by certificates of necessity.

Maintenance and repairs are charged to income as incurred and expenditures for major renewals and betterments are capitalized.

At the disposal or retirement of properties, the difference between the depreciated value of assets and the amount realized is charged against, or credited to, revenue.

Effective with December 31, 1953, fully depreciated property, plant and equipment was eliminated from the accounts.

(I) Supplementary profit and loss information:

	Year Ended December 31,					(Unaudited) 6 Months Ended June 30,

Royalties	729,990	94,750	—	—	—	—
	$1,853,729	$1,992,242	$2,039,383	$2,529,297	$ 3,518,589	$2,567,475

The major portion of the above charges has been charged to cost of sales. Amounts charged to other accounts were not material. There were no management or service contract fees.

ACCOUNTANTS' REPORT

Board of Directors
American-Marietta Company
Chicago, Illinois

We have examined the consolidated balance sheet of American-Marietta Company and consolidated subsidiaries as of November 30, 1960, and the related statements of consolidated income, additional capital and accumulated earnings for the period of five years then ended. Our examinations were made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances. The accounts of one company and its subsidiary for the years ended December 31, 1956, 1957, and 1958, and the accounts of another company and its subsidiaries for the years ended December 31, 1956, 1957, 1958, and 1959, were examined by other independent accountants, and the financial statements of these companies have been incorporated in the aforementioned consolidated financial statements in reliance on the reports, included elsewhere in this proxy statement, of such accountants.

In our opinion, based upon our examinations and the reports of the other accountants referred to above, the accompanying balance sheet and statements of income, additional capital and accumulated earnings present fairly the consolidated financial position of American-Marietta Company and consolidated subsidiaries at November 30, 1960, and the consolidated results of their operations for the period of five years then ended (including on a combined basis the operations of the merged companies referred to in Note A to the financial statements) in conformity with generally accepted accounting principles applied on a consistent basis.

ERNST & ERNST

(As of January 16, 1961)

ACCOUNTANTS' REPORT

Board of Directors
American-Marietta Company
Chicago, Illinois

We have examined the statements of consolidated earnings and retained earnings of Dewey Portland Cement Company and subsidiaries for the four years ended December 31, 1959. Our examination was made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances. We have not examined financial statements of the Company and subsidiaries for any period subsequent to December 31, 1959.

In our opinion, such financial statements (not shown separately herein) present fairly the results of operations of Dewey Portland Cement Company and subsidiaries for the four years ended December 31, 1959, in conformity with generally accepted accounting principles applied on a consistent basis.

PEAT, MARWICK, MITCHELL & CO.

(As of January 25, 1960)

ACCOUNTANTS' REPORT

Board of Directors
American-Marietta Company
Chicago, Illinois

We have examined the financial statements of Superior Stone Company and subsidiary for the three years ended December 31, 1958. Our examination was made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances.

In our opinion, the statements of income and accumulated earnings of Superior Stone Company and subsidiary (not shown separately herein) present fairly the results of operations of Superior Stone Company and subsidiary for the three years ended December 31, 1958, in conformity with generally accepted accounting principles applied on a basis consistent with that of the preceding year.

AMERICAN-MARIETTA COMPANY AND CONSOLIDATED SUBSIDIARIES
NOTES TO FINANCIAL STATEMENTS

Note A—Principles of Consolidation:

In accordance with the policy consistently followed, the consolidated financial statements include on a consolidated basis the accounts of the domestic and Canadian subsidiaries of American-Marietta Company.

Results of operations of companies acquired during the five years and six months covered by the statements of income have been included therein from dates of acquisition, except as to companies merged during the years 1956 to 1960 which were treated for accounting purposes as "poolings of interests," the results of operations of which have been included for all periods and the accumlated earnings accounts of which have been combined with the statements of accumulated earnings of the consolidated companies from the beginning of the periods.

The Company's equity in the underlying net assets of the consolidated subsidiaries as shown by their books exceeded the carrying amount (cost) of the Company's investments therein by $6,676,522 at November 30, 1960, and $7,458,153 at May 31, 1961. The disposition of this difference in the consolidated financial statements was as follows:

	May 31 1961	November 30 1960
Undistributed earnings of the consolidated subsidiaries since acquisition, included in "accumulated earnings used in the business"	$10,360,993	$9,626,640
Cost of investments in excess of amounts ascribed to net tangible assets acquired, included in "intangibles arising upon acquisition of companies"	2,902,840	2,950,118
	$ 7,458,153	$6,676,522

The investments in and advances to foreign (except Canadian) subsidiaries are stated at cost (November 30, 1960—$1,486,649; May 31, 1961—$1,356,938) plus the Company's equity (November 30, 1960—$1,424,994; May 31, 1961—$1,831,750) in accumulated earnings of the subsidiaries. The statements of consolidated income and accumulated earnings have been adjusted to reflect in applicable prior fiscal years the Company's equity in the earnings of the foreign subsidiaries.

Note B—Federal Income Tax:

Federal income tax returns as originally filed by the Company and subsidiaries for the fiscal years 1957 to 1959 reflected percentage depletion allowances for cement and limestone products computed generally in accordance with the principle established in the Dragon Cement Company case.

In 1960, the United States Supreme Court rendered a decision which adversely affected the Company's position with respect to the use of the liberalized percentage depletion method established in prior lower court decisions. Also, in 1960, amendments to the Internal Revenue Code were enacted, requiring a new method for taxable years beginning after December 31, 1960, and permitting taxpayers to elect to recompute percentage depletion deductions for all unsettled prior years by this method. The Company made the election and provision has been made in the accompanying financial statements for the resultant additional tax and interest thereon applicable to prior years.

Note C—Long-Term Debt:

Long-term debt consisted of the following obligations:

Notes payable to insurance companies and banks:

Interest Rate	Maturity	Amount May 31 1961	Amount November 30 1960
4⅜%	August 1, 1978	$25,000,000	$25,000,000
5½%	June 1, 1980	15,000,000	15,000,000
5½%	December 1, 1980	10,000,000	10,000,000
5⅛%	December 1, 1978	9,260,000	9,630,000
4¼%	April 15, 1964	4,500,000	4,500,000
4¾%	December 20, 1971	1,610,000	1,720,000
5¼%	June 1, 1973	1,480,000	1,605,000
4¼%	June 1, 1967	1,080,000	1,320,000
Other indebtedness		955,576	1,069,789
	TOTAL	$68,885,576	$69,844,789

Payments required in the year ending November 30, 1961 (after May 31, 1961) and in the next five fiscal years with respect to long-term debt are as follows: 1961, $1,160,635; 1962, $2,251,792; 1963, $2,926,691; 1964, $7,402,888; 1965, $2,888,952; 1966, $2,822,600.

The terms of the notes payable to insurance companies and banks set forth certain minimum requirements as to consolidated working capital and place restrictions on the payments of cash dividends (other than on Preferred Shares) and purchases or retirements of capital shares. Under the consolidated working capital requirements, the most restrictive of the debt provisions, payments which may be made in respect of cash dividends on Common Shares and for the acquisition of capital shares were limited to approximately $23,000,000 at November 30, 1960 and $14,000,000 at May 31, 1961.

Note D—Capital Shares:

No dividends may be declared or paid on any Class B Common Share in any year unless an equal amount plus $2 a share is paid for that year on the Common Shares. Dividends in excess of $2 a share may be paid on the Common Shares regardless of whether any are paid on Class B Common Shares.

Under the Articles of Incorporation, Class B Common Shares are convertible into Common Shares on a share-for-share basis, with certain limitations. However, holders of substantially all of the Class B Common Shares have entered into an agreement deferring their conversion rights so that 278,023 shares were eligible for conversion as of May 31, 1961, with not to exceed 62,500 additional shares becoming eligible for conversion during each six months cumulatively from July 1, 1961, to January 1, 1970, at which latter date the restrictions terminate.

Holders of Preferred Stock are entitled in liquidation to, and the stock is callable at, $105 a share plus dividends. Provisions of the Articles of Incorporation relating to a sinking fund for the redemption of Preferred Shares require a noncumulative annual payment equal to 3% of consolidated net income for the preceding fiscal year in excess of dividends on such shares, or, if less, 2% of the largest aggregate par value of Preferred Shares outstanding at any time prior to the close of the preceding fiscal year. A sinking fund payment of approximately $430,000 is required to be made prior to November 30, 1961. At November 30, 1960, 16,248 Preferred Shares, and at May 31, 1961, 14,621 Preferred Shares were held in the treasury by the Company, which shares may be used, in lieu of cash, to meet sinking fund requirements.

Note E—Inventories:

The amounts of inventories used in the determination of cost of products sold for the period covered by the statements of income were as follows:

December 1, 1955	$28,745,252
November 30, 1956	38,854,133
November 30, 1957	43,358,883
November 30, 1958	46,954,141
November 30, 1959	59,439,051
November 30, 1960	60,808,475
May 31, 1960	68,857,311
May 31, 1961	69,577,416

The inventories at these dates were priced on the basis of the lower of cost (principally first-in, first-out method) or market (replacement cost or estimated net realizable amount, whichever was appropriate).

At November 30, 1960, the inventories consisted of $37,338,021 finished and in-process products and $23,470,454 raw materials and supplies. It was not practicable to segregate amounts for inventories as between finished and in-process products and raw materials and supplies at May 31, 1961.

Note F—Policies Regarding Depreciation, Depletion, Amortization, Maintenance, and Repairs:

The Company and consolidated subsidiaries have provided for depreciation (generally straight-line method) on a basis calculated to amortize the cost of the various classes of depreciable assets over their estimated useful lives.

The estimated useful lives of the principal classifications of depreciable properties follow:

Buildings and improvements:	
Principally	20 to 40 years
Other	5 to 50 years
Machinery and equipment:	
Principally	7 to 20 years
Other	3 to 33⅓ years
Furniture and fixtures	5 to 20 years
Automobiles and trucks	3 to 5 years

Depletion of limestone and other deposits was computed on a unit rate of production basis applied to the cost of individual properties. Amounts so determined were less than percentage depletion allowances claimed for income tax purposes.

Maintenance and repairs, and expenditures for renewals and betterments not calculated to extend the useful lives or materially increase the productivity of the properties affected, were charged to costs and expenses as incurred. Other renewals and betterments were capitalized. Generally, at the time of sale or abandonment of equipment or building units, the applicable amounts of costs and accumulated depreciation were eliminated from the accounts and the net carrying amounts less proceeds of disposal were charged or credited to income.

Amounts of intangibles arising upon acquisition of companies, representing cost of investments in excess of amounts ascribed to net tangible assets acquired, are being amortized on a straight-line basis over forty years as to approximately 60% of the total and over twenty years as to the remainder.

Note G—Retirement Plans:

The Company and certain subsidiaries have contributory and noncontributory retirement plans, terminable at the option of the companies, for salaried employees. Other retirement plans have been established on behalf of hourly-paid employees.

The estimated annual cost of the plans, based upon present participation, is approximately $2,500,000. Unfunded past service costs were estimated to be approximately $8,000,000 at May 31, 1961.

Note H—Federal Trade Commission Proceedings:

Reference should be made to the paragraph captioned "Federal Trade Commission Proceedings," included in the section "Business and Properties of American-Marietta" elsewhere in this Proxy Statement, for information concerning a Federal Trade Commission complaint pending against the Company.

Note J—Retirement of 5% Cumulative Preferred Shares:

On August 3, 1961, the Board of Directors authorized the officers and the Executive Committee to take such action as may be necessary or desirable in order to redeem the outstanding 5% Cumulative Preferred Shares of the Company prior to October 9, 1961. The redemption price of the Preferred Shares is $105 per share. The long-term debt restrictions referred to in Note C have been waived with respect to such redemption.

AGREEMENT OF CONSOLIDATION

AGREEMENT dated as of August 1, 1961, between AMERICAN-MARIETTA COMPANY ("A-M"), an Illinois corporation, and THE MARTIN COMPANY ("Martin"), a Maryland corporation, such corporations being hereinafter called the "Constituent Companies."

1. Consolidation

Upon the terms and subject to the conditions hereinafter stated, A-M and Martin will be consolidated into a new Maryland corporation to be known as Martin-Marietta Corporation and hereinafter called the "Consolidated Company." Proposed Articles and Plan of Consolidation complying with the requirements of the Maryland Corporation Law and the Illinois Business Corporation Act are attached as Exhibit A to this Agreement and are hereinafter referred to as the "Articles."

2. Retirement and Conversion of Stock

Before the consolidation, A-M will retire its 5% Cumulative Preferred Shares. In the consolidation the then stock of the Constituent Companies will be converted into stock of the Consolidated Company provided for in the Articles as follows:

Each Share of Each Class of Stock of the Constituent Companies Shown Below	Shall be	The Number of Shares of Stock of the Consolidated Company Shown Below
A-M Stock:		
All Class B Common Shares, $2 par value, outstanding at the effective date	Converted into	380,000 shares of 4½% Cumulative Preferred Stock, $100 par value
Each Common Share, $2 par value	Converted into	1 share of Common Stock, $1 par value
Martin Stock:		
Each Share of Common Stock without par value	Converted into	1.3 shares of the aforesaid Common Stock
Each Warrant to purchase a Current Stock Unit now consisting of 2.10 shares of the aforesaid Common Stock	Shall entitle the holder to purchase	a Current Stock Unit consisting of 2.73 shares of the aforesaid Common Stock

3. Procedure:

This Agreement has been approved by the boards of directors of the Constituent Companies. The A-M Board, by vote of a majority of its members, has approved the Articles as a plan of consolidation under the Illinois Business Corporation Act and has directed that the plan be submitted to a vote at a special meeting of shareholders to be held October 9, 1961. The Martin Board has adopted a resolution declaring that the proposed consolidation is advisable upon the terms and conditions set forth in the Articles as required by the Maryland Corporation Law and has directed that the Articles be submitted for action thereon at a special meeting of the Martin stockholders also to be held October 9, 1961.

If the Articles receive the favorable vote of the holders of two-thirds of the outstanding A-M Common Shares and Class B Common Shares voting together and as separate classes at the A-M meeting and the holders of a majority of the outstanding shares of Martin stock at the Martin meeting, then, on the closing date established under paragraph 4 hereof, articles of consolidation embodying the Articles in substantially the form attached hereto will be delivered to the Secretary of State of Illinois as provided by Illinois law and the Articles in substantially the form attached hereto will be filed with the Department of Assessments and Taxation of Maryland as provided by Maryland law. The consolida-

tion will be effective upon the issuance of a certificate of consolidation by the Secretary of State of Illinois and the acceptance of the Articles for record by the Department of Assessments and Taxation of Maryland, and shall thereupon be deemed to have been in effect as of the first day of the month in which it becomes effective.

The effectuation of the consolidation will not cause any interruption of the business of either Constituent Company. Officers and employees of each Constituent Company on the day on which the consolidation becomes effective will thereupon become employees of corresponding divisions of the Consolidated Company.

4. Closing Date and Closing

The closing date has been initially established as October 10, 1961, but may be postponed up to one week by either Constituent Company if it is unable to satisfy the conditions of the other Company's obligation on that date and may also be postponed in one or more postponements to a date not later than December 31, 1961, by mutual agreements of the boards of directors of both Companies. On the closing date a closing will be held at Baltimore National Bank, Baltimore, Md., at 10:00 A. M., local time, at which the Constituent Companies will exchange opinions of counsel and other documents required to satisfy the conditions of their obligations. Arrangements will be made for the concurrent filing of the Articles in Illinois and Maryland immediately following closing.

5. Proxy Material, Representations and Warranties

Each of the Constituent Companies has supplied to the other for inclusion in the other's proxy statement the information, including financial statements, called for by the rules of the Securities and Exchange Commission applicable to Martin. Each of the Constituent Companies represents and warrants that the proxy information supplied by it is an accurate description of its business and property and does not contain any material misstatement of fact or omit to state any material fact necessary to make the statements therein not misleading; that the financial statements included therein were prepared in conformity with generally accepted accounting principles applied on a consistent basis and present fairly the results of operations and financial position of the Company in question for the periods and at the dates shown; and that the Company has no material liabilities, contingent or otherwise, not disclosed in the proxy information and financial statements supplied by it. In addition, each Constituent Company represents and warrants that

(a) the Company and (in the case of A-M) each of its active subsidiaries is a corporation validly organized and existing in good standing under the laws of the jurisdiction of its incorporation and duly qualified to do business in all states or countries where it owns or leases real property of material importance to its business, maintains a substantial inventory or conducts manufacturing operations;

(b) the Company or (in the case of A-M) one of its subsidiaries has good and marketable title to all assets reflected in the balance sheet included in the proxy information submitted by it except assets disposed of since the balance sheet date in the ordinary course of business and holds such assets free of liens, encumbrances and adverse claims other than (i) those shown on the balance sheet; (ii) such encumbrances as result from taxes not yet due; (iii) easements, rights of way and other minor encumbrances which in the aggregate do not impair the use of the assets in the business; (iv) the Company and (in the case of A-M) each of its active subsidiaries has properly prepared and filed all required tax returns and paid the amounts shown due thereon (except, in the case of Martin, certain state taxes the applicability of which has not been finally determined), the provisions for federal income taxes in the financial statements submitted in its proxy material are adequate to cover such taxes (whether or not disputed), and its federal income tax returns have been examined by the Internal Revenue Service through 1955 in the case of A-M and 1957 in the case of Martin and no deficiency resulting from such examinations has been proposed which has not been paid or settled;

(c) since the date of the balance sheet of the Company included in its proxy material there has been no material adverse change in the business, properties or financial condition of the Company (including, in the case of A-M, the Company and its subsidiaries, considered as a whole), and no material change in its assets or liabilities other than in the ordinary course of business, and

since that date the Company has not (A) issued, sold or purchased any shares of its capital stock or any options, warrants or rights to purchase any such shares (except, in the case of Martin, shares issued upon exercise of options and warrants outstanding on the balance sheet date and options granted under its restricted stock option plans subsequent to such date as shown in its proxy material) or (B) paid or declared any dividend or made any distribution to its stockholders except as set forth in the schedule of dividends in subparagraph (d) below, and neither the Company nor (in the case of A-M) any of its subsidiaries has (C) incurred or agreed to incur any long-term indebtedness for borrowed money, or (D) mortgaged or pledged any of its assets or contracted to do so, or (E) sold or disposed of any material assets or contracted to do so other than in the ordinary course of business, or (F) incurred any material liability or commitment or entered into any material transaction except in the ordinary course of business or in relation to this Agreement, or (G) made any substantial change in the manner of conducting its business; and

(d) between the date hereof and the date when the consolidation actually becomes effective, neither of the Constituent Companies will take any action of the kinds specified in clauses (A) through (G) of subparagraph (c) above without the concurrence of the other, except that (i) A-M may retire its 5% Cumulative Preferred Shares and issue additional Common Shares upon conversion of Class B Common Shares provided that an equal number of Common Shares are surrendered as a capital contribution so that there is no net increase in the number of A-M Common Shares outstanding, (ii) Martin may issue options for a number not to exceed 5,000 shares of its Common Stock under its 1958 Stock Option Plan, and (iii) the dividends listed below may be paid:

A-M dividends:

(a) Regular $1.25 per Preferred Share on or about August 1, 1961

(b) Regular $.25 per Common Share on or about August 1, 1961

(c) Special $.17 per Common Share on or about October 1, 1961 to cover extra two months between A-M's regular dividend date of August 1 and the Consolidated Company's proposed first dividend date of approximately December 31, 1961

Martin dividends:

(a) Regular $.25 per share at end of September 1961.

6. Examinations by Constituent Companies

Before the closing date each Constituent Company may examine the properties and records of the other Constituent Company and (in case of A-M) its subsidiaries (except as such examination may be restricted for security reasons) to determine the accuracy of the other Company's representations and warranties, and each Constituent Company will cause its officers and employees to cooperate in such examination and disclose pertinent and unrestricted information. If for any reason the consolidation does not become effective, information obtained through such examination shall be retained in confidence.

7. Conditions of Constituent Companies' Obligations

The obligation of each Constituent Company to execute and deliver the Articles and make the consolidation effective is subject to the approval of stockholders of both Constituent Companies specified in paragraph 3 and to the satisfaction in all material respects of the following conditions at or before closing; provided, however, that the board of directors of either Company, in its discretion, may waive the failure of the other Company to fulfill any of the conditions set forth below:

(a) The Company's examination shall not have disclosed any inaccuracy in the other Company's representations and warranties set forth in paragraph 5, such representations and warranties shall be correct on and as of the closing date, and the Company shall have received a certificate of the President or a Vice President of the other Company to that effect;

(b) The other Company shall not have defaulted in any obligation hereunder required to be performed by it before closing;

(c) The Company shall have received an opinion of counsel for the other Company (Ballard, Spahr, Andrews & Ingersoll, Philadelphia, Pa. being counsel for A-M, and Miles & Stockbridge, Baltimore, Md. being counsel for Martin) to the effect that:

(i) the Company represented by such counsel and (in the case of A-M) each of its domestic and Canadian subsidiaries holding material property or contributing materially to income (if any) is a duly organized corporation existing in good standing under the laws of its jurisdiction of incorporation with corporate power to own its properties and conduct its business as now conducted and is qualified to transact business and in good standing in jurisdictions where it owns or leases real property of material importance to its business, maintains a substantial inventory or conducts manufacturing operations, and the stock of each such subsidiary owned by its parent is validly issued, fully paid and non-assessable. [In giving such opinion with respect to A-M subsidiaries, Ballard, Spahr, Andrews & Ingersoll may rely on opinions of counsel for such subsidiaries.]

(ii) such counsel does not know or have reason to believe that there is any pending or threatened litigation, proceeding or investigation not disclosed in the proxy information supplied by the Company represented by such counsel which might result in a material adverse change in the business, properties or financial condition of such Company (including, in the case of A-M, the Company and its subsidiaries, considered as a whole), or which questions the validity of this Agreement or the consolidation to be effected hereunder.

(iii) the Company represented by such counsel has full power and authority to become party to the consolidation to be effected hereunder; such consolidation will not be a breach of, or result in a default or any accelerated liability under, such Company's charter or any indenture, loan agreement, pension trust, government contract, or other instrument by which such Company is bound on the closing date; all corporate and other proceedings required to be taken by such Company to authorize this Agreement and the consolidation have been validly taken; and no filing with or consent of any governmental or other authority is required in connection with the consolidation other than the listing of the Consolidated Company's stock and warrants on the appropriate stock exchanges and registration thereof under the Securities Exchange Act of 1934, and such listing and registration will become effective on notice of the effectiveness of the consolidation; and

(iv) the vote of stockholders of the Company represented by such counsel provided for in paragraph 3 operates to authorize the consolidation as far as such Company is concerned and binds all such Company's stockholders except for the statutory right of dissenters to receive the appraised value of their shares.

In giving the foregoing opinion Ballard, Spahr, Andrews & Ingersoll may rely as to Illinois law on the opinion of Illinois counsel satisfactory to them and to Miles & Stockbridge;

(d) At the closing date there shall be no litigation pending or threatened in which an injunction is or may be sought against the consolidation;

(e) The Company shall have received satisfactory assurances that no person deemed to be in control of either of the Constituent Companies within the meaning of the Securities Act of 1933, as amended and the Rules thereunder will make distribution to the public of securities of the Consolidated Company received by him in the consolidation without registration thereof under said Act, except as permitted by paragraph (d) of Rule 133 under said Act.

(f) All proceedings and documents in connection with this Agreement and the consolidation shall have been approved by counsel for the Company in question.

8. Management of Consolidated Company

The directors of the Consolidated Company shall be as set forth in the Articles hereto attached. It is the present intention of the parties that George M. Bunker will be elected President and chief executive officer of the Consolidated Company and that Grover M. Hermann will be elected Chairman of the Board.

9. Termination

This Agreement shall terminate automatically if closing is not held on or before December 31, 1961. Either of the Constituent Companies, by resolution of its board of directors, may terminate this Agree-

ment if the conditions required to be fulfilled by the other Company as specified in paragraph 7 are not satisfied on the closing day. The two Constituent Companies, each acting by its board of directors, may also terminate this Agreement and abandon the consolidation by mutual consent at any time before the consolidation becomes effective. In the event of any termination under this paragraph, neither of the Constituent Companies will have any liability to the other in connection with this Agreement for costs expenses, loss of anticipated profits or otherwise.

10. Issuance of Stock Certificates of the Consolidated Company

After the consolidation becomes effective, holders of certificates for shares of stock of the Constituent Companies will be entitled to receive in exchange therefor certificates for the shares of stock of the Consolidated Company into which their shares of the Constituent Companies have been converted, except that holders of certificates for shares of Martin Common Stock will not be entitled to receive certificates for fractional shares of the Consolidated Company's Common Stock. Arrangements will be made for the matching and combination or the purchase and sale of fractional interests in respect of Martin certificates surrendered for exchange within 60 days after the consolidation becomes effective.

11. Miscellaneous

(a) Each Constituent Company represents that it has not dealt with any broker in connection with this Agreement or the consolidation contemplated hereunder and that, insofar as is known to its management, no broker or other person is entitled to or claiming any commission or finder's fee in connection therewith.

(b) Neither Constituent Company may assign its rights hereunder and nothing herein contained shall confer any rights on any person not a party hereto.

(c) Notices in connection with this Agreement will be sufficiently delivered if delivered or mailed to A-M at 101 East Ontario Street, Chicago 11, Illinois, with a copy to John F. Donoho, Vice President, at 80 Pine Street, New York 5, New York; and to Martin at Friendship International Airport, Maryland, Attention: W. L. Lucas, Secretary, with a copy to Clarence Miles, Esq., Miles & Stockbridge, 10 Light Street, Baltimore 2, Maryland.

(d) This Agreement supersedes all previous negotiations and contains the entire understanding between the parties. It may be modified only in writing signed by the party against which the modification is asserted.

IN WITNESS WHEREOF the Constituent Companies have caused this Agreement to be signed in their names by the Chairmen of their respective Boards of Directors, each thereunto duly authorized, and their corporate seals to be affixed hereto and duly attested.

ARTICLES AND PLAN OF CONSOLIDATION
CONSOLIDATING
THE MARTIN COMPANY AND AMERICAN-MARIETTA COMPANY
TO FORM
MARTIN-MARIETTA CORPORATION

Articles and Plan of Consolidation, entered into this .....day of ....., 19...., between The Martin Company, a Maryland corporation, and American-Marietta Company, an Illinois corporation.

ARTICLE I

The corporations which are parties to these Articles and Plan of Consolidation are The Martin Company (hereinafter called "Martin"), a corporation, having capital stock, organized and existing under the laws of the State of Maryland, and American-Marietta Company (hereinafter called "A-M"), a corporation, having capital stock, organized and existing under the laws of the State of Illinois. Martin and A-M have agreed, pursuant to requisite authority, to consolidate and thereby form a new corporation. The terms and conditions of the consolidation and the mode of carrying the same into effect shall be as herein set forth.

ARTICLE II

The name of the new corporation, resulting from the said consolidation, shall be "Martin-Marietta Corporation" (hereinafter called "Corporation"), and shall be formed under the laws of the State of Maryland.

ARTICLE III

Martin was incorporated on December 5, 1928, under the general statutes of the State of Maryland authorizing the formation of corporations. A-M was incorporated on September 12, 1930, under the general statutes of the State of Illinois, authorizing the formation of business corporations. A-M is qualified to do business in the State of Maryland, having so qualified on November 28, 1955.

ARTICLE IV

The charter of the Corporation shall be as stated in this ARTICLE IV:

FIRST: **Name.** The name of the corporation (which is hereinafter called "Corporation") is Martin-Marietta Corporation.

SECOND: **Period of Duration.** The period of duration of the Corporation is perpetual.

THIRD: **Purposes, Objects and Powers.** The purposes for which the Corporation is formed and the business or objects to be carried on and promoted by it are as follows:

Clause (1). To engage in and carry on the business of creating, developing, manufacturing, testing, transporting and making ready for use all kinds of missiles, electronics, electronic devices and substances, spacecraft, defense equipment and systems, and nuclear reactors and devices, and modifying, repairing, altering, licensing, buying, selling and dealing in all such articles and other property of every kind and character used in connection therewith.

Clause (2). To engage in and carry on the business of manufacturing, repairing altering, using, licensing, buying, selling and dealing in and with vehicles of all kinds, engines, motors, machinery, in-

struments, parts, equipment, appliances, devices, articles and materials of all kinds for use on or in connection therewith and the manufacture thereof.

Clause (3). To manufacture, buy, sell and deal in and with limestone, lime, concrete, concrete admixtures, cement, magnesite, brick, tile, refractories, asphalt, mortar, and products thereof; pipes, tubes, conduits and fittings, building materials and products thereof; chemicals; paints, pigments, coatings, finishes, resins and adhesives; shot, grit and metal powders; agricultural, road building, pipe laying, pulverizing, dust collecting and other machinery and equipment; mops, polishes, cleaners and waxes; and any and all other similar or related products.

Clause (4). To engage in and carry on the business of importing, exporting, manufacturing, producing, buying, selling and otherwise dealing in and with, goods, wares, and merchandise of every class and description.

Clause (5). To engage in and carry on any other business which may conveniently be conducted in conjunction with any of the business of the Corporation.

Clause (6). To buy, quarry, mine, grow, manufacture, process, own, invest in, sell, mortgage, pledge, lease, assign, transfer or otherwise deal in or with goods, wares, merchandise, supplies, materials, trees, crops, minerals, parts, machinery, equipment, products and other personal property of every kind, class and description.

Clause (7). To purchase, lease, hire or otherwise acquire, hold, own, develop, improve and dispose of, and to aid and subscribe toward the acquisition, development or improvement of real and personal property and rights and privileges therein, suitable or convenient for any of the business of the Corporation.

Clause (8). To purchase, lease, hire or otherwise acquire, hold, own, construct, erect, improve, manage and operate, and to aid and subscribe toward the acquisition, construction or improvement of, plants, mills, factories, works, buildings, machinery, equipment and facilities and any other property or appliances which may appertain to or be useful in the conduct of any of the business of the Corporation.

Clause (9). To acquire all or any part of the good will, rights, property and business of any person, firm, association or corporation heretofore or hereafter engaged in any business similar to any business which the Corporation has the power to conduct, and to hold, utilize, enjoy and in any manner dispose of, the whole or any part of the rights, property and business so acquired, and to assume in connection therewith any liabilities of any such person, firm, association or corporation.

Clause (10). To apply for, obtain, purchase, or otherwise acquire, any patents, copyrights, licenses, trade marks, trade names, rights, processes, formulas, and the like, which may seem capable of being used for any of the purposes of the Corporation; and to use, exercise, develop, grant licenses in respect of, sell and otherwise turn to account, the same.

Clause (11). To acquire by purchase, subscription or otherwise, and to hold, sell, assign, transfer, exchange, lease, mortgage, pledge, or otherwise dispose of, any shares of stock of, or voting trust certificates for any shares of stock of, or any bonds or other securities or evidences of indebtedness issued or created by, any other corporation or association, organized under the laws of the State of Maryland or of any other state, territory, district, colony or dependency of the United States of America, or of any foreign country; and while the owner or holder of any such shares of stock, voting trust certificates, bonds, or other obligations, to possess and exercise in respect thereof any and all the rights, powers, and privileges of individual holders, including the right to vote on any shares of stock so held or owned; and upon a distribution of the assets or a division of the profits of the Corporation, to distribute any such shares of stock, voting trust certificates, bonds or other obligations, or the proceeds thereof, among the stockholders of the Corporation.

Clause (12). To issue shares of its stock of any class, in the manner permitted by law, to raise money for any of the purposes of the Corporation, or in payment for property purchased, or for any other lawful consideration.

Clause (13). To borrow or raise money for any of the purposes of the Corporation and to issue bonds, debentures, notes or other obligations of any nature, and in any manner permitted by law, for money so borrowed or in payment for property purchased, or for any other lawful consideration, and to secure the payment thereof and of the interest thereon, by mortgage upon, or pledge or conveyance or assignment in trust of, the whole or any part of the property of the Corporation, real or personal,

including contract rights, whether at the time owned or thereafter acquired, and to sell, pledge, discount or otherwise dispose of such bonds, notes or other obligations of the Corporation for its corporate purposes.

Clause (14). To aid in any manner any corporation or association, any bonds, or other securities or evidences of indebtedness of which, or shares of stock in which, are held by or for the Corporation, or in which, or in the welfare of which, the Corporation shall have any interest, and to do any acts or things designed to protect, preserve, improve, or enhance the value of, any such bonds or other securities or evidences of indebtedness, or such shares of stock, or any property of the Corporation.

Clause (15). To guarantee the payment of dividends upon any shares of stock of, or the performance of any contract by, any other corporation or association and to endorse or otherwise guarantee the payment of the principal and interest, or either, of any bonds, debentures, notes, securities, or other evidences of indebtedness created or issued by any other corporation or association.

Clause (16). To carry out all or any part of the foregoing objects as principal, factor, agent, contractor, or otherwise, either alone or through or in conjunction with any person, firm, association or corporation, and in any part of the world, and, in carrying on its business and for the purpose of attaining or furthering any of its objects and purposes, to make and perform any contracts and to do any acts and things, and to exercise any powers suitable, convenient or proper for the accomplishment of any of the purposes herein enumerated or incidental to the powers herein specified, or which at any time may appear conducive to or expedient for the accomplishment of any of such purposes.

Clause (17). To carry out all or any part of the aforesaid purposes, and to conduct its business in all or any of its branches in any or all states, territories, districts, colonies and dependencies of the United States of America and in foreign countries; and to maintain offices and agencies in any or all states, territories, districts, colonies and dependencies of the United States of America and in foreign countries.

It is the intention that the objects and purposes specified in the foregoing clauses of this subdivision THIRD shall not, unless otherwise specified herein, be in any wise limited or restricted by reference to, or inference from, the terms of any other clause of this or any other article in this charter, but that the objects and purposes specified in each of the clauses of this subdivision THIRD shall be regarded as independent objects and purposes. It is also the intention that said clauses be construed both as purposes and powers; and generally, that the Corporation shall be authorized to exercise and enjoy all other powers, rights, privileges granted to, or conferred upon, corporations of this character, by the laws of the State of Maryland, and the enumeration of certain powers as herein specified is not intended as exclusive of, or as a waiver of, any of the powers, rights or privileges granted or conferred by the laws of said state now or hereinafter in force.

FOURTH: **Principal Office and Resident Agent.** The post office address of the place in which the principal office of the Corporation in the State of Maryland is located is 10 Light Street, Baltimore, Maryland. The Resident Agent of the Corporation is Clarence W. Miles, whose post office address is 10 Light Street, Baltimore, Maryland; said Resident Agent is a citizen of the State of Maryland and actually resides therein.*

FIFTH: **Directors.** The number of Directors of the Corporation shall be eighteen (18), which number may be increased or decreased pursuant to the By-Laws of the Corporation but which never shall be less than five (5); and the names of the directors who shall act until their successors are duly chosen and qualified are: **

William B. Bergen	Leigh R. Gignilliat, Jr.	Clarence W. Miles	Alexander B. Royce
George M. Bunker	Grover M. Hermann	John E. Parker	Duncan M. Spencer
William A. Burns	H. N. Huntzicker	Robert E. Pflaumer	John L. Sullivan
William J. Cabaniss	J. Clifford Knochel	Everett H. Pixley	
John F. Donoho	Ray L. Oughton	W. Trent Ragland, Jr.	

* Differs from form of Articles and Plan of Consolidation attached to executed Agreement of Consolidation in that addresses in FOURTH have been changed.

** Differs from form of Articles and Plan of Consolidation attached to executed Agreement of Consolidation, in that one substitution has been made in the persons listed in FIFTH.

SIXTH: **Authorized Shares of Stock.** The total number of shares of stock of all classes which the Corporation has authority to issue is 40,380,000 shares, divided into 380,000 shares of 4½% Cumulative Preferred Stock of the par value of $100 per share and 40,000,000 shares of Common Stock of the par value of $1 per share. The aggregate par value of all shares having par value of all classes is $78,000,000.

A description of each class with the preferences, conversion and other rights, voting powers, restrictions, limitations as to dividends and qualifications of each class is as follows:

4½% Cumulative Preferred Stock

1. *Dividends.*

The holders of 4½% Cumulative Preferred Stock (hereinafter called "Preferred Stock") shall be entitled to receive, when and as declared by the Board of Directors, dividends at the rate of 4½% of the par value thereof per year, and no more. Such dividends shall be cumulative from the first day of the month in which the Corporation comes into existence and shall be payable quarterly on the first days of January, April, July and October in each year. The Corporation shall not declare or pay any dividend or make any distribution on the Common Stock or on any other class of stock, ranking as to dividends or assets subordinate to the Preferred Stock, other than dividends and distributions (herein called "unrestricted stock dividends and distributions") paid or made solely in Common Stock or another class of stock of the Corporation ranking as to dividends and assets subordinate to the Preferred Stock, and neither the Corporation nor any subsidiary of the Corporation shall make any payment or apply any of its assets to purchase or redeem any Common Stock or any other class of stock of the Corporation ranking as to dividends or assets on a parity with or subordinate to the Preferred Stock, unless at the time dividends for all past quarterly dividend periods and the then current quarterly dividend period on all outstanding shares of Preferred Stock have been paid, or declared and set aside for payment, in full and unless, after giving effect to such action, the sum of

(a) the aggregate amounts declared and paid or payable as dividends or distribution (other than unrestricted stock dividends and distributions) on all shares of stock of all classes of the Corporation subsequent to the date on which it came into existence; plus

(b) the excess of the aggregate amounts applied to ,or set apart for, the purchase or redemption of shares of Common Stock or any other class of stock of the Corporation ranking as to dividends or assets subordinate to the Preferred Stock subsequent to the date on which the Corporation came into existence over the net cash proceeds or fair value (as determined by the Corporation's board of directors) of property received by the Corporation subsequent to that date as consideration for the issuance or delivery of Common Stock or any other class of stock of the Corporation ranking as to dividends and assets subordinate to the Preferred Stock

will not exceed the consolidated net income (determined in accordance with generally accepted accounting principles) of the Corporation and its subsidiaries (if any) subsequent to November 30, 1961 plus $45,000,000.

2. *Liquidation.*

In the event of voluntary or involuntary liquidation, dissolution or winding up of the Corporation, the holders of Preferred Stock shall be entitled to receive in cash from the assets of the Corporation (whether capital or surplus), prior to any payment to the holders of Common Stock or of any other class of stock of the Corporation ranking as to assets subordinate to the Preferred Stock, the sum of $100 for each share thereof, plus an amount equal to accrued and unpaid dividends thereon computed to the date at which payment thereof is made available (whether or not earned or declared), plus, if the liquidation, dissolution or winding up is voluntary, a premium of $5 per share. A consolidation or merger to which the Corporation shall be a party shall not be deemed a liquidation of the Corporation within the meaning of this paragraph.

3. *Redemption and Purchase.*

The Corporation may, at its option, redeem all, but not less than all, the shares of Preferred Stock outstanding at any time after October 1, 1964, at a price equal to $105 per share plus an amount equal to accrued and unpaid dividends thereon computed to the date fixed for redemption (whether or not earned or declared). Notice of such redemption shall be given to the holders of record of the Preferred Stock by mailing such notice at least 30 and not more than 60 days before the redemption date to such holders at their addresses appearing on the books of the Corporation. The Corporation, upon mailing such notice or irrevocably authorizing the bank or trust company hereinafter mentioned to mail the same, may deposit an amount equal to the redemption price with a bank or trust company in Chicago, Illinois having a combined capital and surplus reported in its last published report in excess of $5,000,000 to be held in trust for payment to the holders of Preferred Stock at any time after such deposit. Upon such deposit, or if no deposit is made, then from and after the date fixed for redemption (unless the Corporation shall default in paying the redemption price), the Preferred Stock shall cease to be outstanding and the holders thereof shall cease to be stockholders with respect thereto. All shares of Preferred Stock redeemed or purchased by the Corporation, whether through the sinking fund hereinafter provided for or otherwise, shall be cancelled and shall not be reissued.

4. *Voting Rights.*

The holders of shares of the Preferred Stock shall have no right to vote and shall not be entitled to notice of any meeting of stockholders of the Corporation or to participate in such meeting, except as required by law or as herein otherwise expressly provided. If at any time the Corporation shall have failed (a) to pay, or declare and set apart for payment, dividends on the Preferred Stock and such default (whether or not in respect of consecutive dividends) shall be in an aggregate amount equal to four quarterly dividends on all outstanding shares of Preferred Stock, or (b) to set aside or apply, when required, the sinking fund hereinafter provided for, then in any such event, the number of directors of the Corporation shall forthwith be automatically increased by the smallest number that will be not less than one-third of the total number of directors after giving effect to such increase. The holders of Preferred Stock shall have the right, voting as a class, to elect such additional directors at a special meeting of the holders of Preferred Stock, which shall be called by the Secretary of the Corporation upon demand of the holders of 10% or more of the outstanding shares thereof, and at each subsequent annual meeting of stockholders of the Corporation until such time as dividends payable for all past quarterly dividend periods and the then current quarterly dividend period on all outstanding shares of Preferred Stock shall have been paid, or declared and set apart for payment, in full, and the Corporation shall have set aside an amount equal to all arrearages in the sinking fund and applied the same to the redemption of Preferred Stock as provided in paragraph 7, at which time the terms of the additional directors elected by the holders of Preferred Stock shall terminate, the number of directors shall be correspondingly reduced, and the voting rights of the holders of Preferred Stock shall cease, subject to revesting in the event of each additional default in payment of dividends in an amount equal to four quarterly dividends or in setting aside or applying the sinking fund as aforesaid.

5. *Action by the Corporation Requiring Approval of Preferred Stock.*

The Corporation shall not, without the affirmative vote or written consent of the holders of at least two-thirds of the then outstanding shares of Preferred Stock:

(1) By charter amendment or in a merger or consolidation or in any other manner: (a) increase the number of authorized or outstanding shares of Preferred Stock, or (b) decrease the par value of shares of Preferred Stock, or (c) effect an exchange or reclassification of any outstanding shares of Preferred Stock, or a cancellation of any of such shares except upon purchase or redemption thereof, or (d) change the designations, preferences, qualifications, limitations, restrictions or special or relative rights of the Preferred Stock, or (e) change the outstanding shares of Preferred Stock into the same or a different number of shares of any other class of stock, or (f) create any shares of stock of any other class, or any obligations, exchangeable for or convertible into shares of Preferred Stock, or (g) create or authorize or permit to

be outstanding any kind of stock, or any obligations or other securities exchangeable for or convertible into any kind of stock, having rights or preferences prior or superior to, or on a parity with, the Preferred Stock, or increase the rights or preferences of any class of stock having rights or preferences prior or superior to, or on a parity with, the Preferred Stock, or (h) cancel or otherwise affect dividends on the Preferred Stock which have accrued but have not been paid, or

(2) Issue or sell any shares of Preferred Stock (including shares acquired through the sinking fund) or of any class of stock ranking as to dividends or assets prior to or on a parity with the Preferred Stock or in any other manner increase the number of outstanding shares of Preferred Stock or of any class of stock ranking as to dividends or assets prior thereto or on a parity therewith.

6. *Merger or Consolidation.*

In the event of any merger or consolidation of the Corporation any holder of Preferred Stock shall be entitled to receive payment in cash of the amount to which he would then be entitled upon a voluntary liquidation of the Corporation unless by the terms of the merger or consolidation he is entitled to shares or securities (which may be his shares of Preferred Stock) of the corporation resulting from the merger or consolidation which have a relative position and priority and rights and preferences as to other classes of capital stock of such corporation at least equal to those of the Preferred Stock immediately before the merger or consolidation.

7. *Sinking Fund.*

So long as any shares of Preferred Stock are outstanding, the Corporation shall, not later than October 1 in 1962 and in each year thereafter, set aside as a sinking fund for retirement of the Preferred Stock the amount of $1,150,000; provided, however, that the Corporation may credit against such amount the par value of any shares of Preferred Stock theretofore acquired by it otherwise than through the sinking fund and not previously used as the basis for such a credit, and provided further that the Corporation may omit provision for the sinking fund in any year with written consent of the holders of all shares of Preferred Stock then outstanding. The Corporation shall not declare or pay any dividend or make any distributions on the Common Stock or any other class of stock ranking as to dividends or assets subordinate to the Preferred Stock other than unrestricted stock dividends and distributions, and neither the Corporation nor any subsidiary of the Corporation shall make any payment or apply any of its assets to purchase or redeem any Preferred Stock (other than through the sinking fund) or any Common Stock or any other class of stock of the Corporation ranking as to dividends or assets on parity with or subordinate to the Preferred Stock, at a time when the Corporation is in default in respect of the sinking fund herein provided for.

The Corporation shall apply the sinking fund within 45 days after the setting aside thereof to the redemption of Preferred Stock at a sinking fund redemption price equal to the par value thereof plus an amount equal to accrued and unpaid dividends computed to the date fixed for redemption (whether or not earned or declared). The shares of Preferred Stock to be redeemed through the sinking fund shall be selected by lot or other equitable method; provided, however, that the holder of any share so selected shall have the right, by written notice given to the Corporation prior to the redemption date, to substitute for redemption any other share of Preferred Stock held of record by him on the redemption date; and further provided that the Corporation may, with the written consent of the holders of all shares of Preferred Stock then outstanding, redeem through the sinking fund shares of Preferred Stock which prior to the redemption date are surrendered to it for such redemption without regard to the method or equity of the selection thereof. The procedure for giving notice of redemption and the effect of depositing the redemption price shall be the same in the case of sinking fund redemptions under this paragraph as in the case of an optional redemption under paragraph 3.

Common Stock

Each outstanding share of Common Stock shall be entitled to one vote on each matter submitted to a vote at a meeting of stockholders. In all elections for directors every holder of Common Stock

shall have the right to vote, in person or by proxy, the shares owned of record by him, for as many persons as there are directors to be elected and for whose election he has a right to vote, but he shall have no right to cumulative voting.

SEVENTH: **Provisions Defining, Limiting and Regulating Powers.** The following provisions are hereby adopted for the purpose of defining, limiting and regulating the powers of the Corporation and the Directors and Stockholders, subject, however, to the provisions, conditions and restrictions set forth in subdivision SIXTH hereof:

Clause (1). The Board of Directors of the Corporation is hereby empowered to authorize the issuance from time to time of shares of its stock of any class, whether now or hereafter authorized, and securities convertible into shares of its stock of any class, whether now or hereafter authorized, for such considerations as said Board of Directors may deem advisable, subject to such limitations and restrictions, if any, as may be set forth in the by-laws of the Corporation.

Clause (2). No holders of shares of stock of the Corporation of any class shall have any preemptive or other right to subscribe for or purchase any part of any new or additional issue of stock of any class or of securities convertible into stock of any class, whether now or hereafter authorized or whether issued for money, for a consideration other than money or by way of dividend.

Clause (3). The Board of Directors shall have the power, from time to time, to determine whether any, and if any, what part, of the surplus of the Corporation shall be declared in dividends and paid to the stockholders; and to direct and determine the use and disposition of any of such surplus. The Board of Directors may in its discretion use and apply any of such surplus in purchasing or acquiring any of the shares of the stock of the Corporation, or any of its bonds or other evidences of indebtedness, to such extent and in such manner and upon such lawful terms as the Board of Directors shall deem expedient.

Clause (4). The Corporation reserves the right to make from time to time any amendments of its charter which may now or hereafter be authorized by law, including but not restricted to, any amendments changing the terms of any class of its stock by classification, reclassification or otherwise.

Clause (5). Notwithstanding any provision of law requiring any action to be taken or authorized by the affirmative vote of the holders of a designated proportion of the shares of stock of the Corporation, or to be otherwise taken or authorized by vote of the stockholders, such action shall be effective and valid, except as otherwise required by provisions of this charter relating to the Preferred Stock, if taken or authorized by the affirmative vote, at a meeting, of the holders of a majority of the total number of shares outstanding and entitled to vote thereon.

EIGHTH: **By-Laws.** The Board of Directors shall have the power, at any regular or special meeting thereof, to make and adopt by-laws, or to amend, alter or repeal any by-laws of the Corporation. The by-laws may contain any provision for the regulation and management of the affairs of the Corporation not inconsistent with law or the provisions of this charter.

NINTH: **Inspection of Records by Stockholders.** The Board of Directors shall have power to determine from time to time whether and to what extent and at what times and places and under what conditions and regulations the books, records, accounts, and documents of the Corporation, or any of them, shall be open to the inspection of stockholders, except as otherwise provided by law or by the by-laws; and, except as so provided no stockholders shall have any right to inspect any book, record, account or document of the Corporation unless authorized so to do by resolution of the Board of Directors.

TENTH: **Compensation of Members of Board of Directors and Committees thereof.** The Board of Directors in its discretion may allow, in and by the by-laws of the Corporation or by resolution, the payment of expenses, if any, to members for attendance at each regular or special meeting of the Board of Directors or of any committee thereof, and the payment of reasonable compensation to such members for their services as members of the Board of Directors, or any committee thereof, and shall fix the basis and conditions upon which such expenses and compensation shall be paid. Any member of the Board of Directors or of a committee thereof, also may serve the Corporation in any other capacity and receive compensation therefor in any form.

ELEVENTH: **Indemnification of Officers and Directors.** Each director and each officer of the Corporation, and his heirs, executors and administrators shall be indemnified by the Corporation against all costs and expenses reasonably incurred by him for advice or assistance concerning, or in connection with the defense of, any civil, criminal, administrative, or other claim, action, suit or proceeding in which he may become involved, or with which he may be threatened, by reason of his being, or having been, a director or officer of the Corporation or by reason of his serving or having served any corporation, trust, committee, firm or other organization as director, officer, employee, trustee, member or otherwise at the request of the Corporation, whether or not he continues to be a director or officer at the time of incurring such costs or expenses, except costs and expenses incurred in relation to matters as to which such director or officer shall have been derelict in the performance of his duty as such director or officer.

For the purposes of this subdivision ELEVENTH, a director or officer shall conclusively be deemed not to have been derelict in the performance of his duty as such director or officer

(a) in a matter which shall have been the subject of a claim, suit, action or proceeding to which he was a party disposed of by adjudication on the merits, unless he shall have been finally adjudged in such claim, action, suit or proceeding to have been derelict in the performance of his duty as such director or officer, or

(b) in a matter not falling within (a) next preceding if either all disinterested members of the Board of Directors or a committee of disinterested stockholders of the Corporation (excluding therefrom any director or officer) selected as hereinafter provided, shall determine that he is not derelict.

The selection of the committee of stockholders provided above may be made by unanimous action of the disinterested directors or, if there be no disinterested director or directors, by the chief executive officer of the Corporation, provided that not less than three (3) stockholders shall be selected in any case. A director or stockholder shall be deemed disinterested in a matter if he has no interest therein other than as a director or stockholder of the Corporation, as the case may be. The foregoing shall not constitute exclusive tests as to dereliction and no determination as to dereliction shall be questioned on the ground that it is made otherwise than as provided above. The Corporation may pay the fees and expenses of the stockholders or directors, as the case may be, incurred in connection with making a determination as above provided.

The foregoing indemnification shall include reimbursement of all costs and expenses reasonably incurred in settling any such claim, action, suit or proceeding or in satisfaction of any related judgment, fine or penalty, when the so doing appears to be for the best interests of the Corporation, and shall be in addition to any rights to which any director or officer may otherwise be entitled as a matter of law or otherwise.

TWELFTH: **Informal Action by Board of Directors or Committees thereof.** Any action required or permitted to be taken at any meeting of the Board of Directors, or of any committee thereof, may be taken without a meeting, if a written consent to such action is signed by all members of the Board or of such committee, as the case may be, and such written consent is filed with the minutes of proceedings of the Board or committee.

ARTICLE V

A. The total number of shares of all classes which Martin has authority to issue is 12,000,000 shares of Common Stock without par value.

B. The total number of shares of all classes which A-M has authority to issue is 29,200,000 divided into two classes as follows:

25,000,000 Common Shares of the par value of $2 per share; and

4,200,000 Class B Common Shares of the par value of $2 per share.

The aggregate par value of all such shares is $58,400,000.

ARTICLE VI

Upon the effective date of the consolidation, the authorized Capital Stock of the Corporation shall be 40,380,000 shares divided into 380,000 shares of 4½% Cumulative Preferred Stock of the par value of $100 per share and 40,000,000 shares of Common Stock of the par value of $1 per share. As a result of the consolidation, the Common Stock of Martin and the Common Shares of A-M issued and outstanding on the effective date of the consolidation will be converted into like stock of the Corporation; the Class B Common Shares of A-M issued and outstanding on the effective date of the consolidation will be converted into 380,000 shares of 4½% Cumulative Preferred Stock of the par value of $100 per share; and the holders of the warrants of Martin issued and outstanding on the effective date of the consolidation will be entitled to purchase shares of Common Stock of the Corporation of the par value of $1 per share for each warrant so held, all as hereinafter more specifically set forth:

A. As to the stock and warrants of Martin:

1. Each share of Common Stock, without par value, shall be converted into 1.3 shares of Common Stock of the Corporation, of the par value of $1 per share; provided, however, that holders of certificates of Martin's Common Stock will not be entitled to receive certificates for fractional shares of the Common Stock of the Corporation.

2. Each warrant to purchase a Current Stock Unit, now consisting of 2.10 shares of the said Common Stock of Martin, without par value, shall entitle the holder thereof to purchase a Current Stock Unit consisting of 2.73 shares of Common Stock of the Corporation, of the par value of $1 per share.

B. As to the stock of A-M:

1. The Class B Common Shares outstanding on the effective date of the consolidation shall be converted into 380,000 shares of 4½% Cumulative Preferred Stock of the Corporation of the par value of $100 per share.

2. Each Common Share shall be converted into one share of Common Stock of the Corporation, of the par value of $1 per share.

Except as hereinabove set forth no other consideration shall be paid, transferred or issued by the Corporation for shares of Common Stock and warrants of Martin or for shares of A-M.

ARTICLE VII

The principal office of Martin in the State of Maryland is located in Baltimore County. The principal office of A-M in the State of Maryland is located in Baltimore City, (not located in any county). Martin owns property, the title to which could be affected by the recording of an instrument among the land records in the following counties of the State of Maryland: Baltimore County and Anne Arundel County. A-M owns property, the title to which could be affected by the recording of an instrument among the land records, in the following counties of the State of Maryland: Allegany County, Howard County and Washington County, and in Baltimore City (not located in any county).

ARTICLE VIII

The Articles and Plan of Consolidation were duly advised by the Board of Directors and approved by the stockholders of Martin in the manner and by the vote required by the laws of the State of Maryland and by the charter of Martin.

ARTICLE IX

The Articles and Plan of Consolidation were duly advised, authorized and approved in the manner

and by the vote required by the charter of A-M and by the laws of the State of Illinois, under which A-M was organized.

ARTICLE X

Upon the effective date of the consolidation:

A. The separate existences of Martin and A-M shall cease.

B. All the property, rights, privileges, powers and franchises of Martin and of A-M, of whatever nature and description, of a public as well as of a private nature, shall be transferred to, vest in and devolve upon the Corporation without further act or deed; and all property, rights, privileges, powers and franchises, and all and every other interest of Martin and of A-M shall be thereafter as effectually the property of the Corporation as they were of Martin and of A-M.

ARTICLE XI

On and after the effective date of the consolidation:

A. All debts, obligations, liabilities and duties of Martin and of A-M shall thenceforth attach to the Corporation, and may be enforced against it to the same extent as if said debts, obligations, liabilities and duties had been incurred or contracted by it; and any claim existing or action or proceeding pending by or against either Martin or A-M may be prosecuted to judgment or decree as if the consolidation had not taken place, or the Corporation, upon the motion of the Corporation or of any party, may be substituted as a party in place of Martin or A-M, as the case may be, and any such judgment or decree against Martin or A-M shall constitute a lien upon the property of the Corporation;

B. The title to any real estate shall not revert or be in any way impaired by reason of the consolidation, but all rights of creditors and all liens upon any property of Martin or A-M shall be preserved unimpaired. Nothwithstanding the provisions of Article X hereof, confirmatory deeds, assignments or other like instruments, when deemed desirable to evidence such transfer, vesting or devolution of any property, right, privilege or franchise, may at any time, or from time to time, be made and delivered in the name of Martin or A-M, as the case may be, by the last acting officers thereof, or by the corresponding officers of the Corporation.

ARTICLE XII

Anything herein contained to the contrary notwithstanding, the proposed consolidation herein set forth may be abandoned at any time prior to the effective date of consolidation, (i) by either Martin or A-M, by resolution of its Board of Directors, if the conditions of that Company's obligations, as set forth in the Agreement of Consolidation between the two companies dated as of August 1, 1961, are not satisfied, or (ii) by Martin and A-M, each acting by its Board of Directors, by mutual consent, for any reason; and the proposed consolidation shall be deemed abandoned if the closing provided for in said Agreement of Consolidation is not held on or before December 31, 1961.

ARTICLE XIII

The consolidation referred to herein shall become effective upon the issuance of a certificate of consolidation by the Secretary of State of the State of Illinois and the acceptance of the Articles and Plan of Consolidation for record by the Department of Assessments and Taxation of the State of Maryland.

The corporations party to these Articles and Plan of Consolidation have agreed that, notwithstanding the effective date as hereinabove established, the consolidation, if and when effective under the laws of the States of Maryland and Illinois, shall be effective for accounting purposes only as of the opening of business on October 1, 1961. Appropriate property, financial, accounting, statistical and other corporate records of Martin, A-M and the Corporation shall be adjusted or made, as the case may be, to reflect such effects of the consolidation as of October 1, 1961.

IN WITNESS WHEREOF, Martin and A-M, the parties to the consolidation, have caused these Articles and Plan of Consolidation to be signed in their respective corporate names and on their behalf by their respective President or Vice-President and their respective corporate seals to be hereunto affixed and attested by their respective Secretaries or Assistant-Secretaries, the day and year first above written.

ATTEST: THE MARTIN COMPANY

..... By .....
Secretary President

AMERICAN-MARIETTA COMPANY

..... By .....
Secretary President

STATE OF MARYLAND, COUNTY OF , TO WIT:

On this day of , 1961, before me, the undersigned, a Notary Public of the State and County aforesaid, personally appeared who made oath in due form of law that he is the President of The Martin Company and acknowledged that he executed the foregoing Article and Plan of Consolidation by due authority of said Corporation; at the same time also appeared who made oath in due form of law that he was the Secretary of the meeting duly held by the stockholders of The Martin Company at which the consolidation set forth in the aforegoing Articles and Plan of Consolidation was approved, and that the matters and facts set forth in said Articles and Plan of Consolidation with respect to said authorization and approval are true.

.....
Notary Public

STATE OF , COUNTY OF , TO WIT:

I HEREBY CERTIFY, that on this day of , 1961, before me the undersigned, a Notary Public of the State and County aforesaid, personally appeared who made oath in due form of law that he is the President of American-Marietta Company and acknowledged that he executed the foregoing Articles and Plan of Consolidation by due authority of said Corporation; also personally appeared who made oath in due form of law that he is the Secretary of American-Marietta Company and that the matters and facts set forth in said Articles and Plan of Consolidation with respect to authorization and approval are true.

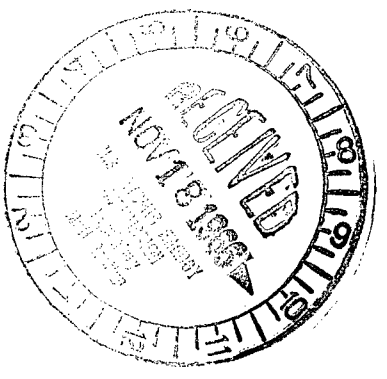
A DIVISION OF MARTIN MARIETTA

APPLICATION FOR AMENDMENT

to

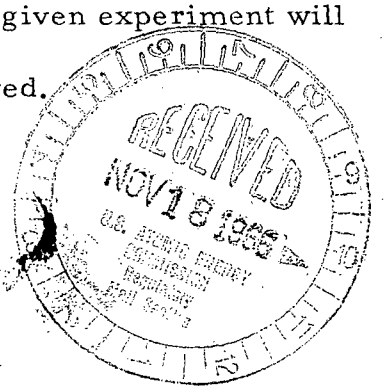
BYPRODUCT MATERIAL LICENSE NO. 19-01398-20



03416

GENERAL DISCUSSION

The Martin Marietta Corporation hereby requests that Byproduct Material License No. 19-01398-20 be amended to include the complete investigation of the physical and chemical properties of materials which has been exposed to neutron and gamma irradiation at ambient temperatures. The research and development program to be performed in the Martin radiochemistry laboratory (KJ Building) in Middle River, Maryland will be limited to 500 millicuries of any byproduct material between atomic numbers 3 and 83 inclusive. Of primary interest at this time is the investigation of the properties of Phosphorous sesquisulfide (P_4S_3), a proposed reactor coolant compound, and the compatibility between P_4S_3 and zircalloy, a proposed containment material. After irradiation at the Wright-Patterson Air Force Base - Nuclear Engineering Test Facility or other off-site location, a sufficient decay period will elapse to assure decay of short life isotopes before receipt at Martin. The radioactive material remaining from irradiation of P_4S_3 and zircalloy are Phosphorus-32, Sulfur-35 and a Zirconium-95: Niobium 95 mixture. The quantity of radioactive material handled in any given experiment will approximate one quarter of the curie amount received.

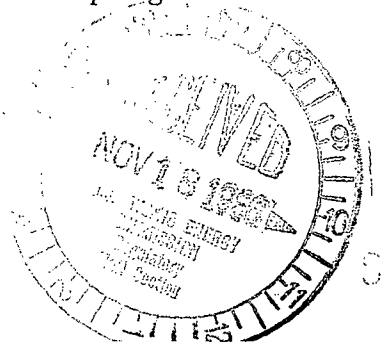


EXPERIMENTAL PROGRAM

The research and development program will include such experiments as the measurement of the inactive gas produced by radioactive decay, the definition of the gamma-beta and infra-red spectrums, and the determination of such physical properties as the melting point, the viscosity and partial dissociation of the material. Metallographic examination of coupons will be performed to define corrosion, to investigate changes in granular structures, and to determine the stress-strain curve. When deemed necessary, experimental techniques will be developed using inactive material prior to performing the experiment with radioactive material. The following discussion details the general steps and precautions to be taken during our experimental program using P_4S_3 and Zircalloy.

(1) Gamma-Beta Spectrums. Each glass vial, containing approximately 2 grams of P_4S_3 and a zircalloy-2 coupon weighing 0.08 grams, will be counted before opening with a multichannel analyzer and a methane-flow beta proportional counter. No activity will be released from the vials since they will remain sealed during these measurements.

(2) Gas Analysis. Each P_4S_3 vial will be broken behind a shielded area inside an open fan exhaust hood and a gas sample will be drawn into an evacuated sample bottle. The non-radioactive gas composition will be analyzed employing a mass-spectrograph. This sampling will be



accomplished with a valve-filter type glass transfer system so that entrainment of P_4S_3 power will be eliminated. Development of this sampling technique will be performed with inactive P_4S_3 prior to analysis of the active P_4S_3.

(3) I. R. Spectrum. Approximately one gram of P_4S_3 will be dissolved and the spectrum of the solution measured on a spectrophotometer. The dissolution will be performed behind the shielded area in an open hood and measurement of the solution will be in a controlled area in the radiochemistry laboratory. The sample of solution will be sealed in a glass vial to eliminate spillage and the transfer of the glass vial will be performed in a container to reduce possibility of breakage. Handling tools will be used to reduce personnel exposure.

(4) Melting Point. The melting point will be determined by the classical capillary tube method behind the shielded area in an open hood. The capillary tube will be sealed and the method of powder transfer to the capillary tube will be developed to reduce dispersal.

(5) Viscosity. The viscosity of the P_4S_3 will be measured in a closed glass system located in a high temperature furnace which is positioned in an exhaust controlled hood provided in case of glass breakage. A satisfactory method of sealing the active P_4S_3 powder in glass has been performed.

(6) P and S Dissociation. The presence of free sulfur and free phosphorous mixed in with the P_4S_3 will be determined by collecting elemental P in the cold end of a heated sealed glass tube and by employ-

ing the solvent extraction method. These experiments will be performed in a shielded area of the open hood.

(7) Metallographic Studies of Zircalloy-2. Determination of the compatibility of zircalloy-2 with P_4S_3 under the influence of neutron and gamma radiation will be made with standard metallographic equipment and methods in a shielded area of the open hood. The methods to be used on active zircalloy-2 coupons will be defined prior to the actual experimentation.

SAFETY CRITERIA

The likelihood of undue radiation exposure and contamination will be minimized by:

1. The radioisotope handling procedures from receipt of the P_4S_3 quartz vials to waste disposal will be under the surveillance of the Martin Company Health Physics Section.
2. The radioisotope laboratory is relatively isolated, has absolute type filtered ventilation, and continuous sampling of the stack effluent. The atmosphere in the work area is continuously sampled for airborne radioactivity by a constant air monitor.
3. All radioisotope handling will take place inside a ventilated hood and behind a shielded area within the hood to reduce personnel exposure.

4. Cold runs of the wet chemistry operations have been made using inactive P_4S_3 as simulated material in order to define the measurement procedures and to establish safe handling methods.

5. The planned radioisotope experiments will be conducted with an anticipated activity of 30 millicuries in order to further refine the handling procedures. Handling tools will be used to minimize exposure where possible.

6. Typical wet chemistry operations will involve batches of P_4S_3 containing 0.03 curie of beta emitters. Typical metallographic examination of the zircalloy-2 coupons will require handling of approximately 5×10^{-4} curies of beta and gamma emitters.

RADIOACTIVE WASTE DISPOSAL

Solid radioactive waste generated during property measurements will be removed from the hood utilizing standard packaging techniques, sealed in a plastic bag and placed in a closed I. C. C. approved waste container for ultimate disposal at an approved site. Liquid wastes shall be poured into an absorbing medium in plastic bottles and handled as solids.

HAZARD EVALUATION

Any external radiation hazard arises from the harder components of the bremsstrahlung produced by the P^{32} and S^{35} betas, and from the gammas emitted from the Zr^{95}-Nb^{95} isotopes. The exposure received by the individuals performing the experimental work will be closely monitored by the Health Physics Section. Dose rate measurement of the activated sample has been performed at the surface of a quartz vial containing two grams of P_4S_3 and a zircalloy-2 coupon. After three weeks of decay from the time of reactor shutdown, the dose rate at instrument contact at the surface of the containment vial was 400 mr/hr. It is not anticipated that any major external radiation exposure will occur during the measurement of the physical and chemical characteristics of these radioactive materials since at least an additional 9 weeks of decay time will have elapsed before receipt of the radioactive materials.

ATOMIC ENERGY COMMISSION

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved.
Budget Bureau No. 38-R027.4.

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail three copies to: U. S. Atomic Energy Commission, Washington 25, D. C. Attention: Isotopes Branch, Division of Licensing and Regulation. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30 and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital, person, etc.)*

Martin-Marietta Corporation
Martin Company
Baltimore, Maryland 21203

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1 (a).)*

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Baltimore Division

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

Byproduct License 19-1398-20 Renewal

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

James C. Neace
John H. Gray
V. Truscello

5. RADIATION PROTECTION OFFICER *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Richard J. Brisson

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*

(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*

A. Americium-241	Any form	350 curies
B. Curium-242	Any form	20 millicuries
C. Any byproduct material Atomic Nos. 3-83	Any form	80 millicuries total
D. Curium-244	Any form	D 5 millicuries
E. Polonium-210	Any form	E 60 microcuries
F. Cesium-137	Any form	F 30 microcuries
G. Promethium-147	Any form	G 20 microcuries

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

A. Preparation & examination of elements for neutron irradiation.

B. & C. Development of methods for separation of Curium-242 from Americium and fission products. Activation analysis. Spectrum decay and shielding studies.

D. - G. Preparation of plated sources for spectrum and shielding studies.

(Continued on reverse side)

Form AEC–313 (5-58) Page

TRAINING AND EXPERIENCE OF EACH INDIVIDUAL NAMED IN ITEM 4 *(Use supplemental sheets if necessary)*

8. TYPE OF TRAINING	WHERE TRAINED	DURATION OF TRAINING	ON THE JOB *(Circle answer)*	FORMAL COURS *(Circle answer)*
a. Principles and practices of radiation protection			Yes No	Yes No
b. Radioactivity measurement standardization and monitoring techniques and instruments			Yes No	Yes No
c. Mathematics and calculations basic to the use and measurement of radioactivity			Yes No	Yes No
d. Biological effects of radiation			Yes No	Yes No

9. EXPERIENCE WITH RADIATION. *(Actual use of radioisotopes or equivalent experience.)*

ISOTOPE	MAXIMUM AMOUNT	WHERE EXPERIENCE WAS GAINED	DURATION OF EXPERIENCE	TYPE OF USE

10. RADIATION DETECTION INSTRUMENTS. *(Use supplemental sheets if necessary.)*

TYPE OF INSTRUMENTS *(Include make and model number of each)*	NUMBER AVAILABLE	RADIATION DETECTED	SENSITIVITY RANGE *(mr/hr)*	WINDOW THICKNESS *(mg/cm²)*	USE *(Monitoring, surveying, measuring)*

11. METHOD, FREQUENCY, AND STANDARDS USED IN CALIBRATING INSTRUMENTS LISTED ABOVE.

12. FILM BADGES, DOSIMETERS, AND BIO-ASSAY PROCEDURES USED. *(For film badges, specify method of calibrating and processing, or name of supplier.)*

INFORMATION TO BE SUBMITTED ON ADDITIONAL SHEETS

13. FACILITIES AND EQUIPMENT. Describe laboratory facilities and remote handling equipment, storage containers, shielding, fume hoods, etc. Explanatory sketch of facility is attached. *(Circle answer)* Yes No

14. RADIATION PROTECTION PROGRAM. Describe the radiation protection program including control measures. If application covers sealed sources, submit leak testing procedures where applicable, name, training, and experience of person to perform leak tests, and arrangements for performing initial radiation survey, servicing, maintenance and repair of the source.

15. WASTE DISPOSAL. If a commercial waste disposal service is employed, specify name of company. Otherwise, submit detailed description of methods which will be used for disposing of radioactive wastes and estimates of the type and amount of activity involved.

CERTIFICATE (This item must be completed by applicant)

16. THE APPLICANT AND ANY OFFICIAL EXECUTING THIS CERTIFICATE ON BEHALF OF THE APPLICANT NAMED IN ITEM 1, CERTIFY THAT THIS APPLICATION IS PREPARED IN CONFORMITY WITH TITLE 10, CODE OF FEDERAL REGULATIONS, PART 30, AND THAT ALL INFORMATION CONTAINED HEREIN, INCLUDING ANY SUPPLEMENTS ATTACHED HERETO, IS TRUE AND CORRECT TO THE BEST OF OUR KNOWLEDGE AND BELIEF.

Attention: Dr. J. A. McBride, Director
Division of Material Licensing

Gentlemen:

Re: Request for Release for Public Use of a Facility Formerly Used for Nuclear Activities by the Martin Marietta Corporation

Isotopes' Nuclear Systems Division has recently completed decontamination of the Martin Marietta Corporation Radiochemistry Laboratory ("KJ" Building). This building was formerly used by Martin Marietta for those activities previously authorized under AEC Byproduct Material License Nos. 19-1398-32 and 19-1398-33.

The resultant radioactive wastes have been packaged preparatory to shipment to an authorized disposal site, and the results of the final radiological survey conducted by the Isotopes' health physics staff are transmitted herewith for your information.

Review of the attached survey data indicates that the proposed AEC guides governing the abandonment of nuclear facilities have been met, therefore, the Martin Marietta Corporation hereby requests release of the subject building for future public use.

We would appreciate receiving approval of this request at your earliest convenience. Please contact me directly on 301/761-5200, extension 340 if I can be of assistance in this matter.

Sincerely,

Ross G. Macaulay
Director - Contracts

"KJ" BUILDING SMEAR SURVEY DATA

The smears were counted in an NMC thin-window gas flow proportional counter. The average alpha background was 1 cpm whereas the average beta-gamma background was 53 cpm. This counting system exhibits 30% efficiency when used for U^{235} alphas and 45% efficiency when used for counting Sr^{90} betas. The results of the smear survey are as follows:

Attention: Mr. Robert E. Brinkman

Subject: Abandonment of a Facility Formerly Used for Nuclear Activities

Gentlemen:

Isotopes' Nuclear Systems Division has recently completed decontamination of the Martin Marietta Corporation's Radiochemistry Laboratory ("KJ" Building). This building was formerly used for those activities previously authorized under AEC Byproduct Material License No. 19-1398-33. Since we have no immediate need for this facility, we plan to relinquish control of the building so that it can be used by Martin Marietta for general use.

The resultant radioactive wastes have been packaged preparatory to shipment to an authorized disposal site and the results of the final radiological survey are transmitted herewith for your information.

Review of the attached survey data indicates that the proposed AEC guides governing the abandonment of nuclear facilities have been met; therefore, Isotopes, a Teledyne Company, hereby requests release of the subject facility for future public use. Please note that the request contained herein does not involve any change in the currently authorized uses described in Isotopes' AEC Byproduct Material License No. 19-1398-33.

We would appreciate receiving approval of this request at your earliest convenience. Please contact me directly on (301) 682-5800, Ext. 2513 or 7817 if I can be of further assistance in this matter.

Very truly yours,

Peter J. Knapp

MARTIN MARIETTA CORPORATION
MIDDLE RIVER, MARYLAND
RELEASE FOR PUBLIC USE OF A FACILITY FORMERLY USED FOR NUCLEAR ACTIVITIES BY MARTIN MARIETTA CORPORATION AND ISOTOPES, INC.

Late in 1968, Isotopes, Inc., (Isotopes) of Westwood, N.J. purchased the nuclear facilities of Martin Marietta Corporation (Martin) at Middle River, Maryland. Isotopes continued to conduct their nuclear activities in the building owned by the former licensee and Martin's licenses were transferred to Isotopes. Isotopes has discontinued their nuclear activities (under license 19-1398-33) in the radiochemistry laboratory ("KJ" Building), and has decontaminated the building. Martin plans to use "KJ" Building for non nuclear activities.

Recent radiological surveys of the "KJ" Building done by Isotopes, (under contract with Martin) indicate that the proposed AEC guides governing abandonment of nuclear facilities have been met. The survey results were transmitted to DML in two letters:

a. R. G. Macaulay, Martin Marietta, Corp., to Dr. J. A. Mc Bride, DML, letter dated June 11, 1969.

b. P. J. Knapp, Isotopes, Inc., to R. E. Brinkman, DML, letter dated June 17, 1969.

On June 27, 1969, R. Gilbert of CO:I visited the subject facility to confirm Isotopes' final survey of the "KJ" Building.

Survey instruments used by Gilbert included an Eberline E-120 type GM survey meter, range 0-20 mr/hr., window thickness $< 7.$ mg/cm^2, and an Eberline PAC-1SA alpha survey meter, 59 cm^2 window area.

The area surveyed is as sown on the drawing of the"KJ" Building which was submitted by Martin and Isotopes in their June, 1969 letters. Direct measurements for fixed alpha, beta, and gamma surface contamination were made at locations 2, 3, 5, 9, 13, 18, 20, 26, 32, 37, 40, 41, 45, 48, 49, 53and the sink behind location 37. No evidence of fixed contamination above instrument background was noted.

A1267

Smear surveys were made at location 49 and the filter box. No evidence of removable contamination was noted. Smear samples were monitored with the inspector's instruments.

Mr. P. J. Knapp of Isotopes., Inc., accompanied the inspector during the facility survey.

It is the inspector's opinion that the area can be redesignated as an unrestricted area.

The release of this building for non nuclear use does not involve any change in the currently authorized uses described in Isotopes' AEC byproduct license 19-1398-33.

H. W. Crocker
Senior Fuel Facilities Inspector

Attention: Mr. Peter J. Knapp
Licensing and Accountability
Representative

Gentlemen:

This is to acknowledge your letter of June 17, 1969, clarifying that Martin Marietta Corporation Building "KJ" is no longer needed for radioisotope operations under AEC byproduct material License No. 19-01398-33 and has been decontaminated for release. Your survey reports indicate that there is no need to maintain Building "KJ" as a restricted area nor to require a license of subsequent possessors of the building.

Sincerely,

Original signed by
Robert E. Brinkman

ISOTOPES
NUCLEAR SYSTEMS DIVISION
[illegible]
MIDDLE RIVER, MARYLAND [illegible]

15 August 1969

Refer to: PJK:1210:044

U. S. Atomic Energy Commission
Division of Materials Licensing
Washington, D. C. 20545

Attention: Mr. Robert Brinkman, Chief, Isotopes Branch

Subject: Notification of Isotopes' Nuclear Systems Division Move to New Facilities

Reference: (a) Title 10 Code of Federal Regulations, Parts 30.34C and 30.38

Gentlemen:

Isotopes' Nuclear Systems Division has recently completed arrangements to move to new quarters located at:

110 West Timonium Road
Timonium, Maryland 21093

It is presently anticipated that Isotopes will vacate the Middle River facilities by September 30, 1969 and restore operations at the new location on or about that same date.

In view of the foregoing, a thorough review of existing Byproduct Material License has been made. As a result of this review, we are requesting the following actions:

(1) Amendment of BPML No. 19-01398-01 reflecting the change in address. All other terms and conditions of this license to remain unchanged.

(2) BPML No. 19-01398-03 is to remain unchanged since there are no provisions in the new facility for this type irradiator; however, Isotopes is presently negotiating disposition of the Cobalt-60 gamma sources. As soon as disposal arrangements are completed, the license will be terminated. In any event, control of the facility will be retained in accordance with existing license requirements, utilizing Martin Marietta Corporation ADT Systems and Security personnel who are

A/272

3

instructed to notify Isotopes' Health Physics personnel in the event of an alarm. Since a large quantity of Cobalt-60 is presently stored in the facility as sealed sources under water, it has not been possible to perform a complete survey of the pool surfaces. There is always a possibility that contamination might be found on pool surfaces when the water is drained.

(3) Amendment of BPML No. 19-01398-09 reflecting the change in address. In addition, material control shall be accomplished in accordance with the statements and representations submitted February 3, 1969 supporting request for renewal of BPML No. 19-01398-01. All other terms and conditions of this license to remain unchanged.

(4) Termination of BPML No. 19-01398-19. All radioactive materials formerly possessed under this license have been disposed of in compliance with the provisions of 10 CFR 20 by transfer to a company authorized to receive them.

(5) Termination of BPML No. 19-01398-20. All radioactive materials formerly possessed under this license have been disposed of in compliance with the provisions of 10 CFR 20 by transfer to a licensed waste disposal service.

(6) Amendment of BPML No. 19-01398-21 reflecting the change in address. All other terms and conditions of this license to remain unchanged with the exception of the following:

(a) Amend license condition 16 by deleting from the referenced letter dated June 29, 1969, reference to the following letters:

1. Two letters each dated August 10, 1962.
2. One letter dated July 30, 1963.
3. One letter dated January 11, 1965.

(b) Access to the Timonium location is controlled by personnel during normal working hours, and the plant is locked at all other times.

(7) Termination of BPML No. 19-01398-23. All radioactive materials formerly possessed under this license have been disposed of in compliance with the provisions of 10 CFR 20 by transfer to a licensed waste disposal service.

(8) Termination of BPML No. 19-01398-25. All radioactive material formerly possessed under this license have been disposed of in compliance with the provisions of 10 CFR 20 by transfer to a licensed waste disposal service.

12038
12039

(9) Amendment of BPML No. 19-01398-31 reflecting the change in address. All other terms and conditions of this license to remain unchanged.

(10) Termination of BPML No. 19-01398-33. All radioactive materials formerly possessed under this license have been disposed of in compliance with the provisions of 10 CFR 20 by transfer to an authorized waste disposal service.

(11) Amendment of BPML No. 19-01398-34 reflecting the change in address. All other terms and conditions of this license to remain unchanged.

(12) Amendment of BPML No. 19-01398-36 reflecting the change in address and also modifying the authorized use for storage only. Presently the only inventory of H^3 (15 C_i) is that which is contained inside the accelerator system, ion pump and target cavity. Isotopes is presently negotiating disposition of this neutron generator. As soon as disposal arrangements are completed, we intend to terminate this license. In any event, control of this unit while in our possession will be retained in accordance with sound radiological practices consistent with the degree of hazard involved.

In order that we achieve our scheduled goal to vacate occupancy of the Middle River Facility by September 30, 1969, we solicit your prompt action in reviewing and granting the requested license changes described herein. If we can be of any assistance to you in this matter, please call on us directly.

Thank you again for your usual assistance and expeditious licensing efforts.

Very truly yours,

Peter J. Knapp
Licensing and Accountability
Representative

NRC Reviewer:	David F. Limroth, Stephen W. Holmes		

Review Abstract: License No. SNM-00053 authorized the possession of special nuclear material in Building D at Middle River, Maryland and at Timonium, Maryland. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces. The building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on November 3, 1994 indicate that the site is suitable for unrestricted use.

Licensee, NRC, and Maryland State surveys indicate that the Timonium site is suitable for unrestricted use.

Recommendations: NONE

Summary: License No. SNM-00053 authorized possession and use of up to 1,000 kilograms of uranium enriched in U-235 as UO_2 and metal and 160 grams of plutonium in the form of a plutonium-beryllium source. Licensed activities included fuel element development and fabrication at the Middle River facility. On September 23, 1969 License No. SNM-01150 was issued pursuant to an amendment to License No. SNM-00053 to permit the transfer and use of up to 100 grams of U-235, at any enrichment and in any chemical form, for research and development activity, and 171 grams of Pu-235 for neutron and alpha instrument calibration sources, from the Middle River facility to the Timonium facility. Concurrently, SNM-00053 was amended in its entirety to authorize the storage of U-235 in the form of contamination in Building D at Middle River. License No. SNM-00053 (Teledyne-Isotopes) was terminated May 26, 1970. There is no termination or confirmatory survey for License No. SNM-01150.

A/291

March 10, 1995

Information from various docket files indicates that a variety of activities with large amounts of byproduct, source, and special nuclear material were authorized at Building D at the Middle River facility. Activities with licensed material at Building D ceased prior to 1970. License No. SNM-1192 was issued to Martin-Marietta on May 22, 1970 and authorized the decontamination of the Martin-Marietta, Middle River, Maryland facility. License No. SNM-1192 has the same Docket No. (70-58) as License No. SNM-53 and all records for License Nos. SNM-1192 and SNM-01150 are contained in the docket file for License No. SNM-53. Apparently only Building D was decontaminated under License No. SNM-1192. Building D was decontaminated from June to September 1970 and a final survey report provided to the AEC with a letter dated September 22, 1970. The final survey report states that a total of 29 μCi of U-235 remained in five drains which were to be were sealed with concrete; one small area of fixed Sr-90 contamination (0.5 mrad/hr) also remained. The building was demolished after the survey, leaving only the concrete pad. Region I staff reviewed the available documentation in 1982 and concluded in Combined Inspection Report Nos. 40-3296/82-01 and 40-2308/82-01 that the site met NRC criteria for unrestricted use.

An NRC site visit and survey was performed on November 3, 1994 to assure that the site meets current NRC guidelines for release for unrestricted use. Buildings C and D at the Middle River facility and Buildings KJ and KC at the Martin State Airport were surveyed. The results of the surveys indicate no radiation or contamination levels above background in any of the buildings surveyed, including the concrete pad remaining from Building D. The contaminated drains discussed in the final survey report regarding Building D were not located, although a number of openings in the pad which had been filled with concrete were identified. Therefore, it seems apparent that the drains identified as contaminated during the final survey were plugged with concrete, as proposed by the licensee. Based on the fact that no radiation or contamination levels above background were detected, it seems unlikely that U-235 contamination in the drains, if present, is a significant hazard. Therefore, the site is suitable for unrestricted use.

Licensee letter dated March 25, 1975 documents a survey of the Timonium site consisting of 67 wipes and a portable instrument alpha/beta/gamma survey of "all areas that had been subject to use of radioactive materials" which identified no residual contamination. An NRC letter dated April 15, 1975 of an inspection to confirm disposition of license material under License No. SNM-0849 and an examination of the licensees contamination survey reported that "no items of noncompliance were observed". The State of Maryland terminated License MD-05-014-01 (formerly USNRC License No. 19-01398-34) covering the whole site after performing a confirmatory survey on July 19, 1993 of the licensee's termination survey of June 8 and 9, 1993. The site is suitable for unrestricted use.

There is no termination or confirmatory survey under this license number. Licensee, NRC, and Maryland State surveys indicate that the Timonium site is suitable for unrestricted use.		

Recommendations: NONE

Summary: License No. SNM-01150 was issued September 23, 1969 pursuant to an amendment to License No. SNM-00053 to permit the transfer and use of up to 100 grams of U-235, at any enrichment and in any chemical form, for research and development activity, and 171 grams of Pu-235 for neutron and alpha instrument calibration sources, from the Middle River facility to the Timonium facility.

The license information for License No. SNM-01150 is docketed with License No. SNM-00053. There is no termination or confirmatory survey for this license.

Licensee letter dated March 25, 1975 documents a termination survey of the Timonium site consisting of 67 wipes and a portable instrument alpha/beta/gamma survey of "all areas that had been subject to use of radioactive materials" which identified no residual contamination. An NRC letter dated April 15, 1975 of an inspection to confirm disposition of license material under license SNM-0849 and an examination of the licensee's contamination survey reported that "no items of noncompliance were observed". The State of Maryland terminated License No. MD-05-014-01 (formerly USNRC License No. 19-01398-34), covering the whole site, after performing a confirmatory survey on July 19, 1993 of the licensee's termination survey of June 8 and 9, 1993 which encompassed the entire facility. The site is suitable for unrestricted use.

NRC Reviewer:	David F. Limroth, Stephan W. Holmes		
Review Abstract:	License No. SNM-01192 was issued for the decontamination of Building D at the Middle River facility. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces. The building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on November 3, 1994 indicate that the site is suitable for unrestricted use.		
Recommendations:	None.		

Summary: License No. SNM-01192 was issued for the decontamination of Building D at the Middle River (Chesapeake Park) facility. Operations authorized under various licenses had been conducted at this location.

Information from various docket files indicates that a variety of activities with large amounts of byproduct, source, and special nuclear material were authorized at Building D at the Middle River facility. Activities with licensed material at Building D ceased prior to 1970. License No. SNM-1192 was issued to Martin-Marietta on May 22, 1970 and authorized the decontamination of the Martin-Marietta, Middle River, Maryland facility. License No. SNM-1192 has the same Docket No. (70-58) as License No. SNM-53 and all records for License No. SNM-1192 are contained in the docket file for License No. SNM-53. Apparently only Building D was decontaminated under License No. SNM-1192. Building D was decontaminated from June to September 1970 and a final survey report provided to the AEC with a letter dated September 22, 1970. The final survey report states that a total of 29 μCi of U-235 remained in five drains which were to be were sealed with concrete; one small area of fixed Sr-90 contamination (0.5 mrad/hr) also remained. The building was demolished after the survey, leaving only the concrete pad. Region I staff reviewed the available documentation in 1982 and concluded in Combined Inspection Report Nos. 40-3296/82-01 and 40-2308/82-01 that the site met NRC criteria for unrestricted use.

An NRC site visit and survey was performed on November 3, 1994 to assure that the

site meets current NRC guidelines for release for unrestricted use. Buildings C and D at the Middle River facility and Buildings KJ and KC at the Martin State Airport were surveyed. The results of the surveys indicate no radiation or contamination levels above background in any of the buildings surveyed, including the concrete pad remaining from Building D. The contaminated drains discussed in the final survey report regarding Building D were not located, although a number of openings in the pad which had been filled with concrete were identified. Therefore, it seems apparent that the drains identified as contaminated during the final survey were plugged with concrete, as proposed by the licensee. Based on the fact that no radiation or contamination levels above background were detected, it seems unlikely that U-235 contamination in the drains, if present, is a significant hazard. Therefore, the site is suitable for unrestricted use.

RE: Radioactive Material License Number MD-05-014-01

Dear Mr. Vogt:

On July 19, 1993 the Maryland Department of the Environment's Radiological Health Program completed a confirmatory radiological close-out survey of your facility which is authorized under the above referenced license and located at 110 W. Timonium Road in Timonium, Maryland.

Results of this survey indicate that this facility meets the Department's requirements for future unrestricted use. Should there be any questions concerning this letter, please contact Mr. Raymond Manley or me, at (410) 631-3301.

Sincerely,

Raymond E Manley fm

RE: Results of Radiological Survey of Teledyne Facility
Located at 110 W. Timonium Road, Timonium, MD

Dear Mr. Vogt:

At the request of your firm, I performed a third party independent radiological survey of the Teledyne facility located at 110 W. Timonium Road, Timonium, MD on June 8th and 9th, 1993.

The extensive direct radiation measurements made at the facility with field instrumentation and analysis of the numerous swipe samples by sensitive laboratory instrumentation confirm that no licensed radioactive materials are detectable above the ambient background level. This being the case, the facility has met the free release criteria as described in NRC Regulatory Guide 1.86, Table I by a wide margin of safety and is therefor suitable for occupation by another leaseholder.

This facility close-out survey was authorized by Teledyne Energy Systems under purchase order 28900 dated May 27, 1993.

All instrumentation used was calibrated under the program authorized by the State of Maryland Department of the Environment license # MD-33-021-01.

I hereby state that I am a Heath Physicist Certified by the American Board of Health Physics with extensive experience in the area of industrial facility contamination assessment and decontamination and am therefor adequately qualified to perform this building close-out survey.

Sincerely,

Joseph W Moon, CHP

CLOSE-OUT RADIOLOGICAL SURVEY OF THE TELEDYNE ENERGY SYSTEMS FACILITY AT 110 W. TIMONIUM ROAD, TIMONIUM, MD 21093

1.0 HISTORICAL PERSPECTIVE AND APPROACH

Only two radionuclides were historically present at the facility. These radionuclides were strontium-90 (Sr-90) and plutonium-238 (Pu-238). Sr-90 was received at the facility already loaded into thermo-electric devices to be performance tested. The actual sealed sources in these devices were never removed from the devices. Pu-238 was received only as sealed sources under Department of Energy (DOE) authorization for loading into thermo-electric devices. The loading of these sources was performed within a glove box containment structure with full radiological control practices applied. At the time these operations were terminated, the containment was shipped to Mound Laboratory. The former Pu-238 containment filtration/exhaust system was renovated to fit a new "glove box" when the old containment structure was removed. At that time all filtration elements were exchanged. The areas of the building where Pu-238 activities had been conducted were surveyed by Teledyne Energy Systems personnel and were found to be free of contamination. All of the thermo-electric devices of both types have been transferred to end users and none remain at the facility.

The licensed radioactive material retained on site consists of sealed sources used for the calibration of radiological survey instrumentation, and a variety of check sources used for the same purpose under the existing license. The integrity of these sources is assured under the licensee's source inventory control program and all of these sources will be either disposed of or transferred to another licensee prior to vacating the current building. With regard to the remaining licensed sources, the scope of this survey has only addressed the possibility of facility contamination around the source storage locations as identified by the facility Radiation Safety Officer. There are various articles (2% thoria welding rods and items composed of magnesium-thoria metal) at the facility containing various amounts of naturally occurring thorium that is not subject to licensed regulation (< 5% thoria) but are nevertheless radioactive. Each of these articles has been identified and will be removed prior to vacating the premises. The close-out survey verified that each of these articles effectively contained the naturally occurring activity such that there is not a possibility that residual radioactive material will remain in the facility when these articles are removed.

It was impractical to dismantle the piping of the old Pu-238 containment exhaust system as it was still in use at the time of the survey. The internal surfaces of this piping were not included in the scope of this survey. Although unlikely considering that only sealed sources were handled, the internal surfaces of this piping below the High Efficiency Particulate Absorber (HEPA) filters are still potentially contaminated. These sections of the piping will be isolated disassembled and removed prior to vacating the premises.

The approach taken for this close-out survey did not assume credit for anticipated conditions but was conducted as though contamination was expected to be present at some detectable level. The scope of the final close-out survey encompassed the entire facility and not just those areas where radioactive sources were handled.

2.0 SELECTION OF SURVEY INSTRUMENTATION

The instrumentation used for this survey was selected specifically for its capacity to detect the radionuclides historically handled at the facility (Pu-238, and Sr-90) but was also suitable to detect naturally occurring thoria compounds. All instrumentation used was calibrated under the program authorized by the State of Maryland Department of the Environment license # MD-33-021-01. Each field survey instrument was source checked both prior to and following use to assure they were properly functioning during the survey. Background readings for each of the instruments used were also determined and recorded. The following is a listing of the field survey instrumentation used to perform this survey.

- Alpha: Ludlum 50 cm^2 zinc-sulfide detector (Model 43-1 Serial Number 020791) attached to a Ludlum count rate meter (Model 3 Serial Number 91842). Calibration Date: 6/3/93
  Efficiency for Pu-238 5.5 MeV alpha - 33% determined by calibration with Am-241 (5.49 MeV)
  Sensitivity: 60 dpm/100 cm^2 fixed contamination
  10 dpm/100 cm^2 loose surface on 300 cm^2 swipe
  Reg. Guide 1.86 Criteria: 200 dpm/100 cm^2 ave. fixed
  300 dpm/100 cm^2 max. fixed
  20 dpm/100 cm^2 loose surface

- Beta/Gamma Bicron Surveyor count rate meter (Serial Number AHS-A198A) with standard 17 cm^2 GM Pancake Probe detector (Serial Number 2081)
  Calibration Date: 5/18/93
  Efficiency for Sr/Y-90 Beta particles - 46%
  Sensitivity (@ equilibrium): 10 dpm/ probe area (60 dpm/100 cm^2)
  Reg. Guide 1.86 Criteria: 5000 dpm/100 cm^2 fixed
  1000 dpm/100 cm^2 loose surface

- Gamma Background Victoreen Pressurized Ion Chamber (Model 450 P/Serial Number 583)
  Calibration Date: 2/24/93
  Sensitivity: 10 μR/hr nominal
  Reg. Guide 1.86 Criteria: None

Remote instrumentation used for swipe analysis in off site laboratory

(RSO, Inc., Laurel, MD)

- Liquid Scintillation counter set-up for Am-241 alpha Beckman LS-6000
  Sensitivity: 50 dpm/swipe area

- Gas Flow Proportional counter (Baird Atomic Model SSC-3)
  10 minute counts (nominal efficiency 46% for Thorium-230 alpha 2 pi geometry)
  Sensitivity: < 10 dpm/swipe area

3.0 SURVEY PLAN

The basis of the survey plan was determined by the nature of operations at the facility. A semi-biased survey was warranted since only sealed sources were handled at the facility with full source inventory and contamination controls in place during operations.

Prior to the initiation of the survey, instrument operability checks (e.g. battery checks and source checks where appropriate) were performed and instrument background readings were made in an area not suspected to be affected by former facility operations.

The criteria used for determining suitability for unrestricted use is that specified in Nuclear Regulatory Commission Regulatory Guide 1.86 unless otherwise specified by the concerned regulatory authorities.

3.1 Preliminary Survey

A preliminary survey was performed and was focused on the areas most likely to contain radioactive contamination from licensed operations conducted at the facility. The purpose of this focus was to determine at an early stage of the survey work the worse case radiological conditions that would be encountered at the facility should any residual radioactivity be detected. The preliminary survey entailed a detailed survey of seven designated "Radioactive Material areas" areas (R.A.M.) identified by the facility Radiation Safety Officer (Mr. John Vogt). In addition, the scope of the preliminary survey included a moderately conservative assessment of the entire former source security control area (the effective Radiological Control Area).

The nature of the seven designated R.A.M. was described as follows:

Area 1 White Room - A room used for the preparation of device subassemblies. Some radioactive Material is known to have been in this room and therefor it was designated as a primary survey area.

Area 2 — Pu-238 Device Assembly Area (Submarine Room) - The Pu-238 sealed sources were loaded into the thermo electric devices inside a containment structure known as the "submarine" located in the room. The containment was maintained under negative pressure by a ventilation system having HEPA filters in line prior to the roof discharge vents. Access and contamination controls were in place during these operations.

Area 3 — Facility Security Vault - The vault located in the administrative area contains a triply contained vessel containing approximately 740 grams of thoria. The container was opened and the integrity of the internal packaging was verified. The area was surveyed solely due to the presence of this material currently in the vault.

Area 4 — Pu-238 Source Storage Area - This area was controlled under heavy security during operations and contained all Pu-238 sealed sources not yet assembled into devices. The area is currently in use as a high security storage area and also contains the 1 mCi Radium source used for instrument calibration.

Area 5 — Pu-238 Source Testing and Measurement Area - This area is basically a floor space designated for the use of testing and measurement of the Assembled devices. The devices were lifted from a pedestal by and overhead crane where they were tested and measured while suspended above the floor.

Area 6 — Strontium Device Testing Area - This area is a sunken truck bay with a roll-up door access to the east end of the facility. The assembled Strontium devices were placed in the truck bay, tested and then repackaged for shipment all in the same area. No strontium containing devices were ever disassembled at the facility.

Area 7 — Source Storage Locker - This area is a locked file cabinet containing various check sources for use with the facility radiation detection instrumentation.

If the results of the preliminary detailed surveys in the seven designated R.A.M. areas and the conservative survey of the remainder of the former source security area did not indicate the presence of residual radioactive material, there would be little probability that the rest of the facility would have been adversely affected by the licensed operations. The survey plan for the rest of the facility would only be cursory in nature with several direct measurements and smears being assessed by field counting in each room or general activity area. The measurements taken in these areas would be focused on high traffic areas where it is likely that contamination, if spread to other sections of the facility, would be present in detectable quantities (see section on survey techniques).

The general plan for those areas designated as RAM locations include an initial gamma background rate measurement followed by local instrument background determinations for the other survey instruments. A detector window integrity test for the zinc sulfide α instrument would the be performed by holding the detector up to a source of fluorescent light. An increase in the background rate would indicate a loss of window integrity and the use of the instrument.

Randomly selected locations on horizontal and vertical surfaces in the rooms with areas of 100 cm^2 would then be measured directly with field instrumentation. At each location where the initial direct measurement is in excess of the background level, the measurement will be recorded. A swipe of each area would then be made to assess the levels of loose contamination on the surface. These swipes would be set aside for a period of 4 hours to allow for the decay of naturally occurring radionuclides (e.g. Radon progeny). After the decay period each swipe would be measured for alpha and beta contamination in a location that is not expected to have been affected by facility operations. A direct measurement of the surface would be made after the swipe was obtained to assess the level of fixed contamination at the location. If the results of any of the surveys presented evidence of unanticipated contamination above the surface contamination release guidelines (NRC Reg. Guide 1.86 criteria) at any of the measured locations, this would be an indication that further assessment would be required to allow a statistical characterization of the areas containing detectable activity. Swipes of the areas would be counted in either a proportional counter (set up for the detection of alpha particle emissions after a minimum decay period of 24 hours) or a liquid scintillation counter set up for the measurement of Pu-238 α emissions. Some portion of the population of swipes taken would be assessed by the proportional counter and some taken near the same locations will be assessed by liquid scintillation counting as a qualitative cross check of instrument reliability. Whereas the sensitivity of the hand held α detector is greater than that of either of the two laboratory instruments, the measurement of large area swipes (not a suitable media for assessment in the lab counters) using this field instrument was considered to be an acceptable alternative to exhaustive swipe collection and analysis if no measurable α activity could be found by direct measurements. Even in the case that no detectable activity would be discovered by field instrumentation on large area swipes, a suitable number of swipes will be analyzed by the laboratory instrumentation to document the status of the targeted R.A.M. areas.

If any of the "RAM" areas were found to be contaminated, a full survey would be performed to characterize the area and any affected adjacent areas until the full extent of the contamination could be determined. If no detectable contamination was found in the "RAM" areas the survey of the adjacent room will focus on common traffic patterns for personnel carrying radioactive material.

Following the surveys instrument operability checks will be repeated to demonstrate operability at the end of the survey.

3.2 Contingencies and Extended Survey Work

The nature and extent of any additional survey work required (characterization) would only be apparent when the results of the preliminary survey are known.

If long-lived alpha contamination was detected at the facility, provisions for the assessment of samples by alpha spectroscopy could be made to positively identify the contaminant as Plutonium-238.

Extended survey work necessary for the characterization of the contamination in the facility would be performed along the guidelines provided by the Nuclear Regulatory Commission. This type of survey was recommended (NUREG/CR 2082 1981) to document that a facility can be released to perform operations not involving the use of radioactive material and would require a much more extensive framework of area mapping and characterization. This extensive type of survey is meant to be used to document the effectiveness of a decontamination effort when it is known that a facility was at one time contaminated. The focus of the preliminary survey is to demonstrate that the facility has never been contaminated with the material it was licensed to handle.

Areas above any suspended ceilings and inside ventilation duct work would need to be assessed should any unanticipated contamination be found. Access to these areas and other normally inaccessible areas of the facility would be required in this unlikely circumstance.

4.0 SURVEY RESULTS AND SPECIALIZED SURVEY TECHNIQUES

The extensive direct radiation measurements made at the facility with field instrumentation and analysis of the numerous swipe samples by sensitive laboratory instrumentation confirm that no licensed radioactive materials are detectable above the ambient background level. This being the case, the facility has met the free release criteria as described in NRC Regulatory Guide 1.86, Table I by a wide margin of safety and is therefore suitable for occupation by another leaseholder.

Standard radiological survey techniques were employed to avoid cross contamination of swipe samples and to make direct measurements of surface activity (< 0.5" from surface without contact). Initially, small area tack cloth swipes (300 cm^2) of the targeted R.A.M. were taken and measured for both α and β/γ with the field instrumentation to assess the status of an area. These small area swipes would be appropriate in the event an area was found to be contaminated requiring detailed characterization of the distribution of activity on room surfaces. When no detectable radioactive material was found by direct measurements or on the small area tack cloth swipes, large area swipes (> 500 cm^2) were taken of the areas. In all cases these large area swipes were also found to be free of any detectable radioactive material.

The process of collection and analysis of large numbers of swipes (for area characterization) on media suitable for analysis by proportional counter and by liquid scintillation counting in this situation seemed pointless. A suitable number of these type of swipes were then taken in each area to verify the findings of the field instrument assessments and to provide a representative number of measurements of each area to allow an assessment of the radiological conditions in the unlikely event that the field instrument readings were faulty. All of these swipe samples were also measured for detectable α and ß/γ activity prior to being sent to the laboratory for analysis. None of these swipe samples contained any activity detectable with the field instrumentation.

Other survey techniques employed for this survey involved measurements of locations in the facility where radioactive materials if present would have been concentrated. Specifically, drain traps, subfloor piping recesses, surfaces above suspended ceilings, room air exhaust duct work and associated air filtration support members were surveyed. In addition, work station vacuum cleaners, grime accumulations on old fan blade shields, and fume hood exhaust plenums were measured as areas where if loose surface contamination by licensed radioactive material had been present at any time it would be unlikely that these areas would have been affected by subsequent decontamination efforts. No evidence of residual licensed radioactive material was found in any of these locations

The majority of the floor surface of the former source security area including the workshop, shipping and receiving areas, tool cribs and material storage areas was unsealed concrete. Tack cloth was used to acquire large area swipes on these surfaces. No detectable activity either α or ß/γ were detected on any of these swipes. On this type of surface, loose surface activity, if present, would have accumulated in corners and in cracks and crevices in the flooring. Extraction of some of this material from crevices and direct measurement of this material with field instruments would reveal the presence of historical facility contamination if it had been present. No evidence of licensed radioactive material was found in the crud residue excavated from these recesses or on any of the direct measurements made along these crevices.

The horizontal and vertical surfaces of all laboratories where radioactive material was present during facility operations were assessed by direct measurements and by swipe samples for the presence of residual activity. Where new surfaces had been applied since the cessation of radiological operations , the original surfaces were sought out and assessed. No evidence of residual licensed radioactive material was found in any of these measurements.

In the administrative areas of the facility, measurements of large area tack cloth swipes taken along major foot traffic patterns and in the relatively inaccessible areas below the stairwells did not indicate the presence of any residual contamination. Direct measurements of the areas along the bases of the walls and in corners where routine cleaning efforts were noticeably ineffective were also found to be free of residual

radioactive material. In areas where carpeting was installed, direct measurements of high traffic areas indicated by carpet wear, accumulations of sticky grime embedded into carpet fibers, and lower door closure recesses were assessed with no positive indications found.

None of the direct measurements of gamma background made with the pressurized ion chamber in any part of the facility (administrative or security areas) were in excess of 25 μR/hr with most of the measurements falling within the 10 to 20 μR/hr range.

The attached survey maps detail the survey work done in the six primary designated R.A.M. areas. On the maps of areas 1 and 2, the locations where the small area tack cloth wipes were taken are not indicated as they would unnecessarily clutter the diagram and interfere with the documentation of the locations where the proportional and liquid scintillation counter swipes were taken. No small area tack cloth swipes were taken in area 5 where large area swipes were used for the initial assessment. No map is attached for area 7 due to the small area involved. No fixed or loose surface activity was detected on any of the surfaces adjacent to this area (current source storage locker).

RSO, Inc.

Radiation Service Organization

June 11, 1993

Joe Moon
J. Stewart Bland Associates, Inc.
133 Defense Highway, Suite 208
Annapolis, MD 21401

Dear Mr. Moon,

Thank you for choosing RSO, Inc. to provide you with radioanalytical services. The results for the 110 samples you recently delivered to our laboratory are summarized below.

The 100 paper wipes were analyzed using a Beckman LS6000 Liquid Scintillation Counter (LSC). The counter was properly calibrated and standardized to identify the alpha emissions of Pu-238. The minimum detectable activity for this analysis was 50 disintegrations per minute (DPM). None of the 100 wipes exceeded 50 DPM.

The 10 adhesive backed wipes were analyzed using a Baird-Atomic Gas Flow Proportional Counter (GFPC). This analysis is not isotope specific, the measurement is for gross alpha activity only. The MDA for this instrument was 2.8 DPM. None of the 10 wipes exceeded 2.8 DPM.

If you have any questions about this report or our analysis protocol, please call me. Thank you again for choosing RSO, Inc.

U-235	LOOSE	100.00	GR	~~0.0~~
PU-BE PELLETS	SEALED	159.94	GR	~~0.0~~
SEALED PU-239 SOURCE	SEALED	10.41	GR	0.0

INITIAL SITE SCORE, based on LOOSE material possession limits: 5.0
INITIAL SCORE of the SEALED sources is: 34.57
FINAL SCORE of the SEALED sources is: 0.00

---

1. License included both sealed and loose materials

2. There was at least one sealed source authorized on this license which was not accounted for by the disposition information.

3. Sealed sources or shielding on the license contained large amounts of extremely hazardous materials

4. There was one identifiable site with this license.

5. FIRST SITE: Some likelihood that building onsite could have been left with contamination. Score=score*1.0

6. FIRST SITE: There was NO verifiable decontamination of the site at closeout. Score=score*1.2

7. FIRST SITE: No closeout survey was conducted for this site. Score=score*2.

8. FIRST SITE: There was NOT an NRC FINAL INSPECTION of the facility.

9. FIRST SITE: There was no evidence of releases at this site. Score not changed.

10. Information insufficient to judge frequency of turnover for operation Score not changed

11. FIRST SITE: There was significant generation of waste material in routine cleanup of facility. Score=score*1.5

12. FIRST SITE: Possible inappropriate disposal or abandonment of contaminated material from cleanup. Score=score*1.2

13. FIRST SITE: There was either no documentation of materials disposition or the documentation was inadequate. Score=score*1.2

14. FIRST SITE: There was no available information indicating onsite disposal of material or waste at the site. Score not changed

15. FIRST SITE: There were no verifiable intermediate decontamination efforts. No change in score

16. Class 1 category of license is due primarily to supporting info which indicates that contamination of the site may be present

RE: Radioactive Material License Number MD-05-014-01

Dear Mr. Vogt:

On July 19, 1993 the Maryland Department of the Environment's Radiological Health Program completed a confirmatory radiological close-out survey of your facility which is authorized under the above referenced license and located at 110 W. Timonium Road in Timonium, Maryland.

Results of this survey indicate that this facility meets the Department's requirements for future unrestricted use. Should there be any questions concerning this letter, please contact Mr. Raymond Manley or me, at (410) 631-3301.

Sincerely,

Raymond E Manley Jr

RE: Results of Radiological Survey of Teledyne Facility
Located at 110 W. Timonium Road, Timonium, MD

Dear Mr. Vogt:

Please find enclosed the report on the results of the radiological survey I performed at your facility on June 8th and 9th, 1993. If you require any editorial changes to the report please let me know as soon as possible.

As I mentioned during our telephone conversation, the issue of the need for a Maryland license to perform surveys appears to be resolved. If you have any questions about the report please do not hesitate to call me. I can be reached at (215) 873-9464. Thank you again for choosing JSB Associates for your radiological consulting needs.

Sincerely,

Joseph W Moon, CHP

RE: Results of Radiological Survey of Teledyne Facility
Located at 110 W. Timonium Road, Timonium, MD

Dear Mr. Vogt:

At the request of your firm, I performed a third party independent radiological survey of the Teledyne facility located at 110 W. Timonium Road, Timonium, MD on June 8th and 9th, 1993.

The extensive direct radiation measurements made at the facility with field instrumentation and analysis of the numerous swipe samples by sensitive laboratory instrumentation confirm that no licensed radioactive materials are detectable above the ambient background level. This being the case, the facility has met the free release criteria as described in NRC Regulatory Guide 1.86, Table I by a wide margin of safety and is therefore suitable for occupation by another leaseholder.

This facility close-out survey was authorized by Teledyne Energy Systems under purchase order 28900 dated May 27, 1993.

All instrumentation used was calibrated under the program authorized by the State of Maryland Department of the Environment license # MD-33-021-01.

I hereby state that I am a Heath Physicist Certified by the American Board of Health Physics with extensive experience in the area of industrial facility contamination assessment and decontamination and am therefor adequately qualified to perform this building close-out survey.

Sincerely,

Joseph W Moon, CHP

June 30, 1993

CLOSE-OUT RADIOLOGICAL SURVEY OF THE TELEDYNE ENERGY SYSTEMS FACILITY AT 110 W. TIMONIUM ROAD, TIMONIUM, MD 21093

1.0 HISTORICAL PERSPECTIVE AND APPROACH

Only two radionuclides were historically present at the facility. These radionuclides were strontium-90 (Sr-90) and plutonium-238 (Pu-238). Sr-90 was received at the facility already loaded into thermo-electric devices to be performance tested. The actual sealed sources in these devices were never removed from the devices. Pu-238 was received only as sealed sources under Department of Energy (DOE) authorization for loading into thermo-electric devices. The loading of these sources was performed within a glove box containment structure with full radiological control practices applied. At the time these operations were terminated, the containment was shipped to Mound Laboratory. The former Pu-238 containment filtration/exhaust system was renovated to fit a new "glove box" when the old containment structure was removed. At that time all filtration elements were exchanged. The areas of the building where Pu-238 activities had been conducted were surveyed by Teledyne Energy Systems personnel and were found to be free of contamination. All of the thermo-electric devices of both types have been transferred to end users and none remain at the facility.

The licensed radioactive material retained on site consists of sealed sources used for the calibration of radiological survey instrumentation, and a variety of check sources used for the same purpose under the existing license. The integrity of these sources is assured under the licensee's source inventory control program and all of these sources will be either disposed of or transferred to another licensee prior to vacating the current building. With regard to the remaining licensed sources, the scope of this survey has only addressed the possibility of facility contamination around the source storage locations as identified by the facility Radiation Safety Officer. There are various articles (2% thoria welding rods and items composed of magnesium-thoria metal) at the facility containing various amounts of naturally occurring thorium that is not subject to licensed regulation (< 5% thoria) but are nevertheless radioactive. Each of these articles has been identified and will be removed prior to vacating the premises. The close-out survey verified that each of these articles effectively contained the naturally occurring activity such that there is not a possibility that residual radioactive material will remain in the facility when these articles are removed.

It was impractical to dismantle the piping of the old Pu-238 containment exhaust system as it was still in use at the time of the survey. The internal surfaces of this piping were not included in the scope of this survey. Although unlikely considering that only sealed sources were handled, the internal surfaces of this piping below the High Efficiency Particulate Absorber (HEPA) filters are still potentially contaminated. These sections of the piping will be isolated disassembled and removed prior to vacating the premises.

The approach taken for this close-out survey did not assume credit for anticipated conditions but was conducted as though contamination was expected to be present at some detectable level. The scope of the final close-out survey encompassed the entire facility and not just those areas where radioactive sources were handled.

2.0 SELECTION OF SURVEY INSTRUMENTATION

The instrumentation used for this survey was selected specifically for its capacity to detect the radionuclides historically handled at the facility (Pu-238, and Sr-90) but was also suitable to detect naturally occurring thoria compounds. All instrumentation used was calibrated under the program authorized by the State of Maryland Department of the Environment license # MD-33-021-01. Each field survey instrument was source checked both prior to and following use to assure they were properly functioning during the survey. Background readings for each of the instruments used were also determined and recorded. The following is a listing of the field survey instrumentation used to perform this survey.

- Alpha: Ludlum 50 cm^2 zinc-sulfide detector (Model 43-1 Serial Number 020791) attached to a Ludlum count rate meter (Model 3 Serial Number 91842). Calibration Date: 6/3/93
  Efficiency for Pu-238 5.5 MeV alpha - 33% determined by calibration with Am-241 (5.49 MeV)
  Sensitivity: 60 dpm/100 cm^2 fixed contamination
  10 dpm/100 cm^2 loose surface on 300 cm^2 swipe
  Reg. Guide 1.86 Criteria: 200 dpm/100 cm^2 ave. fixed
  300 dpm/100 cm^2 max. fixed
  20 dpm/100 cm^2 loose surface

- Beta/Gamma Bicron Surveyor count rate meter (Serial Number AHS-A198A) with standard 17 cm^2 GM Pancake Probe detector (Serial Number 2081)
  Calibration Date: 5/18/93
  Efficiency for Sr/Y-90 Beta particles - 46%
  Sensitivity (@ equilibrium): 10 dpm/ probe area (60 dpm/100 cm^2)
  Reg. Guide 1.86 Criteria: 5000 dpm/100 cm^2 fixed
  1000 dpm/100 cm^2 loose surface

- Gamma Background Victoreen Pressurized Ion Chamber (Model 450 P/Serial Number 583)
  Calibration Date: 2/24/93
  Sensitivity: 10 μR/hr nominal
  Reg. Guide 1.86 Criteria: None

Remote instrumentation used for swipe analysis in off site laboratory

(RSO, Inc., Laurel, MD)

- Liquid Scintillation counter set-up for Am-241 alpha Beckman LS-6000
  Sensitivity: 50 dpm/swipe area

- Gas Flow Proportional counter (Baird Atomic Model SSC-3)
  10 minute counts (nominal efficiency 46% for Thorium-230 alpha 2 pi geometry)
  Sensitivity: < 10 dpm/swipe area

3.0 SURVEY PLAN

The basis of the survey plan was determined by the nature of operations at the facility. A semi-biased survey was warranted since only sealed sources were handled at the facility with full source inventory and contamination controls in place during operations.

Prior to the initiation of the survey, instrument operability checks (e.g. battery checks and source checks where appropriate) were performed and instrument background readings were made in an area not suspected to be affected by former facility operations.

The criteria used for determining suitability for unrestricted use is that specified in Nuclear Regulatory Commission Regulatory Guide 1.86 unless otherwise specified by the concerned regulatory authorities.

3.1 Preliminary Survey

A preliminary survey was performed and was focused on the areas most likely to contain radioactive contamination from licensed operations conducted at the facility. The purpose of this focus was to determine at an early stage of the survey work the worse case radiological conditions that would be encountered at the facility should any residual radioactivity be detected. The preliminary survey entailed a detailed survey of seven designated "Radioactive Material areas" areas (R.A.M.) identified by the facility Radiation Safety Officer (Mr. John Vogt). In addition, the scope of the preliminary survey included a moderately conservative assessment of the entire former source security control area (the effective Radiological Control Area).

The nature of the seven designated R.A.M. was described as follows:

Area 1 White Room - A room used for the preparation of device subassemblies. Some radioactive Material is known to have been in this room and therefor it was designated as a primary survey area.

Area 2 — Pu-238 Device Assembly Area (Submarine Room) - The Pu-238 sealed sources were loaded into the thermo electric devices inside a containment structure known as the "submarine" located in the room. The containment was maintained under negative pressure by a ventilation system having HEPA filters in line prior to the roof discharge vents. Access and contamination controls were in place during these operations.

Area 3 — Facility Security Vault - The vault located in the administrative area contains a triply contained vessel containing approximately 740 grams of thoria. The container was opened and the integrity of the internal packaging was verified. The area was surveyed solely due to the presence of this material currently in the vault.

Area 4 — Pu-238 Source Storage Area - This area was controlled under heavy security during operations and contained all Pu-238 sealed sources not yet assembled into devices. The area is currently in use as a high security storage area and also contains the 1 mCi Radium source used for instrument calibration.

Area 5 — Pu-238 Source Testing and Measurement Area - This area is basically a floor space designated for the use of testing and measurement of the Assembled devices. The devices were lifted from a pedestal by and overhead crane where they were tested and measured while suspended above the floor.

Area 6 — Strontium Device Testing Area - This area is a sunken truck bay with a roll-up door access to the east end of the facility. The assembled Strontium devices were placed in the truck bay, tested and then repackaged for shipment all in the same area. No strontium containing devices were ever disassembled at the facility.

Area 7 — Source Storage Locker - This area is a locked file cabinet containing various check sources for use with the facility radiation detection instrumentation.

If the results of the preliminary detailed surveys in the seven designated R.A.M. areas and the conservative survey of the remainder of the former source security area did not indicate the presence of residual radioactive material, there would be little probability that the rest of the facility would have been adversely affected by the licensed operations. The survey plan for the rest of the facility would only be cursory in nature with several direct measurements and smears being assessed by field counting in each room or general activity area. The measurements taken in these areas would be focused on high traffic areas where it is likely that contamination, if spread to other sections of the facility, would be present in detectable quantities (see section on survey techniques).

The general plan for those areas designated as RAM locations include an initial gamma background rate measurement followed by local instrument background determinations for the other survey instruments. A detector window integrity test for the zinc sulfide α instrument would the be performed by holding the detector up to a source of fluorescent light. An increase in the background rate would indicate a loss of window integrity and the use of the instrument.

Randomly selected locations on horizontal and vertical surfaces in the rooms with areas of 100 cm^2 would then be measured directly with field instrumentation. At each location where the initial direct measurement is in excess of the background level, the measurement will be recorded. A swipe of each area would then be made to assess the levels of loose contamination on the surface. These swipes would be set aside for a period of 4 hours to allow for the decay of naturally occurring radionuclides (e.g. Radon progeny). After the decay period each swipe would be measured for alpha and beta contamination in a location that is not expected to have been affected by facility operations. A direct measurement of the surface would be made after the swipe was obtained to assess the level of fixed contamination at the location. If the results of any of the surveys presented evidence of unanticipated contamination above the surface contamination release guidelines (NRC Reg. Guide 1.86 criteria) at any of the measured locations, this would be an indication that further assessment would be required to allow a statistical characterization of the areas containing detectable activity. Swipes of the areas would be counted in either a proportional counter (set up for the detection of alpha particle emissions after a minimum decay period of 24 hours) or a liquid scintillation counter set up for the measurement of Pu-238 α emissions. Some portion of the population of swipes taken would be assessed by the proportional counter and some taken near the same locations will be assessed by liquid scintillation counting as a qualitative cross check of instrument reliability. Whereas the sensitivity of the hand held α detector is greater than that of either of the two laboratory instruments, the measurement of large area swipes (not a suitable media for assessment in the lab counters) using this field instrument was considered to be an acceptable alternative to exhaustive swipe collection and analysis if no measurable α activity could be found by direct measurements. Even in the case that no detectable activity would be discovered by field instrumentation on large area swipes, a suitable number of swipes will be analyzed by the laboratory instrumentation to document the status of the targeted R.A.M. areas.

If any of the "RAM" areas were found to be contaminated, a full survey would be performed to characterize the area and any affected adjacent areas until the full extent of the contamination could be determined. If no detectable contamination was found in the "RAM" areas the survey of the adjacent room will focus on common traffic patterns for personnel carrying radioactive material.

Following the surveys instrument operability checks will be repeated to demonstrate operability at the end of the survey.

3.2 Contingencies and Extended Survey Work

The nature and extent of any additional survey work required (characterization) would only be apparent when the results of the preliminary survey are known.

If long-lived alpha contamination was detected at the facility, provisions for the assessment of samples by alpha spectroscopy could be made to positively identify the contaminant as Plutonium-238.

Extended survey work necessary for the characterization of the contamination in the facility would be performed along the guidelines provided by the Nuclear Regulatory Commission. This type of survey was recommended (NUREG/CR 2082 1981) to document that a facility can be released to perform operations not involving the use of radioactive material and would require a much more extensive framework of area mapping and characterization. This extensive type of survey is meant to be used to document the effectiveness of a decontamination effort when it is known that a facility was at one time contaminated. The focus of the preliminary survey is to demonstrate that the facility has never been contaminated with the material it was licensed to handle.

Areas above any suspended ceilings and inside ventilation duct work would need to be assessed should any unanticipated contamination be found. Access to these areas and other normally inaccessible areas of the facility would be required in this unlikely circumstance.

4.0 SURVEY RESULTS AND SPECIALIZED SURVEY TECHNIQUES

The extensive direct radiation measurements made at the facility with field instrumentation and analysis of the numerous swipe samples by sensitive laboratory instrumentation confirm that no licensed radioactive materials are detectable above the ambient background level. This being the case, the facility has met the free release criteria as described in NRC Regulatory Guide 1.86, Table I by a wide margin of safety and is therefore suitable for occupation by another leaseholder.

Standard radiological survey techniques were employed to avoid cross contamination of swipe samples and to make direct measurements of surface activity (< 0.5" from surface without contact). Initially, small area tack cloth swipes (300 cm^2) of the targeted R.A.M. were taken and measured for both α and $ß/\gamma$ with the field instrumentation to assess the status of an area. These small area swipes would be appropriate in the event an area was found to be contaminated requiring detailed characterization of the distribution of activity on room surfaces. When no detectable radioactive material was found by direct measurements or on the small area tack cloth swipes, large area swipes (> 500 cm^2) were taken of the areas. In all cases these large area swipes were also found to be free of any detectable radioactive material.

The process of collection and analysis of large numbers of swipes (for area characterization) on media suitable for analysis by proportional counter and by liquid scintillation counting in this situation seemed pointless. A suitable number of these type of swipes were then taken in each area to verify the findings of the field instrument assessments and to provide a representative number of measurements of each area to allow an assessment of the radiological conditions in the unlikely event that the field instrument readings were faulty. All of these swipe samples were also measured for detectable α and β/γ activity prior to being sent to the laboratory for analysis. None of these swipe samples contained any activity detectable with the field instrumentation.

Other survey techniques employed for this survey involved measurements of locations in the facility where radioactive materials if present would have been concentrated. Specifically, drain traps, subfloor piping recesses, surfaces above suspended ceilings, room air exhaust duct work and associated air filtration support members were surveyed. In addition, work station vacuum cleaners, grime accumulations on old fan blade shields, and fume hood exhaust plenums were measured as areas where if loose surface contamination by licensed radioactive material had been present at any time it would be unlikely that these areas would have been affected by subsequent decontamination efforts. No evidence of residual licensed radioactive material was found in any of these locations

The majority of the floor surface of the former source security area including the workshop, shipping and receiving areas, tool cribs and material storage areas was unsealed concrete. Tack cloth was used to acquire large area swipes on these surfaces. No detectable activity either α or β/γ were detected on any of these swipes. On this type of surface, loose surface activity, if present, would have accumulated in corners and in cracks and crevices in the flooring. Extraction of some of this material from crevices and direct measurement of this material with field instruments would reveal the presence of historical facility contamination if it had been present. No evidence of licensed radioactive material was found in the crud residue excavated from these recesses or on any of the direct measurements made along these crevices.

The horizontal and vertical surfaces of all laboratories where radioactive material was present during facility operations were assessed by direct measurements and by swipe samples for the presence of residual activity. Where new surfaces had been applied since the cessation of radiological operations , the original surfaces were sought out and assessed. No evidence of residual licensed radioactive material was found in any of these measurements.

In the administrative areas of the facility, measurements of large area tack cloth swipes taken along major foot traffic patterns and in the relatively inaccessible areas below the stairwells did not indicate the presence of any residual contamination. Direct measurements of the areas along the bases of the walls and in corners where routine cleaning efforts were noticeably ineffective were also found to be free of residual

radioactive material. In areas where carpeting was installed, direct measurements of high traffic areas indicated by carpet wear, accumulations of sticky grime embedded into carpet fibers, and lower door closure recesses were assessed with no positive indications found.

None of the direct measurements of gamma background made with the pressurized ion chamber in any part of the facility (administrative or security areas) were in excess of 25 μR/hr with most of the measurements falling within the 10 to 20 μR/hr range.

The attached survey maps detail the survey work done in the six primary designated R.A.M. areas. On the maps of areas 1 and 2, the locations where the small area tack cloth wipes were taken are not indicated as they would unnecessarily clutter the diagram and interfere with the documentation of the locations where the proportional and liquid scintillation counter swipes were taken. No small area tack cloth swipes were taken in area 5 where large area swipes were used for the initial assessment. No map is attached for area 7 due to the small area involved. No fixed or loose surface activity was detected on any of the surfaces adjacent to this area (current source storage locker).

Joe Moon
J. Stewart Bland Associates, Inc.
133 Defense Highway, Suite 208
Annapolis, MD 21401

Dear Mr. Moon,

Thank you for choosing RSO, Inc. to provide you with radioanalytical services. The results for the 110 samples you recently delivered to our laboratory are summarized below.

The 100 paper wipes were analyzed using a Beckman LS6000 Liquid Scintillation Counter (LSC). The counter was properly calibrated and standardized to identify the alpha emissions of Pu-238. The minimum detectable activity for this analysis was 50 disintegrations per minute (DPM). None of the 100 wipes exceeded 50 DPM.

The 10 adhesive backed wipes were analyzed using a Baird-Atomic Gas Flow Proportional Counter (GFPC). This analysis is not isotope specific, the measurement is for gross alpha activity only. The MDA for this instrument was 2.8 DPM. None of the 10 wipes exceeded 2.8 DPM.

If you have any questions about this report or our analysis protocol, please call me. Thank you again for choosing RSO, Inc.

19-01398-34 030-04533
Inspection No. 76-01

Gentlemen:

This refers to the inspection conducted by Mr. J. Kinneman of this office on April 7, 1976 of activities authorized by NRC License Nos. SNM-849 and 19-01398-34 and to the discussions of our findings held by Mr. Kinneman with Messrs. McGrew and Tilmes of your staff at the conclusion of the inspection.

The inspection of License No. SNM-849 was limited to an examination of your material transfer records concerning the disposition of material authorized by the license, and to an examination of the contamination surveys of your facility and equipment. The inspection of License No. 19-01398-34 was limited to a discussion of the activities authorized by the license and to a review of your future plans. Within this scope, the inspection consisted of selective examiantions of survey records, interviews with personnel, observations by the inspector, and independent measurements made by the inspector.

Within the scope of this inspection, no items of noncompliance were observed.

In accordance with Section 2.790 of the NRC's "Rules of Practice", Part 2, Title 10, Code of Federal Regulations, a copy of this letter will be placed in the Public Document Room.

No reply to this letter is required; however, should you have any questions concerning this inspection, we will be pleased to discuss them with you.

Sincerely,

Paul R. Nelson

Attention: Mr. Donald A. Nussbaumer, Chief
Source and Special Nuclear Materials Branch

Subject: Cancellation of License No. SNM-849, Docket 70-908

Gentlemen:

The requirement for Teledyne Isotopes' Timonium, Maryland facility to retain a Special Nuclear Materials license has been critically evaluated. As a result of this evaluation, the decision has been made to terminate our SNM-849 license. Currently, three amendments to the license cover four items and these items will be discussed individually so that the rationale behind our conclusion can be presented.

1. Amendment 05, dated October 19, 1970, Items 6C, 7C and 8C covering 100 micrograms of elemental plutonium counter standards. Four counter standards are involved. The total activity is 6.5×10^{-8} Ci, considerably less than a licenseable quantity. The counter standards were never required to be on the license.

2. Amendment 05, dated October 19, 1970, Items 6E, 7E and 8E covering 100 grams of contained U-235, any enrichment, any form. The initial purpose was Research and Development as defined in 10 CFR 70.4 (j) and a later purpose was to demonstrate the capability of a thermal ionization source mass spectrometer which we manufacture for domestic and international sale. Currently, it is planned to do the calibration and demonstration of this device at the purchaser's facility because the RF noise in our own facility precludes that activity. We currently have no U-235 in house for this purppse. Regarding the R&D activity with U-235, none is currently underway and none is contemplated.

3. Amendment 10, dated June 6, 1974, Items 6F, 7F and 8F covering 100 micrograms of plutonium, any form. The purpose was to calibrate and demonstrate the mass spectrometer discussed in the previous paragraph. This activity cannot be accomplished because of the reason presented previously. We currently have no plutonium in house for this purpose.

3541

4. Amendment 12, dated November 1, 1974, Items 6G, 7G and 8G covering 300 grams total plutonium enriched in the isotope Pu-238 in seven sealed sources. This program is now concluded and we currently have no sealed source in house.

A comprehensive radiation survey has been made at the Teledyne Isotopes facility at 110 West Timonium Road, Timonium, Maryland. The survey consisted of a general portable instrument monitor supplemented by an extensive wipe test survey.

Instrumentation for the survey included:

Eberline E500B	Geiger Counter
Eberline PAC-1SA	Alpha Scintillation Meter
Eberline SAC-2	Scintillation Alpha Counter
NMC PCC-10A	Internal Proportional Counter

All areas that had been subjected to the use of radioactive materials were initially checked for contamination with the portable instruments, i.e., the E500B and PAC-1SA. All results of this survey were negative - no contamination was detected by the use of portable instruments.

The wipe test technique utilized for this survey consisted of smearing a dry filter paper over an area of approximately 100 cm^2 and counting the wipe in both the SAC-2 and the PCC-10A for alpha and beta/gamma activity, respectively. The SAC-2 operates with 35% efficiency and a background of $\sim$ 4 counts/minute. The PCC-10A operates with 50% efficiency and a background of $\sim$62 counts/minute. Efficiency and background readings were taken on both counters prior to counting the wipes and after the wipe counting had been concluded.

A total of 67 wipes were taken at various locations throughout the entire facility, concentrating on those areas where radioactive materials had been present. Results of this survey indicated minimal removable surface contamination. The maximum net results were less than 10 d/m/100 cm^2 for both alpha and beta/gamma activity from any one wipe. The details of this comprehensive survey are recorded in our permanent Health Physics Log.

The cancellation of our SNM-849 license is, of course, contingent upon approval of our survey results by the Division of Fuel Cycle and Material Safety and the Office of Inspection and Enforcement. Please let me know if further information is required.

Sincerely,

TELEDYNE ENERGY SYSTEMS

BWI Airport, Maryland 21240

SUBJECT: NRC REGION I INSPECTION NO. 94-001

Dear Ms. Brooks:

As Stephen Holmes of my staff discussed with you by telephone on October 20, 1994, the Nuclear Regulatory Commission (NRC) has been reviewing records to ensure that facilities, where activities were authorized by Atomic Energy Commission (AEC) and NRC licenses that have been terminated, are suitable for release for unrestricted use in accordance with current NRC guidelines. As you may be aware, the NRC and its predecessor, the AEC, issue licenses that authorize the use of various radioactive materials.

A contractor for the NRC, Oak Ridge National Laboratory (ORNL), initially reviewed each terminated license file and scored it according to a system designed to identify facilities that require additional review by the NRC staff. In general, files that indicate that radioactive material may have been used at particular facilities, but which do not include adequate final survey records for those facilities, are identified for additional review. The review by ORNL identified License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192 and STB-187 as files describing sites that require additional review. These licenses were issued to Martin-Marietta, Isotopes, Inc., and Ebasco and authorized activities at the Martin-Marietta Middle River Facility and the Martin State Airport. The Region I staff reviewed these files and determined that additional action was necessary since the information in the files did not provide sufficient detail to conclude that Buildings C, D, KJ and KC meet current guidelines for release for unrestricted use.

OFFICIAL RECORD COPY

RETURN ORIGINAL TO
REGION I

IE 07

On November 3, 1994, Mr. Holmes and Mr. Ray Manley of the Maryland Department of the Environment conducted an inspection at the Martin-Marietta Middle River Facility and Martin State Airport to determine whether radioactive contamination remains at those facilities as a result of activities previously authorized by these licensees. The findings of this inspection were discussed with a member of Mr. Jake West's staff, Glen Peregoy, at the conclusion of the inspection. The inspection report is enclosed with this letter.

As described in the enclosed report, the inspectors conducted a survey of each of the facilities and contacted and interviewed current and former employees of the licensees noted above. No radiation levels above background were identified at any of the sites. Only one building (C), in which only sealed sources were used, is presently being utilized. Another building (D) had been demolished and now only a concrete pad remains. The two remaining buildings (KJ and KC), on the Martin State Airport, have been abandoned and are scheduled for demolition pending remediation of asbestos and funding. Based on these facts and the findings described in the enclosed report, we plan no further action on these sites. They are suitable for unrestricted use.

In accordance with Section 2.790 of the NRC's "Rules of Practice," Part 2, Title 10, Code of Federal Regulations, a copy of this letter and the enclosed report will be placed in the Public Document Room. We will also provide copies to representatives of the State of Maryland.

No reply to this letter is required. Your cooperation with us is appreciated. If you have any questions, please contact Stephen Holmes at (610) 337-5390 or me at (610) 337-5252.

Sincerely,

Inspection Conducted: November 3, 1994

Inspector: Stephen W. Holmes, Radiation Specialist — 01/23/95 date

Approved by: John D. Kinneman, Chief
Site Decommissioning Section — 1/23/95 date

Inspection Summary: Closeout Verification Inspection No. 94-001.

Areas Inspected: Announced, inspection and survey of Buildings C and D at the Martin-Marietta Middle River facility and Buildings KJ and KC at the Martin State Airport.

Results: No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from the present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

Glen Peregoy, Engineer, Martin State Airport
* Jeffrey G. Smith, Manager Environmental Affairs, Martin Marietta
Jake West, Manager, Martin State Airport

* denotes those present at exit interview

2.0 Background

2.1 General

As part of a program to ensure that facilities where activities authorized by AEC and NRC licenses that have been terminated were suitable for release for unrestricted use as specified in current NRC criteria, the docket files for License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, and STB-187 were reviewed. Based on information in the files, the radiological status of four buildings could not be determined with certainty. These are Buildings C, D, on the Martin Marietta Corporation Middle River Facility and KJ (critical facility), and KC (radioisotope laboratory) on the Martin State Airport. Therefore, an onsite inspection was conducted. Prior to the on-site inspection, available records pertaining to the licensing, operation, and decommissioning of the activities in and around these buildings were reviewed by the inspector. Additionally, the inspector contacted two persons who had direct contact with these sites during actual operations or decommissioning: Mr. Thomas A. Flynn, Jr. the Project Manager of the 1965 "dismantling" of the Liquid Fluidized Bed Reactor (LFBR) at Building KC and Mr. Richard Brisson, a former employee of both Martin-Marietta, and Isotopes, Inc. Information obtained from these sources is documented in pertinent sections of this report.

2.2 Building D

Building D was located at the Martin-Marietta's Middle River, Maryland facility which is also called Chesapeake Park. Under License Nos. 19-01398-32, SNM-11, SNM-53, SNM-1192 and STB-187 a wide range of byproduct, source and special nuclear material were used in connection with various research and development activities in addition to work under government contracts. The facility was decontaminated in late 1970 under License No. SNM-1192, the license terminated, and the building subsequently demolished, leaving only the concrete basement floor/pad. An NRC inquiry regarding the site in June 1982 concluded that the site met the then current criteria for unrestricted use (Report Nos. 040-

03296/82-01 and 040-02308/82-011). However, there was no indication that a verification of the licensee's commitment to seal five contaminated drains with concrete was made.

2.3 Building C

Building C, also located at the Middle River site, was to have been used under License No. SNM-849 for operations involving encapsulated Pu-238 in conjunction with SNAP reactors and testing of fuel capsules and radioisotope generators containing Pu-238. This was reported to have occurred in the Environmental Test and Large Vacuum Chamber Laboratories. The building, which was being used as a warehouse at the time of this inspection, is a very large hanger type structure with a corresponding large basement. No records were available regarding the location of the laboratories within the building nor were any records of a termination or confirmatory survey of the facility available. Mr. Brisson stated that, to the best of his knowledge, only environmental and physical testing of the fueled SNAP and other radioisotope generators was performed in Building C and that no unsealed radioisotopes were used there. Additionally, he stated that the laboratories were located in the basement at the south west corner of the building and occupied an area no larger than 100' x 150' or 5 support pillars by 6 support pillars.

2.4 Building KJ

License No. 19-01398-20 was issued to Martin-Marietta for processing of Am-241 and Cm-242 in Building KJ which was designated the Radioisotope Laboratory and is located on the Martin State Airport property referred to as Strawberry Point, on a dirt access road off Strawberry Point Road, 330' S.W. of Building KC. This type of work had been previously performed in Building "D". The license was transferred to Isotopes, Inc. without a change in license number or location of work. In late 1969, Isotopes, Inc. requested termination of the license, simply stating that all radioactive material possessed under the license had been disposed of in accordance with 10 CFR 20 by transfer to a company authorized to receive the licensed material. The AEC terminated the license without comment. No record of a termination or confirmatory survey is in the docket file. Mr. Brisson stated that production processing did not occur in Building KJ and that only small source (μCi amounts of Am-241, no Cm-242) developmental operations to verify the chemistry were performed in the building. He and one other member of the Isotopes, Inc. staff performed the final cleanup and survey of the facility, including the removal and disposal of the HEPA filters. According to his memory, the survey demonstrating that the facility was ready for unconditional release was sent to the AEC contracting office on Hudson St., N.Y., N.Y.

2.5 Building KC

Building KC, the Critical Test Facility, was located 330' North East of Building KJ. The Martin-Marietta LFBR was situated in one of the building's three "test cells". Under License No. SNM-53 completed MH-1A fuel assemblies were stored in the test cells. License No. SNM-907 was issued to Ebasco Services, Inc. in 1965 for dismantling and removing the LFBR. The license included a provision to provide records of a post removal survey to the AEC's New York Operations Office and to Martin Marietta. Although a pre-dismantling survey was performed, no records of the required post removal survey could be found in the docket file. However, it was noted in the file that the LFBR never achieved criticality. Mr. Flynn stated that meticulous care was taken during the dismantling to prevent the spread of any contamination. Further, he stated that an AEC Inspector/Health Physicist from the New York Field Office/Laboratory was on site, oversaw the final survey, and signed the final report that asserted the dismantling of the LFBR had not added to or increased the contamination from the levels measured before the operation. Mr. Brisson confirmed that Ebasco's work produced no contamination throughout the rest of the building. Mr. Brisson also stated that his group decontaminated the underground LFBR water dump/holding tank by sandblasting the insides and disposing of the residue at a licensed burial site.

3.0 Instruments Used in Survey

During the survey three instruments were used, an Eberline PRM-6 with a 1" scintillator probe and a Ludlum Micro R meter Model 19 were used by the state inspector while a Ludlum Micro R meter Model 12 was used by the NRC inspector. The meters were calibrated, functional, and would detect gamma emitters of low energy and with good sensitivity. Based on the isotopes in question, these instrument were appropriate for this survey.

4.0 Survey Results

4.1 General

On November 3, 1994 surveys of each building/site were performed jointly by the NRC and State of Maryland inspectors. The inspectors surveyed each facility thoroughly and kept each other informed as to the results. The surveys were performed with the Micro R meters held at 0.5 meters above the surface with a forward movement of about 1.0 meters per second. In addition to Mr. Smith, who accompanied the inspectors to each site, Mr. Peregoy was present during the surveys of Buildings KC and KJ on the Martin State Airport property.

4.2 Building D

The Building D site was being use to store trailers under contract with the Army. The site consisted of a large concrete pad, the leftover basement floor of the old building. The pad had numerous cracks, holes, and was very weathered after two decades of exposure to the elements.

The inspectors surveyed the concrete pad along parallel lines 5 meters apart, paying attention to drains, clean-outs, and holes in the pad. In addition to measurements taken at drains and clean-outs, surface contact readings were also taken at approximately 10 meter intervals. Numerous sealed/filled in drains/clean-outs/penetrations/holes in the pad were located. Although a few places were found where a hole in the pad had been filled with concrete, it could not be determined if these were any of the drains referred to in the closeout survey. Martin Marietta staff stated that the rubble from the demolition of the building was the responsibility of the contractor and was removed and believed to have been disposed of in a landfill. No detectable radiation levels above background (5μR/hr) were found. No development or other use of the site is planned by Martin Marietta.

4.3 Building C

The Building C area where the old Environmental Test and Large Vacuum Chamber Laboratories were located is now warehouse space and a large empty room. With the exception of the support columns, no original walls, floors, ceiling, or ducts are left. The inspectors surveyed the area along parallel lines at 5 meter intervals with surface contact measurements every 5 meters and at drains and original concrete support columns. No radiation levels above background (5μR/hr) were detected.

4.4 Building KC

Building KC is at the end of a dirt access road off Strawberry Point road just east of the eastern most taxi way. The property was purchased in toto by the State of Maryland in 1975 and although the building was used in the past for storage, it has been abandoned and left open to the elements for the past ten to fifteen years. The site was completely abandoned, overgrown, exposed to the elements (of the three "test cells" only the one where the LFBR had been housed still had it's outer doors). The inspectors performed a walk-through survey of all three cells, the entrance way and connecting halls. Surface contact measurements were performed randomly throughout the building. The office/control room area was not entered due to the cluttered condition of and the layer of asbestos ceiling tiles covering the floor. No radiation levels above background were detected. Although an attempt was made to locate the underground dump/hold-up tank described by Mr. Brisson, the inspectors were unable to locate the tank or any indication that it had been removed. Based on discussion with Martin-Marietta and Martin State Airport personnel, it is believed that the tank was abandoned in place after the decontamination described in Section 2.5. The planning representative of Maryland Aviation stated that the building had been scheduled for demolition after remediation of the asbestos, but the plans were delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

4.5 Building KJ

Building KJ is 300' S.W. of building KC along the dirt access road. The

site was also completely abandoned, overgrown, exposed to the elements. The doors into the laboratory and, mechanical equipment room and office were ajar leaving the interior open to the outside. The inside was littered with "junk", leaves, bird and animal droppings, and dirt. A fair number of 100 lb. bags of "solidified" lime were present, as the building had been use for storage by the State of Maryland in the past. Rusted laboratory furniture and discarded fire extinguishers also littered the floor. The stainless steel ventilation duct-work and the laboratory hoods were still present less the duct-work section that had contained the HEPA filters. The inspectors surveyed the remains as well as possible given the state of the building. No radiation levels above background were detected. The planning representative of Maryland Aviation stated that the building, just like Building KC, had been scheduled for demolition after remediation of the asbestos, but the demolition was delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

5.0 Conclusions

No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

6.0 Exit Interview

The inspector met with the Martin-Marietta and Maryland Department of the Environment representatives listed in Section 1.0 of this report and discussed the scope and findings of this inspection. They acknowledged the inspection findings and the statements documented in this report. Messrs. Flynn and Brisson were contacted by telephone and also confirmed their statements in this report.

SUBJECT: NRC REGION I INSPECTION NO. 94-001

Dear Mr. Alcarese:

As Stephen Holmes of my staff discussed with you by telephone on October 20, 1994, the Nuclear Regulatory Commission (NRC) has been reviewing records to ensure that facilities, where activities were authorized by Atomic Energy Commission (AEC) and NRC licenses that have been terminated, are suitable for release for unrestricted use in accordance with current NRC guidelines. As you may be aware, the NRC and its predecessor, the AEC, issue licenses that authorize the use of various radioactive materials.

A contractor for the NRC, Oak Ridge National Laboratory (ORNL), initially reviewed each terminated license file and scored it according to a system designed to identify facilities that require additional review by the NRC staff. In general, files that indicate that radioactive material may have been used at particular facilities, but which do not include adequate final survey records for those facilities, are identified for our additional review. The review by ORNL identified License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192 and STB-187 as files describing sites that require additional review. These licenses were issued to Martin-Marietta, Isotopes, Inc. and Ebasco and authorized activities at the Martin-Marietta Middle River Facility and the Martin State Airport. The Region I staff reviewed these files and determined that additional action was necessary since the information in the files did not provide sufficient detail to conclude that Buildings C, D, KJ and KC meet current guidelines for release for unrestricted use.

On November 3, 1994, Mr. Holmes and Mr. Ray Manley of the Maryland Department of the Environment conducted an inspection at the Martin-Marietta Middle River Facility and Martin State Airport to determine whether radioactive contamination remains at the facility as a result of activities previously authorized by these licensees to Martin-Marietta, Isotopes, Inc., and Ebasco.

The inspection report is enclosed with this letter. The findings of this inspection were discussed with your representative, Mr. Jeffrey Smith, at the conclusion of the inspection.

As described in the enclosed report, the inspectors conducted a survey of each of the facilities and contacted and interviewed current and former employees of the licensees note above. No radiation levels above background were identified at any of the sites. Only one building (C), in which only sealed sources were used, is presently being utilized. Another building (D) had been demolished and now only a concrete pad remains. The two remaining buildings (KJ and KC), on the Martin State Airport, have been abandoned and scheduled for demolition pending remediation of asbestos and funding. Based on these facts and the findings annotated in the enclosed report, we plan no further actions on these sites. They are suitable for unrestricted use.

In accordance with Section 2.790 of the NRC's "Rules of Practice," Part 2, Title 10, Code of Federal Regulations, a copy of this letter and the enclosed report will be placed in the Public Document Room. We will also provide copies to representatives of the State of Maryland.

No reply to this letter is required. Your cooperation with us is appreciated. If you have any questions, please contact Stephen Holmes at (610) 337-5390 or me at (610) 337-5252.

Sincerely,

Report No. 94-001

Docket Nos. None, None, 070-00014, 070-00058, 070-00908, 070-00932, 070-00058, 040-03296

License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, STB-00187

Licensee: Martin-Marietta Aero & Naval Systems
103 Chesapeake Park Plaza
Baltimore, MD 21220

Facility Name: Middle River Facility and Martin State Airport

Inspection at: 2323 Eastern Blvd
Baltimore, MD
and
701 Wilson Point Road
Baltimore, MD

Inspection Conducted: November 3, 1994

Inspector: Stephen W. Holmes, Radiation Specialist — 01/23/95 date

Approved by: John D. Kinneman, Chief
Site Decommissioning Section — 1/23/95 date

Inspection Summary: Closeout Verification Inspection No. 94-001.

Areas Inspected: Announced, inspection and survey of Buildings C and D at the Martin-Marietta Middle River facility and Buildings KJ and KC at the Martin State Airport.

Results: No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from the present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

DETAILS

1.0 Persons Contacted

Joseph Alcarese, Esq.
Joanne Brooks, Environmental Specialist, Environmental Program Manager, Maryland Aviation Administration
Richard Brisson, former Acting Program Administrator, Maryland Dept. of the Environment, Radiological Health Program and former Martin-Marietta/Isotopes,Inc. employee
Thomas Flynn, Jr., Engineer, Raytheon (formally Ebasco Services, Inc.)
* Ray Manley, Inspector, Maryland Department of the Environment
Glen Peregoy, Engineer, Martin State Airport
* Jeffrey G. Smith, Manager Environmental Affairs, Martin Marietta
Jake West, Manager, Martin State Airport

* denotes those present at exit interview

2.0 Background

2.1 General

As part of a program to ensure that facilities where activities authorized by AEC and NRC licenses that have been terminated were suitable for release for unrestricted use as specified in current NRC criteria, the docket files for License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, and STB-187 were reviewed. Based on information in the files, the radiological status of four buildings could not be determined with certainty. These are Buildings C, D, on the Martin Marietta Corporation Middle River Facility and KJ (critical facility), and KC (radioisotope laboratory) on the Martin State Airport. Therefore, an onsite inspection was conducted. Prior to the on-site inspection, available records pertaining to the licensing, operation, and decommissioning of the activities in and around these buildings were reviewed by the inspector. Additionally, the inspector contacted two persons who had direct contact with these sites during actual operations or decommissioning: Mr. Thomas A. Flynn, Jr. the Project Manager of the 1965 "dismantling" of the Liquid Fluidized Bed Reactor (LFBR) at Building KC and Mr. Richard Brisson, a former employee of both Martin-Marietta, and Isotopes, Inc. Information obtained from these sources is documented in pertinent sections of this report.

2.2 Building D

Building D was located at the Martin-Marietta's Middle River, Maryland facility which is also called Chesapeake Park. Under License Nos. 19-01398-32, SNM-11, SNM-53, SNM-1192 and STB-187 a wide range of byproduct, source and special nuclear material were used in connection with various research and development activities in addition to work under government contracts. The facility was decontaminated in late 1970 under License No. SNM-1192, the license terminated, and the building subsequently demolished, leaving only the concrete basement floor/pad. An NRC inquiry regarding the site in June 1982 concluded that the site met the then current criteria for unrestricted use (Report Nos. 040-

03296/82-01 and 040-02308/82-011). However, there was no indication that a verification of the licensee's commitment to seal five contaminated drains with concrete was made.

2.3 Building C

Building C, also located at the Middle River site, was to have been used under License No. SNM-849 for operations involving encapsulated Pu-238 in conjunction with SNAP reactors and testing of fuel capsules and radioisotope generators containing Pu-238. This was reported to have occurred in the Environmental Test and Large Vacuum Chamber Laboratories. The building, which was being used as a warehouse at the time of this inspection, is a very large hanger type structure with a corresponding large basement. No records were available regarding the location of the laboratories within the building nor were any records of a termination or confirmatory survey of the facility available. Mr. Brisson stated that, to the best of his knowledge, only environmental and physical testing of the fueled SNAP and other radioisotope generators was performed in Building C and that no unsealed radioisotopes were used there. Additionally, he stated that the laboratories were located in the basement at the south west corner of the building and occupied an area no larger than 100' x 150' or 5 support pillars by 6 support pillars.

2.4 Building KJ

License No. 19-01398-20 was issued to Martin-Marietta for processing of Am-241 and Cm-242 in Building KJ which was designated the Radioisotope Laboratory and is located on the Martin State Airport property referred to as Strawberry Point, on a dirt access road off Strawberry Point Road, 330' S.W. of Building KC. This type of work had been previously performed in Building "D". The license was transferred to Isotopes, Inc. without a change in license number or location of work. In late 1969, Isotopes, Inc. requested termination of the license, simply stating that all radioactive material possessed under the license had been disposed of in accordance with 10 CFR 20 by transfer to a company authorized to receive the licensed material. The AEC terminated the license without comment. No record of a termination or confirmatory survey is in the docket file. Mr. Brisson stated that production processing did not occur in Building KJ and that only small source (μCi amounts of Am-241, no Cm-242) developmental operations to verify the chemistry were performed in the building. He and one other member of the Isotopes, Inc. staff performed the final cleanup and survey of the facility, including the removal and disposal of the HEPA filters. According to his memory, the survey demonstrating that the facility was ready for unconditional release was sent to the AEC contracting office on Hudson St., N.Y., N.Y.

2.5 Building KC

Building KC, the Critical Test Facility, was located 330' North East of Building KJ. The Martin-Marietta LFBR was situated in one of the building's three "test cells". Under License No. SNM-53 completed MH-1A fuel assemblies were stored in the test cells. License No. SNM-907 was issued to Ebasco Services, Inc. in 1965 for dismantling and removing the LFBR. The license included a provision to provide records of a post removal survey to the AEC's New York Operations Office and to Martin Marietta. Although a pre-dismantling survey was performed, no records of the required post removal survey could be found in the docket file. However, it was noted in the file that the LFBR never achieved criticality. Mr. Flynn stated that meticulous care was taken during the dismantling to prevent the spread of any contamination. Further, he stated that an AEC Inspector/Health Physicist from the New York Field Office/Laboratory was on site, oversaw the final survey, and signed the final report that asserted the dismantling of the LFBR had not added to or increased the contamination from the levels measured before the operation. Mr. Brisson confirmed that Ebasco's work produced no contamination throughout the rest of the building. Mr. Brisson also stated that his group decontaminated the underground LFBR water dump/holding tank by sandblasting the insides and disposing of the residue at a licensed burial site.

3.0 Instruments Used in Survey

During the survey three instruments were used, an Eberline PRM-6 with a 1" scintillator probe and a Ludlum Micro R meter Model 19 were used by the state inspector while a Ludlum Micro R meter Model 12 was used by the NRC inspector. The meters were calibrated, functional, and would detect gamma emitters of low energy and with good sensitivity. Based on the isotopes in question, these instrument were appropriate for this survey.

4.0 Survey Results

4.1 General

On November 3, 1994 surveys of each building/site were performed jointly by the NRC and State of Maryland inspectors. The inspectors surveyed each facility thoroughly and kept each other informed as to the results. The surveys were performed with the Micro R meters held at 0.5 meters above the surface with a forward movement of about 1.0 meters per second. In addition to Mr. Smith, who accompanied the inspectors to each site, Mr. Peregoy was present during the surveys of Buildings KC and KJ on the Martin State Airport property.

4.2 Building D

The Building D site was being use to store trailers under contract with the Army. The site consisted of a large concrete pad, the leftover basement floor of the old building. The pad had numerous cracks, holes, and was very weathered after two decades of exposure to the elements.

The inspectors surveyed the concrete pad along parallel lines 5 meters apart, paying attention to drains, clean-outs, and holes in the pad. In addition to measurements taken at drains and clean-outs, surface contact readings were also taken at approximately 10 meter intervals. Numerous sealed/filled in drains/clean-outs/penetrations/holes in the pad were located. Although a few places were found where a hole in the pad had been filled with concrete, it could not be determined if these were any of the drains referred to in the closeout survey. Martin Marietta staff stated that the rubble from the demolition of the building was the responsibility of the contractor and was removed and believed to have been disposed of in a landfill. No detectable radiation levels above background (5μR/hr) were found. No development or other use of the site is planned by Martin Marietta.

4.3 Building C

The Building C area where the old Environmental Test and Large Vacuum Chamber Laboratories were located is now warehouse space and a large empty room. With the exception of the support columns, no original walls, floors, ceiling, or ducts are left. The inspectors surveyed the area along parallel lines at 5 meter intervals with surface contact measurements every 5 meters and at drains and original concrete support columns. No radiation levels above background (5μR/hr) were detected.

4.4 Building KC

Building KC is at the end of a dirt access road off Strawberry Point road just east of the eastern most taxi way. The property was purchased in toto by the State of Maryland in 1975 and although the building was used in the past for storage, it has been abandoned and left open to the elements for the past ten to fifteen years. The site was completely abandoned, overgrown, exposed to the elements (of the three "test cells" only the one where the LFBR had been housed still had it's outer doors). The inspectors performed a walk-through survey of all three cells, the entrance way and connecting halls. Surface contact measurements were performed randomly throughout the building. The office/control room area was not entered due to the cluttered condition of and the layer of asbestos ceiling tiles covering the floor. No radiation levels above background were detected. Although an attempt was made to locate the underground dump/hold-up tank described by Mr. Brisson, the inspectors were unable to locate the tank or any indication that it had been removed. Based on discussion with Martin-Marietta and Martin State Airport personnel, it is believed that the tank was abandoned in place after the decontamination described in Section 2.5. The planning representative of Maryland Aviation stated that the building had been scheduled for demolition after remediation of the asbestos, but the plans were delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

4.5 Building KJ

Building KJ is 300' S.W. of building KC along the dirt access road. The

site was also completely abandoned, overgrown, exposed to the elements. The doors into the laboratory and, mechanical equipment room and office were ajar leaving the interior open to the outside. The inside was littered with "junk", leaves, bird and animal droppings, and dirt. A fair number of 100 lb. bags of "solidified" lime were present, as the building had been use for storage by the State of Maryland in the past. Rusted laboratory furniture and discarded fire extinguishers also littered the floor. The stainless steel ventilation duct-work and the laboratory hoods were still present less the duct-work section that had contained the HEPA filters. The inspectors surveyed the remains as well as possible given the state of the building. No radiation levels above background were detected. The planning representative of Maryland Aviation stated that the building, just like Building KC, had been scheduled for demolition after remediation of the asbestos, but the demolition was delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

5.0 Conclusions

No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

6.0 Exit Interview

The inspector met with the Martin-Marietta and Maryland Department of the Environment representatives listed in Section 1.0 of this report and discussed the scope and findings of this inspection. They acknowledged the inspection findings and the statements documented in this report. Messrs. Flynn and Brisson were contacted by telephone and also confirmed their statements in this report.

John D. Kinneman, Chief, Materials
Program Section No. 1 — 8/2/82 date

Inquiry Summary:

This inquiry consisted of telephone discussions and review of records provided by Martin-Marietta Corporation and NMSS to determine whether the facility at Middle River, Maryland formerly used for development and production of thorium-magnesium alloys meets current criteria for unrestricted use.

Results: The Middle River (Chesapeake Park) facility meets current criteria for release for unrestricted use.

Baltimore, Maryland 21201 (301-383-2744)

2. Background

Martin-Marietta Corporation, Baltimore Division, was authorized by License Nos. C-3991 and STB-187 during the late 1950's and early 1960's for the development and production of magnesium-thorium alloys and for possession and use of small quantities of uranium and thorium metal in connection with work under government contracts. License No. STB-187 expired on April 30, 1964. The authorized place of use was at Martin-Marietta's Middle River, Maryland facilities which are also called Chesapeake Park.

3. Telephone Discussions with Individuals

Individual A in paragraph 1 was formerly employed as the Health Physics Supervisor at Martin-Marietta and monitored the activities conducted under License Nos. C-3991 and STB-187. He stated that all work authorized by these licenses occurred in the basement of Building D at Chesapeake Park, Middle River, Maryland. Individual D also stated that a former Martin-Marietta employee had told him that Building D had been torn down and the site covered with grass after the building and the site were decontaminated.

Individual C searched Martin-Marietta records and found a close-out survey covering Building D and correspondence discussing the release of this facility for unrestricted use. He provided the correspondence and survey report in a letter dated June 1, 1982 (see Enclosure A) and confirmed that Building D had been torn down and the area where it stood is now covered with grass.

4. Review of Records

A letter from Martin-Marietta to the AEC dated September 21, 1970 (See Enclosure A) states that AEC License No. SNM-1192 was issued to Martin--Marietta Corporation to allow decontamination of their laboratory facilities and that a report of the decontamination was enclosed. The "Comprehensive Radiation Survey Report for the Release of Decontaminated Premises for Unrestricted Use," enclosed, provided the following points of comparison to the licenses and Individual A's statement:

a. The decontamination effort involved Building D at Chesapeake Park. Individual A stated that all work under License Nos. C-3991 and STB-187 occurred in this building.

b. Special nuclear material processes took place in Building D nuclear laboratories. The decontamination program consisted primarily of removal of U-235 and U-238 residual oxide forms. License No. C-3991 authorized use of uranium metal under government contracts while License No. STB-187 authorized the use of thorium.

Review of the close-out survey indicates that an extensive effort was made to remove all contamination according to AEC criteria and to protect the workers performing the decontamination. Contamination was removed from surfaces by use of high vacuum systems. Fixed contamination found on equipment such as hoods, ducts, glove boxes was allowed to remain fixed and the equipment was removed, properly packaged and shipped to Moorehead Kentucky for burial. Swipe tests were made and various kinds of radiation detectors were used during the decontamination. The report states that removable activities and radiation levels met AEC criteria for release for unrestricted use; however, no site diagram, showing where the swipes and measurements were taken, nor actual results of the measurements are provided.

The report states the average fixed alpha emitter contamination was less than 2000 dpm/100 cm^2, with no beta-gamma contamination, except for a small area of fixed Sr-90 contamination reading 0.5 mrad/hr. Except for the Sr-90 contamination, these results are within present NRC criteria of 5000 dpm/100cm^2 (average U-nat, U-235, U-238 and associated decay products) surface contamination. A fixed contamination level of 0.5 mrad/hr from Sr-90 does not meet the present NRC criteria; however, it is within the 2 mrem/hr limit for an unrestricted area in 10 CFR 20.105(b), and, since it was only a small spot, presented no hazard to personnel.

All water samples taken were stated to be less than or equal to 9.0×10^{-7} microcuries per ml compared to 10^{-5} microcuries per ml allowed for U-235 and U-238 in 10 CFR 20, Appendix B, Table II, Column 2. All soil samples were less than 10 pCi per gram U-238 or U-235 except for one sample having 24 pCi per gram of U-238. These results are consistent with the recent Uranium Fuel Licensing Branch position on disposal of uranium.

Residual activity in drains consisted of a total of 29 microcuries of U-235, which the licensee proposed to seal in place with cement.

5. Conclusion

Materials authorized by License Nos. C-3991 and STB-187 were used in Building D at Martin-Marietta's Middle River facilities which are also called Chesapeake Park. The Building D which was decontaminated and released for unrestricted use when AEC License SNM-1192 was terminated is the same facility where work authorized by License Nos. C-3991 and STB-187 was conducted. If any material remained from operations under these licenses it would have been detected and removed during that effort. No determination could be made if the drains containing residual U-235 activity were sealed with cement, however, since the building is now demolished and the site covered with grass this activity is unlikely to present a hazard.

Region I concludes the site meets current NRC criteria for release for unrestricted use and that no site survey is necessary.

Dear Mr. Nussbaumer:

Please be advised that the decontamination program at the Martin Marietta Corporation Baltimore facilities is nearing completion and it is anticipated the program shall be completed tentatively on August 5, 1970.

We request that an inspection of the subject facility be conducted on August 6, 1970, by a representative of your office in conjunction with the writer and a health physicist from the Eberline Instrument Corporation. If the above date is not compatible with your assignee's schedule and if there are questions regarding the above request and/or program, please advise the writer.

I wish to express my corporation's thanks and appreciation for the excellent service provided by representatives of your office toward bringing this program to a successful completion.

Sincerely yours,

MARTIN MARIETTA CORPORATION

I. INTRODUCTION

Purpose: This radiation survey report is prepared as one of the conditions provided for in U.S.A.E.C. Material License No. SNM-1192 issued to the Martin Marietta Corporation for the decontamination of nuclear laboratories at Baltimore, Maryland.

Since the subject nuclear laboratories are no longer used for radioisotopes operations and/or special nuclear materials processes and have been decontaminated in accordance with U.S.A.E.C. guidelines, it is requested the above named facilities be released for unrestricted use.

On June 3, 1970, the decontamination program at the Martin Marietta Corporation, Baltimore Division, commenced and it was completed on September 2, 1970. The radioactive materials involved in the decontamination program consisted primarily of U^{235} and U^{238} in a residual oxide form.

The work was performed by a crew consisting of 8 trained operators from the Martin Marietta Corporation, two health physicists from Eberline Instrument Corporation, and one health physicist from Martin Marietta Corporation. The removal of the radioactive material from equipment and facilities was achieved primarily through the use of high vacuum systems, with the operators wearing U.S. Bureau of Mines air supplied respirators. Full protective clothing and footwear were provided the workers.

Air samples were collected throughout the general area during the decontamination program and were counted for gross alpha emitters. The results of all air samples collected were below the MPC, with the exception of 4 samples. One sample was collected in the Radioisotopes Laboratory while chipping SR^{90} from a concrete wall. The result was reported as 2.4×10^{-10} uCi/CC. The second sample was collected in the Spheroidizing Room while removing ventilation ducts. The results of the air samples are given in Appendix C-1.

It should be noted that air supply respirators were worn by the operators during the time the air dust concentrations were measured. Urine specimens were submitted by personnel assigned to the program prior to working in the contaminated areas, in order to provide a base line study. Nasal swipes of all men working in the contaminated areas were performed twice daily. The results of all nasal swipes were low to negligible and did show proper use of respiratory protective equipment.

Water samples were collected of all liquid effluent, analyzed prior to release, and records of all sample analysis and personnel dosimetry reports are maintained in the office of the Martin Marietta Corporation's health physicist.

II. LOCATION AND IDENTIFICATION OF FACILITIES

The subject nuclear laboratories that were decontaminated are located at Chesapeake Park and are owned by Martin Marietta Corporation at Baltimore, Maryland. The decontaminated laboratories encompass an area of approximately 40,000 FT^2, located in the basement area of building "D". The total area was subdivided into small separate rooms where various types of nuclear activity were performed. Most of the small rooms were of the laboratory-type, and equipment included ventilation hoods, glove boxes, filtration medias, laboratory benches and laboratory glassware. False ceilings were also a part of some laboratories, and each ceiling was surveyed and removed, where necessary.

For the most part, the radioactivity was confined to glove boxes, ventilation hoods, ducts and filtration medias contained in each laboratory. The radioactive materials removed were in the form of residual uranium oxides, with the exception of a minor amount of SR^{90} found on a wall.

Some of the laboratories contained sinks, floor drains and sumps used to control liquid effluent containing radioactive materials. The floor drains, traps and sumps were carefully monitored to determine the contamination level, if any, and the termination location of each drain line and sump line.

III. HEALTH PHYSICS TECHNICAL APPROACH

The removal of residual contamination was accomplished through the direction and guidance of three health physicists, two from Eberline Instrument Corporation and one from Martin Marietta Corporation. The work crew consisted of eight qualified workers trained in the radiological health aspect of nuclear decontamination.

The contamination, for the most part, was not found to be tightly bonded or sealed to the surfaces of the facilities and therefore most of it was removed by the use of high vacuum systems with absolute filters. One wall and several floor areas showed evidence of bonded alpha activity and, therefore, it became necessary to use pneumatic tools to remove the contamination and reduce radiation levels to acceptable levels. Contamination that was found to be fixed on equipment, such as ventilation hoods, ducts and glove boxes, was allowed to remain fixed, and the equipment was properly packaged, identified and shipped by truck carrier to burial grounds in Moorehead, Kentucky. The transportation and burial of all contaminated equipment was provided by the Nuclear Engineering Company, Moorehead, Kentucky.

IV. SCOPE OF SURVEY AND GENERAL PROCEDURES FOLLOWED

Radiation detection equipment used during the effort included several gas proportional alpha counters, one floor alpha monitor, RM-15 (soft gamma measurement), one beta plus gamma counter, TLD badges and film badge dosimetry.

Swipe samples by the use of whatman filter paper were collected from all surface areas where it was thought to be necessary. The filter paper samples were then counted for any gross alpha contamination. All loose radioactive material was removed from the facilities. Equipment that was heavily contaminated, such as glove boxes and ventilation hoods, were properly packaged and shipped by carrier truck for burial.

There were no areas detected whereby radioactive materials had been sealed by painting or by other means, and there was no attempt to seal any areas containing fixed radioactive materials.

The general procedure followed to accomplish the decontamination effort is entitled "The Health and Safety Procedure for the Decontamination of Building "D", Martin Marietta Corporation, Baltimore, Maryland." The procedure is presently on file in the office of the U.S.A.E.C. Division of Materials Licensing. The procedure provided the basic guidelines for performing the decontamination in a safe manner. "The Guidelines for Decontamination of Facilities and Equipment Prior to Release for Unrestricted Use" was closely adhered to by the Martin Marietta Corporation decontamination work crew.

V. FINDINGS OF THE DECONTAMINATION SURVEY

The floors, walls and ceilings of all laboratories where nuclear activity was conducted were monitored and recleaned. Some areas did not show evidence of contamination. Those areas where contamination was found were vacuumed and sprayed with a jet-x cleaning device to remove any material that could not be vacuumed. The use of water was controlled and kept to a minimum to prevent water contamination and pollution.

During the initial phase of the decontamination inspection survey, six items or areas were found which required correction (letter to E. M. Chenault from S. J. Waligora, Jr., dated September 3, 1970) and all, with the exception of the floor drains, were corrected.

All floor drains were monitored and decontaminated as much as possible. Water samples were taken from the five drains indicating residual activity and all results showed low concentrations. (See Appendix C-2) The residual activity remaining in the six drains was estimated through the use of a 2" x 2" NaI(TR) crystal in conjunction with a single channel analyzer. With the detection system calibrated for ^{235}U gamma rays, the following estimates were established:

Drain No.	^{235}U(uCi)
39	1.0
46	1.0
52	15.0
55	6.0
56	6.0
Total	29.0

Water samples taken from these drains showed very low concentrations. As a further check, water was flushed continuously through these five drains while a two liter water sample was taken from the sanitary sewer sump servicing that portion of the building. Samples were submitted for analysis and showed 0.003 pCi/ml (MPC 30.0 pCi/ml).

All drains have been left open for inspection. With approval from the U.S. Atomic Energy Commission, we propose to seal the five drains with cement, thereby permanently inactivating the total of 29 uCi of ^{235}U. This measure would appear to be a feasible alternative to tearing out the concrete floor in order to remove the drains and associated pipe.

As a result of the final survey, all other areas were reduced to within limits prescribed by the U.S. Atomic Energy Commission. All walls, ceilings, and floors had been washed thoroughly or removed. The average alpha emitter contamination (^{235}U and/or ^{238}U only) is much less than 500 dpm/100 cm^2. Areas with remaining fixed alpha emitter contamination average less than 2,000 dpm/100 cm^2. Beta-gamma contamination is essentially nonexistent; ^{90}Sr-Y contamination which had been present in the Radioisotopes Laboratory has been completely removed with the exception of one minute area with fixed contamination measuring 0.5 mRad/hr.

This area of Building "D" will soon be renovated by Chesapeake Park and any remaining fixed contamination will be further enclosed with replastering, retiling of floors, and repainting. Following the renovation, any fixed residual contamination should be so well fixed that there should be no evidence of even trace quantities during the remaining life of the structure.

VI. PACKAGING, TRANSPORTATION AND DISPOSAL OF CONTAMINATED EQUIPMENT

All contaminated equipment, such as glove boxes, ventilation hoods and duct work, were properly packaged and identified in accordance with the Department of Transportation rules and regulations and sent by truck carrier to Moorehead, Kentucky, for burial. A total of nineteen (19) truckloads of equipment were sent to the burial grounds, with each truckload encompassing approximately 1,920 cubic feet.

APPENDIX B - SUMMARY OF DECONTAMINATION OPERATIONS

The following is a chronological task summary of decontamination operations from June 1 through September 3, 1970, and represents approximately 2400 man hours of labor.

1. Organization of people, equipment, supplies, and facilities; establishment of procedures and policies.
2. Removal of exhaust ducts from furnace room.
3. Samples taken from areas with potential for tritium and for cobalt 60 contamination.
4. Machinery and equipment removed from furnace room.
5. Areas expected to be clean were monitored and any anomalies entered to the work plan.
6. Arrangements were made for special disposal of nonradioactive but hazardous wastes (acids, alkalis, solvents, nitrates, peroxides, etc.)
7. Removed parafin shielding from neutron generator area.
8. Removed equipment from laundry area.
9. Surveyed dehydrator rooms and segregated areas and equipment.
10. Cleaned nine rooms which required general decontamination, but which posed no problems due to presence of contaminated equipment, exhaust ducts, absolute filters, etc.
11. Laundry area cleaned including removal of construction blocks and floor tiles.
12. Cleaned powder room - highly contaminated.
13. Discovered "contamination" in heat plant boiler room which analyses showed to be naturally occurring thorium.
14. Fire (primarily smoke) as the result of torches used during duct removal on outside of building by a local contractor. This duct work was past the absolute filter bands and there was no attendant radiation hazard

15. General cleaning accomplished in five additional rooms.

16. Vault decontaminated and bird cages removed.

17. Chipped concrete walls contaminated with ^{90}Sr-Y in Radioisotopes Laboratory.

18. Ductwork removal and clean-up in two additional rooms.

19. Removed glove boxes and other contaminated equipment from Spheroidizing Room; proceeded with remainder of clean-up.

20. Removed installed casework in Inorganic Chemistry Laboratory.

21. Decontaminated restroom floors in supposedly clean area.

22. Cleaned contamination which resulted from clean-up of Spheroidization Room.

23. Inspected Oil Farm Building (remote to Building "D") and removed contaminated equipment that had been stored. Survey showed no further decontamination was necessary.

24. Proceeded with clean-up of Inorganic Chemistry Laboratory.

25. Removed ducts and proceeded with clean-up of Powder Metal Room.

26. Removed duct and proceeding with clean-up of three rooms.

27. Removed duct work and equipment in Ceramics Laboratory and Spheroidization Laboratory.

28. Steamed Pellet Room in preparation to clean-up in order to reduce airborne (resuspended) contamination. Proceeded with clean-up.

29. Powder Room was also steamed prior to clean-up.

30. Removed absolute filters associated with Pellet Room.

31. All drains monitored and cleaned. Five remain contaminated.

32. Removed vertical rolling mill (several tons) from Powder Room. Residual contamination forced removal of two walls, ceilings, and floor tiles.

33. Ceiling and floor tiles removed in Spheroidization Room.

34. Removed absolute filters associated with Vault Room.

35. Final blowers, filters and ducts removed at termination and ventilation exhaust equipment.

36. Removed absolute filters and remainder of equipment associated with the Radioisotopes Laboratory.

37. Proceeded throughout entire facility with final monitoring and removed any contaminated items including floor tile, miscellaneous fixtures. Washed down all remaining ceilings, walls, and floors several times. A detailed swipe survey was performed.

38. Sumps and chip tanks associated with Dehydrator, Laundry Room, and Cleaning Room were decontaminated.

39. Asphalt floor covering in Cleaning Room removed.

40. Final waste shipment (19th truckload) departed. Two additional barrels filled with remaining miscellany for future shipment.

APPENDIX C - SAMPLE ANALYSIS RESULTS

1. Environmental Air Samples

Location	Date	Concentration (uCi/ec)
Radioisotopes Laboratory	7/9/70	$92.3 \pm 0.6 \times 10^{-12}$
Radioisotopes Laboratory	7/9/70	$240.0 \pm 1.0 \times 10^{-12}$

U. S. Nuclear Regulatory Commission
Division of Materials Licensing
Washington, D. C. 20545

Attention: Mr. Donald A. Nussbaumer
Chief
Source and Special Nuclear Materials Branch

Subject: Amendment to Renew License No. SNM-849, Docket No. 70-908

References:
(1) Title 10 Code of Federal Regulations
Parts 70.21, 70.22, 70.34 and 70.41(a).
(2) Letter dated September 26, 1974, P. J. Vogelberger, Jr., to D. A. Nussbaumer, Subject: Pu-238 Sealed Sources.
(3) Letter dated April 30, 1974, P. J. Vogelberger, Jr., to D. A. Nussbaumer, Subject: Mass Spectrometer Demonstration.
(4) Letter dated April 5, 1974, P. J. Vogelberger, Jr., to D. A. Nussbaumer, Subject: Mass Spectrometer Demonstration.

Gentlemen:

Teledyne Isotopes, Inc., requests that License No. SNM-849 be amended to:

(a) Extend its expiration date to that specified in Section B below.

(b) Permit the possession and use of material described in Section D below for the purposes and under the conditions described therein at the company's location at 110 West Timonium Road, Timonium, Maryland 21093.

A. Applicant

Teledyne Isotopes, Inc., a Division of Teledyne, Inc., is incorporated in the state of California with its headquarters office at 1901 Avenue of the Stars, Los Angeles, California 90067. The principal officers, who are citizens of the United States, are as follows:

Jack H. Hamilton	President 3401 Shiloh Road Garland, Texas 75041

1894

George A. Roberts	Vice-President 1901 Avenue of the Stars Los Angeles, California 90067
Peter J. Vogelberger, Jr.	Vice-President 110 West Timonium Road Timonium, Maryland 21093
Donald F. Schutz	Vice-President 50 Van Buren Avenue Westwood, New Jersey 07675
Henry E. Singleton	Chairman of the Board 1901 Avenue of the Stars Los Angeles, California 90067

Teledyne Isotopes, Inc., is not owned, controlled or dominated by an alien, a foreign corporation or a foreign government.

Teledyne Isotopes, Inc., has the responsibility for the operation of facilities at Timonium, Maryland for the performance of programs utilizing special nuclear materials.

B. Term of License

To continue nuclear programs utilizing special nuclear materials, Teledyne Isotopes, Inc., requests an extension of SNM License No. 849 subject to the provisions outlined herein as well as those terms and conditions set forth in 10 CFR Part 70. We request that the license remain in effect until October 31, 1980.

C. Use of Special Nuclear Material

The scope of utilization of special nuclear materials at Teledyne Isotopes' Timonium, Maryland facilities will involve the assembly of small sealed sources into thermoelectric generators, limited R & D activities, the use of SNM isotopic standards as a means of demonstrating the analytical capability of mass spectrometers (a Teledyne Isotopes product line) and alpha and neutron instrument check.

D. License Limits

1.	Pu	Plutonium dioxide enriched to ~ 80% Pu-238 in sealed sources. Details are contained in Ref. (2).	300 grams maximum
2.	U-235	Any enrichment, any chemical form for R & D activities and mass spectrometer demonstration. Details are included in Refs. (3) and (4).	100 grams maximum

3.	Pu	Any isotope, any chemical form, to demonstrate mass spectrometer. Details are included in Refs. (3) and (4).	100 micrograms maximum
4.	Four (4) metallic plutonium alpha counting standards. Details of use are included in F.17.a.		< 100 micrograms

E. Technical Qualifications

In November 1956, the Martin Company was granted its first Special Nuclear Material License by the Atomic Energy Commission. The prime requirement at that time was for enriched uranium for the fabrication of fuel to be used in design and criticality studies for the medium power portable reactor concept. Since that time, the Martin Company developed its technical efficiencies and production capabilities as a supplier of the nuclear fuel components under license for the PRO Critical Facility-CNEN and Pathfinder reactors. As a contractor of the New York Operations Office of the Atomic Energy Commission, portable medium power reactors were delivered to the AEC for generation of electrical power at remote installations in Sundance, Wyoming (PM-1) and McMurdo Sound, Antarctica (PM-3A). During this development in the atomic energy field, the Martin Company also built and operated a critical assembly facility for use in obtaining nuclear physics data in connection with various nuclear core designs. Slab type, as well as liquid fluidized bed experiments, were conducted in this facility under specific class 104 Facilities Licenses issued in accordance with Title 10 Code of Federal Regulations Part 50. The Martin Company was also the proponent and primary supplier of devices utilizing special nuclear material as well as byproduct material for Systems for Nuclear Auxiliary Power (SNAP).

The fulfillment of the programs discussed above has necessitated the assembly of a competent and highly skilled technical staff. Included are engineering, physics, metallurgy, design, and production talents. On August 5, 1968, Isotopes, Inc., acquired the former Martin Marietta Corporation Nuclear Division. This transaction involved acquisition of Martin's nuclear technical staff. This staff remains with Teledyne Isotopes at the Timonium facility where they provide a broadly diversified technical capability.

F. Internal Procedural Control to Insure Compliance with License Conditions

1. General

Teledyne Isotopes has established a system of internal checks and balances to provide reasonable assurance of complete compliance with licensing requirements and applicable laws, rules and regulations. This system provides for internal review and inspection of all safety aspects involved in the handling of special nuclear material. The following general statements of the responsibilities of the functional groups associated with safety aspects in the utilization of special nuclear material are presented below.

Manager, Materials Engineering and Test (R & D)

(1) Supervises all R & D activities involving special nuclear materials to assure that individual users comply with all rules and regulations during utilization of the material.

(2) Serves as the Teledyne Isotopes contact with regulatory agencies in all matters pertaining to radioactive materials.

(3) Determines the need for and obtains all necessary governmental approvals required in the utilization of radioactive materials.

(4) Develops the criteria for and administers the accountability program for radioactive materials.

(5) Conducts periodic operational reviews to appraise user's compliance with latest regulations.

(6) Interprets and disseminates applicable regulatory information to activities concerned.

Supervisor, Health Physics

(1) Develops and administers the health physics program to minimize the hazard to personnel and reduce company liability during the utilization of radioactive materials.

(2) Monitors user performance to assure safety as well as compliance with rules and regulations.

(3) Reviews and approves each planned material usage.

Supervisor, Security

(1) Shall be responsible to establish security control areas and maintain surveillance of employee activities to assure compliance with Security requirements.

Criticality Engineer

(1) Shall be responsible for establishing safety criteria, as required, for operational procedures and monitoring operations to assure compliance with such criteria.

2. Technical, Personnel Qualifications

Manager, SNM R & D

Education:	B.S. in Chemistry, Chemical Engineering, or B.S. Physics or Engineering with graduate work in either chemistry or nuclear engineering.
Experience:	Minimum of 5 years experience in chemical system design, experimental system operation or related scientific type work.

Supervisor, Health Physics

Education:	B.S. in Physics, Chemistry, Math, Physical Sciences or equivalent.
Experience:	Four (4) years experience in Health Physics administration and control procedure with particular emphasis being placed on personnel possessing a broad spectrum of Health Physics experience as well as a knowledge of nuclear instrumentation or general electronics.

Criticality Engineer

Education:	B.S. in Physics, Engineering Physics or B.S. in Engineering, Chemistry with graduate work in physics or nuclear engineering.
Experience:	Minimum of 3 years experience in reactor physics design, nuclear experimental work and/or other related scientific type work.

G. Radiological Safety Controls and General Facility Requirements

Since Teledyne Isotopes forecasts no need for the handling and processing of large quantities of Uranium-235 and/or plutonium, criticality control will not be the limiting factor. The major emphasis will be placed upon radiological control to assure adequate personnel safeguards and compliance with applicable rules and regulations.

Uranium and plutonium compounds, in forms which can readily become airborne, will be handled only in contained atmospheres, or adequately ventilated enclosures in the case of uranium.

H. Special Nuclear Material Storage

All SNM accountable under this license will be stored in a Secure Fuel Storage Room or in a locked cabinet when not in use or awaiting shipment in an approved shipping container. Access to stored material will be controlled by Health Physics personnel and Security.

I. Radiological Safety Program

1. Introduction

The fundamental prerequisite for the operation of any nuclear facility is assurance that it will present no undue hazard to the health and safety of facility personnel or to the general public.

The basic radiological safety objectives for the achievement of this requirement are (1) to preclude the uncontrolled release of radioactivity to the normally occupied areas within the facility and/or to the outside environment, and (2) to limit the radiation exposure of facility personnel to the lowest practicable level and in compliance with established radiation protection standards.

The standards used in the conduct of the Teledyne Isotopes radiological safety program are in conformance with the recommendations and guides contained in the following publications: Title 10, Code of Federal Regulations; Federal Radiation Council; National Committee on Radiological Protection; National Bureau of Standards; and State Radiation Protection Codes.

2. Responsibility for the Radiological Safety Program

Responsibility for radiological safety, as for any other health and safety matter, rests with management and is discharged through management's representative.

Technical direction of the radiological safety program has been delegated to the Supervisor, Health Physics Section. This responsibility includes the development and maintenance of a complete and integrated program for radiation protection. The methods by which radiation safety is achieved involve the analysis of postulated hazards resulting from both routine and accidental occurrences within the facility and evaluation of the effectiveness of the control and surveillance mechanisms instituted to cope with any unique radiation problem which might arise.

3. Scope of the Radiological Safety Program

Teledyne Isotopes' Health Physics Section provides direct support in all programs concerned with radiation and radioactive materials. The major elements of this radiological safety program are:

(a) Nuclear facilities design consultation and approval.

(b) Program plan review.

(c) Radiological indoctrination and training.

(d) Personnel exposure surveillance and documentation including bioassay.

(e) Facilities, operations and environmental monitoring.

(f) Radioactive material hazard control.

(g) Radioactive waste disposal surveillance.

(h) Emergency planning and capability.

(i) Liaison with regulatory agencies.

4. Health Physics Experience

The individuals comprising the Health Physics Section have had wide experience in organizing and conducting Radiological Safety programs supporting the following nuclear activities:

(a) Research, power and production reactors and nuclear accelerators.

(b) Radiochemical processing plants, hot cell operations, and high level gamma and x-radiation facilities.

(c) Large scale environmental monitoring and waste disposal programs, radioactive material transportation problems, personnel monitoring and instrumentation development, evaluation and calibration.

5. Radiological Safety Organization

The Health Physics Section provides radiation protection services on a level-of-effort basis. The Supervisor, Health Physics Section, reports to the Manager, Materials Engineering and Test. In addition, he reports on a "dotted line" to the Vice-President of Teledyne Isotopes and also serves as the Radiation Protection Officer.

6. Radiation Surveys

Survey and control procedures are utilized to evaluate radiological hazards and establish effective control measures to limit personnel exposure. These surveys are conducted to determine radiation levels, the presence or absence of surface contamination and/or airborne radioactivity in work or occupancy areas. The surveys are usually performed by technicians under the supervision of a health physicist.

As a result of these surveys, suitable control measures are imposed to insure adequate personnel protection. The frequency and extent of the surveys are governed by the work performed or by existing conditions. Documentation of all surveys are recorded in operational logs.

7. External Dose Rate Measurements

The measurement of external dose rates is conducted using portable monitoring instruments. Selection of a particular instrument is based upon the type, energy and intensity of the radiation to be monitored. Portable monitoring instruments in use are calibrated at least once every three months and after each repair.

8. Surface Contamination Measurement

Each area where radioactive materials are utilized is surveyed for the presence of fixed and loose contamination. The frequency of these surveys is governed by the nature and type of operations performed. An accelerated survey schedule is employed during the initial phases of any new process or change in process to determine any unusual radiological hazard. Thereafter when work is in progress, a general daily survey is conducted in the work areas at locations which are most likely to indicate changes in contamination levels. If this general survey indicates an increase in contamination level, a detailed survey is initiated to determine the cause and institute measures to reduce or possibly eliminate the source of contamination.

Loose contamination is evaluated employing the wipe technique which consists of wiping an absorbent paper over an area of approximately 100 cm^2 and counting the wipe in a shielded detector-scaler assembly.

Alpha survey instruments are utilized to monitor floors and equipment for fixed alpha contamination.

Instrumentation used to evaluate contamination and radiation is listed in Table 1.

The contamination criteria currently in use is as follows:

Unrestricted Area	Removable	Max. Fixed	Avg. Fixed
All alpha contamination	100 dpm/100 cm^2	2500 dpm/100 cm^2	500 dpm/100 cm^2

9. Surface Contamination Control

Surface contamination is controlled in the fabrication area by employing one or a combination of the following techniques:

(a) Performing regular surveys to determine contamination levels.

(b) Providing ventilation at the sources of dispersable contaminants.

(c) Establishing isolated areas when dispersable contaminants are generated.

(d) Utilizing absorbent paper, polyethylene and coatings on equipment and exchanging these during the course of the work.

(e) Employing step off pads at entrances to isolated areas.

(f) Requiring the use of anti-contamination clothing.

The spread of dispersable contaminants to unrestricted areas is minimized by:

(a) Establishing buffer zones between the areas and providing frequent contamination surveys.

(b) Monitoring personnel at the point of egress from an isolated area.

(c) Monitoring equipment and utilizing an equipment check tag system.

(d) Providing receptacles for contaminated wastes and used anti-contamination clothing.

(e) Controlling the wearing of anti-contamination clothing outside of a restricted area.

10. Personnel Contamination Control

Anti-contamination clothing requirements are specified by Health Physics prior to starting any operation where potential contaminants may be encountered. These requirements are based upon operational experience and/or survey results.

Anti-contamination clothing will be laundered when required by an approved outside firm providing such service or disposed of as radioactive waste.

11. Description of Decontamination Techniques

Floor contamination is normally removed by scrubbing with mops and detergent solutions. Persistent contamination is removed by employing a mechanical scrubber and steel wool pads. The scrub solution is removed with a wet type vacuum cleaner and finally damp mopped. Waste solution is discharged to the sanitary sewer after sampling and evaluation has shown that the concentration is within the limits prescribed by 10 CFR 20.303.

Equipment contamination is removed by scrubbing with detergents and water or wiping with damp cloths. Large metal machinery and hand tools are decontaminated by wiping with solvent to minimize corrosion. Contaminated scrubbing equipment, mops and wipes are discarded as solid radioactive waste.

12. Airborne Radioactivity Measurement

Breathing zone air samples are collected on an accelerated schedule during the initial phases of any new process or change in process. The sample results are used to evaluate the particulate airborne radioactivity concentrations associated with the process and provide a basis for instituting special requirements to reduce the airborne contamination levels in accordance with the guides set forth in 10 CFR 20. After the initial breathing zone sample evaluations, general area samples are collected adjacent to any potential contamination producing operation.

Exhaust stack air samples are routinely collected and analyzed from the ventilation system exhaust whenever work is being conducted which could involve contamination dispersion of the environs. The samples are collected downstream from each exhaust system fan prior to exhausting to the environs. Air samples are collected using open face of in-line filter holders containing filter paper.

Air sample filters are counted and analyzed employing detector-scaler assemblies. The procedure can adequately determine concentrations prescribed by 10 CFR 20.103 and .106.

13. Personnel Exposure Surveillance

Personnel exposure surveillance is conducted to measure the amount of external and internal radiation exposure received by individuals whose work involves exposure to ionizing radiation.

14. Personnel Monitoring Methods

All personnel permanently assigned to work in areas where exposure to ionizing radiation is likely are required to wear film badges. Additional monitoring devices are issued as dictated by the type of work performed.

Thermoluminescent dosimeters (TLD badges) are used in all cases when personnel monitoring is required, whereas, neutron film is used only when personnel are exposed to neutron radiation. Film packets are processed and evaluated quarterly or after any suspect or unusual exposure as indicated by supplementary monitoring devices. Visitors are monitored in accordance with 10 CFR 20.202.

In those instances where handling of loose dispersable types of radioactive materials by specific personnel becomes necessary, those individuals are required to submit bioassay samples for analysis if there exists the possibility of a suspected body intake of radioactive material.

15. Records

Results of all personnel exposures are posted in the individual's exposure file where a cumulative exposure record is maintained.

16. Instrumentation and Related Equipment

A description of the radiation survey and related equipment utilized in the conduct of the radiological safety program is presented in Table 1.

17. Method, Frequency and Standards Used in Calibrating Instruments

a. Portable Radiation Detection Instruments

All portable survey meters in use are calibrated at least once every three months or after each servicing. A 1 mg Ra-226 source is used to calibrate beta-gamma instruments.

Neutron survey instruments are calibrated out of house. Calibration is generally performed out of doors to reduce scattering from building walls, etc. The instrument is adjusted to read the calculated neutron dose rate after adjusting the bias against gamma radiation.

Alpha survey meters are calibrated against reference sources of uranium and the metallic plutonium alpha counting standards listed in D.3 and adjusted to read the known value in counts per minute based upon the manufacturer's recommendations concerning counter efficiency.

b. Detector/Scaler Counting Assemblies

Background and statistical accuracy checks are made on all counting room instrumentation prior to use. Calibrated alpha and beta-gamma reference sources are placed in each detector and counted for a preset time. If the instrument readings vary greater than the calculated statistical error, it is recalibrated and the counter efficiency is then determined by comparing the counter count rate with that of the standard source.

c. Instrument Maintenance and Records

Minor instrument repairs and calibrations are performed by Health Physics personnel. Major repairs are performed by the facility instrument technician.

Health Physics maintains permanent records of all instrument calibrations and repair records are maintained by the instrument technician. Each instrument is tagged indicating the calibration date.

18. Radioactive Waste Disposal

All radioactive waste will be disposed in accordance with 10 CFR 20.301. A record for each container of waste, indicating the type of waste, approximate quantity, radiation and contamination level is maintained in the Health Physics office.

Please let me know if further information is required.

Sincerely,

TELEDYNE ISOTOPES, INC.

John W. McGrew
Licensing and Accountability Representative

NRC Reviewer:	David F. Limroth, Stephan W. Holmes		
Review Abstract:	License No. STB-00187 authorized the possession and use of large amounts of thorium alloy in Building D at Middle River, Maryland from 1961 to 1964. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces. The building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on November 3, 1994 indicate that the site is suitable for unrestricted use.		
Recommendations:	None.		

Summary: License No. STB-00187, which superseded C-04283 on January 1, 1961, authorized possession of up to 100,000 pounds of thorium-magnesium alloy (4 percent thorium) for fabrication of missile components. The license was terminated on March 20, 1964 at the request of the licensee. Region I Inspection Report No. 40-3296/82-01 documents that all work under License No. STB-00187 was conducted in Building D at the Middle River facility.

Information from various docket files indicates that a variety of activities with large amounts of byproduct, source, and special nuclear material were authorized at Building D at the Middle River facility. Activities with licensed material at Building D ceased prior to 1970. License No. SNM-1192 was issued to Martin-Marietta on May 22, 1970 and authorized the decontamination of the Martin-Marietta, Middle River, Maryland facility. License No. SNM-1192 has the same Docket No. (70-58) as License No. SNM-53 and all records for License No. SNM-1192 are contained in the docket file for License No. SNM-53. Apparently only Building D was decontaminated under License No. SNM-1192. Building D was decontaminated from June to September 1970 and a final survey report provided to the AEC with a letter dated September 22, 1970. The final survey report states that a total of 29 μCi of U-235 remained in five drains which were to be were sealed with concrete; one small area of fixed Sr-90 contamination (0.5 mrad/hr) also remained. The building was demolished after the survey,

January 23, 1995

A1287

leaving only the concrete pad. Region I staff reviewed the available documentation in 1982 and concluded in Combined Inspection Report Nos. 40-3296/82-01 and 40-2308/82-01 that the site met NRC criteria for unrestricted use.

An NRC site visit and survey was performed on November 3, 1994 to assure that the site meets current NRC guidelines for release for unrestricted use. Buildings C and D at the Middle River facility and Buildings KJ and KC at the Martin State Airport were surveyed. The results of the surveys indicate no radiation or contamination levels above background in any of the buildings surveyed, including the concrete pad remaining from Building D. The contaminated drains discussed in the final survey report regarding Building D were not located, although a number of openings in the pad which had been filled with concrete were identified. Therefore, it seems apparent that the drains identified as contaminated during the final survey were plugged with concrete, as proposed by the licensee. Based on the fact that no radiation or contamination levels above background were detected, it seems unlikely that U-235 contamination in the drains, if present, is a significant hazard. Therefore, the site is suitable for unrestricted use.

NRC Reviewer:	David F. Limroth, Stephen W. Holmes		

Review Abstract: License No. SNM-00011 authorized research and development work with U-235 in Building D at Middle River, Maryland. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces. The building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on November 3, 1994 indicate that the site is suitable for unrestricted use.

Recommendations: None.

Summary: License No. SNM-00011 authorized the possession and use of 2 kilograms of U-235 in enriched uranium for fuel element research and development to be used in the licensee's Nuclear Materials Laboratory in Building D, Plant I. The licensee's letter dated September 19, 1957 requested that certain special operations in the fabrication of fuel bundles be permitted in the pilot manufacturing facility and in other buildings at Plant I. The licensee specified that only fully clad uranium fuel tubes or plates would be used in these other buildings. The license expired on May 31, 1961 and was not renewed. On April 7, 1961, the licensee ceritifed that all material possessed under the license had been disposed of prior to expiration of the license.

Information from various docket files indicates that a variety of activities with large amounts of byproduct, source, and special nuclear material were authorized at Building D at the Middle River facility. Activities with licensed material at Building D ceased prior to 1970. License No. SNM-1192 was issued to Martin-Marietta on May 22, 1970 and authorized the decontamination of the Martin-Marietta, Middle River, Maryland facility. Inspection at: 2323 Eastern Blvd
Baltimore, MD
and
701 Wilson Point Road
Baltimore, MD

Inspection Conducted: November 3, 1994

Inspector: Stephen W. Holmes, Radiation Specialist — 01/23/95 date

Approved by: John D. Kinneman, Chief
Site Decommissioning Section — 1/23/95 date

Inspection Summary: Closeout Verification Inspection No. 94-001.

Areas Inspected: Announced, inspection and survey of Buildings C and D at the Martin-Marietta Middle River facility and Buildings KJ and KC at the Martin State Airport.

Results: No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from the present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

2.0 Background

2.1 General

As part of a program to ensure that facilities where activities authorized by AEC and NRC licenses that have been terminated were suitable for release for unrestricted use as specified in current NRC criteria, the docket files for License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, and STB-187 were reviewed. Based on information in the files, the radiological status of four buildings could not be determined with certainty. These are Buildings C, D, on the Martin Marietta Corporation Middle River Facility and KJ (critical facility), and KC (radioisotope laboratory) on the Martin State Airport. Therefore, an onsite inspection was conducted. Prior to the on-site inspection, available records pertaining to the licensing, operation, and decommissioning of the activities in and around these buildings were reviewed by the inspector. Additionally, the inspector contacted two persons who had direct contact with these sites during actual operations or decommissioning: Mr. Thomas A. Flynn, Jr. the Project Manager of the 1965 "dismantling" of the Liquid Fluidized Bed Reactor (LFBR) at Building KC and Mr. Richard Brisson, a former employee of both Martin-Marietta, and Isotopes, Inc. Information obtained from these sources is documented in pertinent sections of this report.

2.2 Building D

Building D was located at the Martin-Marietta's Middle River, Maryland facility which is also called Chesapeake Park. Under License Nos. 19-01398-32, SNM-11, SNM-53, SNM-1192 and STB-187 a wide range of byproduct, source and special nuclear material were used in connection with various research and development activities in addition to work under government contracts. The facility was decontaminated in late 1970 under License No. SNM-1192, the license terminated, and the building subsequently demolished, leaving only the concrete basement floor/pad. An NRC inquiry regarding the site in June 1982 concluded that the site met the then current criteria for unrestricted use (Report Nos. 040-

03296/82-01 and 040-02308/82-011). However, there was no indication that a verification of the licensee's commitment to seal five contaminated drains with concrete was made.

2.3 Building C

Building C, also located at the Middle River site, was to have been used under License No. SNM-849 for operations involving encapsulated Pu-238 in conjunction with SNAP reactors and testing of fuel capsules and radioisotope generators containing Pu-238. This was reported to have occurred in the Environmental Test and Large Vacuum Chamber Laboratories. The building, which was being used as a warehouse at the time of this inspection, is a very large hanger type structure with a corresponding large basement. No records were available regarding the location of the laboratories within the building nor were any records of a termination or confirmatory survey of the facility available. Mr. Brisson stated that, to the best of his knowledge, only environmental and physical testing of the fueled SNAP and other radioisotope generators was performed in Building C and that no unsealed radioisotopes were used there. Additionally, he stated that the laboratories were located in the basement at the south west corner of the building and occupied an area no larger than 100' x 150' or 5 support pillars by 6 support pillars.

2.4 Building KJ

License No. 19-01398-20 was issued to Martin-Marietta for processing of Am-241 and Cm-242 in Building KJ which was designated the Radioisotope Laboratory and is located on the Martin State Airport property referred to as Strawberry Point, on a dirt access road off Strawberry Point Road, 330' S.W. of Building KC. This type of work had been previously performed in Building "D". The license was transferred to Isotopes, Inc. without a change in license number or location of work. In late 1969, Isotopes, Inc. requested termination of the license, simply stating that all radioactive material possessed under the license had been disposed of in accordance with 10 CFR 20 by transfer to a company authorized to receive the licensed material. The AEC terminated the license without comment. No record of a termination or confirmatory survey is in the docket file. Mr. Brisson stated that production processing did not occur in Building KJ and that only small source (μCi amounts of Am-241, no Cm-242) developmental operations to verify the chemistry were performed in the building. He and one other member of the Isotopes, Inc. staff performed the final cleanup and survey of the facility, including the removal and disposal of the HEPA filters. According to his memory, the survey demonstrating that the facility was ready for unconditional release was sent to the AEC contracting office on Hudson St., N.Y., N.Y.

2.5 Building KC

Building KC, the Critical Test Facility, was located 330' North East of Building KJ. The Martin-Marietta LFBR was situated in one of the building's three "test cells". Under License No. SNM-53 completed MH-1A fuel assemblies were stored in the test cells. License No. SNM-907 was issued to Ebasco Services, Inc. in 1965 for dismantling and removing the LFBR. The license included a provision to provide records of a post removal survey to the AEC's New York Operations Office and to Martin Marietta. Although a pre-dismantling survey was performed, no records of the required post removal survey could be found in the docket file. However, it was noted in the file that the LFBR never achieved criticality. Mr. Flynn stated that meticulous care was taken during the dismantling to prevent the spread of any contamination. Further, he stated that an AEC Inspector/Health Physicist from the New York Field Office/Laboratory was on site, oversaw the final survey, and signed the final report that asserted the dismantling of the LFBR had not added to or increased the contamination from the levels measured before the operation. Mr. Brisson confirmed that Ebasco's work produced no contamination throughout the rest of the building. Mr. Brisson also stated that his group decontaminated the underground LFBR water dump/holding tank by sandblasting the insides and disposing of the residue at a licensed burial site.

3.0 Instruments Used in Survey

During the survey three instruments were used, an Eberline PRM-6 with a 1" scintillator probe and a Ludlum Micro R meter Model 19 were used by the state inspector while a Ludlum Micro R meter Model 12 was used by the NRC inspector. The meters were calibrated, functional, and would detect gamma emitters of low energy and with good sensitivity. Based on the isotopes in question, these instrument were appropriate for this survey.

4.0 Survey Results

4.1 General

On November 3, 1994 surveys of each building/site were performed jointly by the NRC and State of Maryland inspectors. The inspectors surveyed each facility thoroughly and kept each other informed as to the results. The surveys were performed with the Micro R meters held at 0.5 meters above the surface with a forward movement of about 1.0 meters per second. In addition to Mr. Smith, who accompanied the inspectors to each site, Mr. Peregoy was present during the surveys of Buildings KC and KJ on the Martin State Airport property.

4.2 Building D

The Building D site was being use to store trailers under contract with the Army. The site consisted of a large concrete pad, the leftover basement floor of the old building. The pad had numerous cracks, holes, and was very weathered after two decades of exposure to the elements.

The inspectors surveyed the concrete pad along parallel lines 5 meters apart, paying attention to drains, clean-outs, and holes in the pad. In addition to measurements taken at drains and clean-outs, surface contact readings were also taken at approximately 10 meter intervals. Numerous sealed/filled in drains/clean-outs/penetrations/holes in the pad were located. Although a few places were found where a hole in the pad had been filled with concrete, it could not be determined if these were any of the drains referred to in the closeout survey. Martin Marietta staff stated that the rubble from the demolition of the building was the responsibility of the contractor and was removed and believed to have been disposed of in a landfill. No detectable radiation levels above background (5μR/hr) were found. No development or other use of the site is planned by Martin Marietta.

4.3 Building C

The Building C area where the old Environmental Test and Large Vacuum Chamber Laboratories were located is now warehouse space and a large empty room. With the exception of the support columns, no original walls, floors, ceiling, or ducts are left. The inspectors surveyed the area along parallel lines at 5 meter intervals with surface contact measurements every 5 meters and at drains and original concrete support columns. No radiation levels above background (5μR/hr) were detected.

4.4 Building KC

Building KC is at the end of a dirt access road off Strawberry Point road just east of the eastern most taxi way. The property was purchased in toto by the State of Maryland in 1975 and although the building was used in the past for storage, it has been abandoned and left open to the elements for the past ten to fifteen years. The site was completely abandoned, overgrown, exposed to the elements (of the three "test cells" only the one where the LFBR had been housed still had it's outer doors). The inspectors performed a walk-through survey of all three cells, the entrance way and connecting halls. Surface contact measurements were performed randomly throughout the building. The office/control room area was not entered due to the cluttered condition of and the layer of asbestos ceiling tiles covering the floor. No radiation levels above background were detected. Although an attempt was made to locate the underground dump/hold-up tank described by Mr. Brisson, the inspectors were unable to locate the tank or any indication that it had been removed. Based on discussion with Martin-Marietta and Martin State Airport personnel, it is believed that the tank was abandoned in place after the decontamination described in Section 2.5. The planning representative of Maryland Aviation stated that the building had been scheduled for demolition after remediation of the asbestos, but the plans were delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

4.5 Building KJ

Building KJ is 300' S.W. of building KC along the dirt access road. The

site was also completely abandoned, overgrown, exposed to the elements. The doors into the laboratory and, mechanical equipment room and office were ajar leaving the interior open to the outside. The inside was littered with "junk", leaves, bird and animal droppings, and dirt. A fair number of 100 lb. bags of "solidified" lime were present, as the building had been use for storage by the State of Maryland in the past. Rusted laboratory furniture and discarded fire extinguishers also littered the floor. The stainless steel ventilation duct-work and the laboratory hoods were still present less the duct-work section that had contained the HEPA filters. The inspectors surveyed the remains as well as possible given the state of the building. No radiation levels above background were detected. The planning representative of Maryland Aviation stated that the building, just like Building KC, had been scheduled for demolition after remediation of the asbestos, but the demolition was delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

5.0 Conclusions

No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

6.0 Exit Interview

The inspector met with the Martin-Marietta and Maryland Department of the Environment representatives listed in Section 1.0 of this report and discussed the scope and findings of this inspection. They acknowledged the inspection findings and the statements documented in this report. Messrs. Flynn and Brisson were contacted by telephone and also confirmed their statements in this report.

BWI Airport, Maryland 21240

SUBJECT: NRC REGION I INSPECTION NO. 94-001

Dear Ms. Brooks:

As Stephen Holmes of my staff discussed with you by telephone on October 20, 1994, the Nuclear Regulatory Commission (NRC) has been reviewing records to ensure that facilities, where activities were authorized by Atomic Energy Commission (AEC) and NRC licenses that have been terminated, are suitable for release for unrestricted use in accordance with current NRC guidelines. As you may be aware, the NRC and its predecessor, the AEC, issue licenses that authorize the use of various radioactive materials.

A contractor for the NRC, Oak Ridge National Laboratory (ORNL), initially reviewed each terminated license file and scored it according to a system designed to identify facilities that require additional review by the NRC staff. In general, files that indicate that radioactive material may have been used at particular facilities, but which do not include adequate final survey records for those facilities, are identified for additional review. The review by ORNL identified License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192 and STB-187 as files describing sites that require additional review. These licenses were issued to Martin-Marietta, Isotopes, Inc., and Ebasco and authorized activities at the Martin-Marietta Middle River Facility and the Martin State Airport. The Region I staff reviewed these files and determined that additional action was necessary since the information in the files did not provide sufficient detail to conclude that Buildings C, D, KJ and KC meet current guidelines for release for unrestricted use.

RETURN ORIGINAL TO
REGION I

IE 07

A/29D

On November 3, 1994, Mr. Holmes and Mr. Ray Manley of the Maryland Department of the Environment conducted an inspection at the Martin-Marietta Middle River Facility and Martin State Airport to determine whether radioactive contamination remains at those facilities as a result of activities previously authorized by these licensees. The findings of this inspection were discussed with a member of Mr. Jake West's staff, Glen Peregoy, at the conclusion of the inspection. The inspection report is enclosed with this letter.

As described in the enclosed report, the inspectors conducted a survey of each of the facilities and contacted and interviewed current and former employees of the licensees noted above. No radiation levels above background were identified at any of the sites. Only one building (C), in which only sealed sources were used, is presently being utilized. Another building (D) had been demolished and now only a concrete pad remains. The two remaining buildings (KJ and KC), on the Martin State Airport, have been abandoned and are scheduled for demolition pending remediation of asbestos and funding. Based on these facts and the findings described in the enclosed report, we plan no further action on these sites. They are suitable for unrestricted use.

In accordance with Section 2.790 of the NRC's "Rules of Practice," Part 2, Title 10, Code of Federal Regulations, a copy of this letter and the enclosed report will be placed in the Public Document Room. We will also provide copies to representatives of the State of Maryland.

No reply to this letter is required. Your cooperation with us is appreciated. If you have any questions, please contact Stephen Holmes at (610) 337-5390 or me at (610) 337-5252.

Sincerely,

Inspector: Stephen W. Holmes, Radiation Specialist — 01/23/95 date

Approved by: John D. Kinneman, Chief
Site Decommissioning Section — 1/23/95 date

Inspection Summary: Closeout Verification Inspection No. 94-001.

Areas Inspected: Announced, inspection and survey of Buildings C and D at the Martin-Marietta Middle River facility and Buildings KJ and KC at the Martin State Airport.

Results: No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from the present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

Glen Peregoy, Engineer, Martin State Airport
* Jeffrey G. Smith, Manager Environmental Affairs, Martin Marietta
Jake West, Manager, Martin State Airport

* denotes those present at exit interview

2.0 Background

2.1 General

As part of a program to ensure that facilities where activities authorized by AEC and NRC licenses that have been terminated were suitable for release for unrestricted use as specified in current NRC criteria, the docket files for License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, and STB-187 were reviewed. Based on information in the files, the radiological status of four buildings could not be determined with certainty. These are Buildings C, D, on the Martin Marietta Corporation Middle River Facility and KJ (critical facility), and KC (radioisotope laboratory) on the Martin State Airport. Therefore, an onsite inspection was conducted. Prior to the on-site inspection, available records pertaining to the licensing, operation, and decommissioning of the activities in and around these buildings were reviewed by the inspector. Additionally, the inspector contacted two persons who had direct contact with these sites during actual operations or decommissioning: Mr. Thomas A. Flynn, Jr. the Project Manager of the 1965 "dismantling" of the Liquid Fluidized Bed Reactor (LFBR) at Building KC and Mr. Richard Brisson, a former employee of both Martin-Marietta, and Isotopes, Inc. Information obtained from these sources is documented in pertinent sections of this report.

2.2 Building D

Building D was located at the Martin-Marietta's Middle River, Maryland facility which is also called Chesapeake Park. Under License Nos. 19-01398-32, SNM-11, SNM-53, SNM-1192 and STB-187 a wide range of byproduct, source and special nuclear material were used in connection with various research and development activities in addition to work under government contracts. The facility was decontaminated in late 1970 under License No. SNM-1192, the license terminated, and the building subsequently demolished, leaving only the concrete basement floor/pad. An NRC inquiry regarding the site in June 1982 concluded that the site met the then current criteria for unrestricted use (Report Nos. 040-

03296/82-01 and 040-02308/82-011). However, there was no indication that a verification of the licensee's commitment to seal five contaminated drains with concrete was made.

2.3 Building C

Building C, also located at the Middle River site, was to have been used under License No. SNM-849 for operations involving encapsulated Pu-238 in conjunction with SNAP reactors and testing of fuel capsules and radioisotope generators containing Pu-238. This was reported to have occurred in the Environmental Test and Large Vacuum Chamber Laboratories. The building, which was being used as a warehouse at the time of this inspection, is a very large hanger type structure with a corresponding large basement. No records were available regarding the location of the laboratories within the building nor were any records of a termination or confirmatory survey of the facility available. Mr. Brisson stated that, to the best of his knowledge, only environmental and physical testing of the fueled SNAP and other radioisotope generators was performed in Building C and that no unsealed radioisotopes were used there. Additionally, he stated that the laboratories were located in the basement at the south west corner of the building and occupied an area no larger than 100' x 150' or 5 support pillars by 6 support pillars.

2.4 Building KJ

License No. 19-01398-20 was issued to Martin-Marietta for processing of Am-241 and Cm-242 in Building KJ which was designated the Radioisotope Laboratory and is located on the Martin State Airport property referred to as Strawberry Point, on a dirt access road off Strawberry Point Road, 330' S.W. of Building KC. This type of work had been previously performed in Building "D". The license was transferred to Isotopes, Inc. without a change in license number or location of work. In late 1969, Isotopes, Inc. requested termination of the license, simply stating that all radioactive material possessed under the license had been disposed of in accordance with 10 CFR 20 by transfer to a company authorized to receive the licensed material. The AEC terminated the license without comment. No record of a termination or confirmatory survey is in the docket file. Mr. Brisson stated that production processing did not occur in Building KJ and that only small source (μCi amounts of Am-241, no Cm-242) developmental operations to verify the chemistry were performed in the building. He and one other member of the Isotopes, Inc. staff performed the final cleanup and survey of the facility, including the removal and disposal of the HEPA filters. According to his memory, the survey demonstrating that the facility was ready for unconditional release was sent to the AEC contracting office on Hudson St., N.Y., N.Y.

2.5 Building KC

Building KC, the Critical Test Facility, was located 330' North East of Building KJ. The Martin-Marietta LFBR was situated in one of the building's three "test cells". Under License No. SNM-53 completed MH-1A fuel assemblies were stored in the test cells. License No. SNM-907 was issued to Ebasco Services, Inc. in 1965 for dismantling and removing the LFBR. The license included a provision to provide records of a post removal survey to the AEC's New York Operations Office and to Martin Marietta. Although a pre-dismantling survey was performed, no records of the required post removal survey could be found in the docket file. However, it was noted in the file that the LFBR never achieved criticality. Mr. Flynn stated that meticulous care was taken during the dismantling to prevent the spread of any contamination. Further, he stated that an AEC Inspector/Health Physicist from the New York Field Office/Laboratory was on site, oversaw the final survey, and signed the final report that asserted the dismantling of the LFBR had not added to or increased the contamination from the levels measured before the operation. Mr. Brisson confirmed that Ebasco's work produced no contamination throughout the rest of the building. Mr. Brisson also stated that his group decontaminated the underground LFBR water dump/holding tank by sandblasting the insides and disposing of the residue at a licensed burial site.

3.0 Instruments Used in Survey

During the survey three instruments were used, an Eberline PRM-6 with a 1" scintillator probe and a Ludlum Micro R meter Model 19 were used by the state inspector while a Ludlum Micro R meter Model 12 was used by the NRC inspector. The meters were calibrated, functional, and would detect gamma emitters of low energy and with good sensitivity. Based on the isotopes in question, these instrument were appropriate for this survey.

4.0 Survey Results

4.1 General

On November 3, 1994 surveys of each building/site were performed jointly by the NRC and State of Maryland inspectors. The inspectors surveyed each facility thoroughly and kept each other informed as to the results. The surveys were performed with the Micro R meters held at 0.5 meters above the surface with a forward movement of about 1.0 meters per second. In addition to Mr. Smith, who accompanied the inspectors to each site, Mr. Peregoy was present during the surveys of Buildings KC and KJ on the Martin State Airport property.

4.2 Building D

The Building D site was being use to store trailers under contract with the Army. The site consisted of a large concrete pad, the leftover basement floor of the old building. The pad had numerous cracks, holes, and was very weathered after two decades of exposure to the elements.

The inspectors surveyed the concrete pad along parallel lines 5 meters apart, paying attention to drains, clean-outs, and holes in the pad. In addition to measurements taken at drains and clean-outs, surface contact readings were also taken at approximately 10 meter intervals. Numerous sealed/filled in drains/clean-outs/penetrations/holes in the pad were located. Although a few places were found where a hole in the pad had been filled with concrete, it could not be determined if these were any of the drains referred to in the closeout survey. Martin Marietta staff stated that the rubble from the demolition of the building was the responsibility of the contractor and was removed and believed to have been disposed of in a landfill. No detectable radiation levels above background (5μR/hr) were found. No development or other use of the site is planned by Martin Marietta.

4.3 Building C

The Building C area where the old Environmental Test and Large Vacuum Chamber Laboratories were located is now warehouse space and a large empty room. With the exception of the support columns, no original walls, floors, ceiling, or ducts are left. The inspectors surveyed the area along parallel lines at 5 meter intervals with surface contact measurements every 5 meters and at drains and original concrete support columns. No radiation levels above background (5μR/hr) were detected.

4.4 Building KC

Building KC is at the end of a dirt access road off Strawberry Point road just east of the eastern most taxi way. The property was purchased in toto by the State of Maryland in 1975 and although the building was used in the past for storage, it has been abandoned and left open to the elements for the past ten to fifteen years. The site was completely abandoned, overgrown, exposed to the elements (of the three "test cells" only the one where the LFBR had been housed still had it's outer doors). The inspectors performed a walk-through survey of all three cells, the entrance way and connecting halls. Surface contact measurements were performed randomly throughout the building. The office/control room area was not entered due to the cluttered condition of and the layer of asbestos ceiling tiles covering the floor. No radiation levels above background were detected. Although an attempt was made to locate the underground dump/hold-up tank described by Mr. Brisson, the inspectors were unable to locate the tank or any indication that it had been removed. Based on discussion with Martin-Marietta and Martin State Airport personnel, it is believed that the tank was abandoned in place after the decontamination described in Section 2.5. The planning representative of Maryland Aviation stated that the building had been scheduled for demolition after remediation of the asbestos, but the plans were delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

4.5 Building KJ

Building KJ is 300' S.W. of building KC along the dirt access road. The

site was also completely abandoned, overgrown, exposed to the elements. The doors into the laboratory and, mechanical equipment room and office were ajar leaving the interior open to the outside. The inside was littered with "junk", leaves, bird and animal droppings, and dirt. A fair number of 100 lb. bags of "solidified" lime were present, as the building had been use for storage by the State of Maryland in the past. Rusted laboratory furniture and discarded fire extinguishers also littered the floor. The stainless steel ventilation duct-work and the laboratory hoods were still present less the duct-work section that had contained the HEPA filters. The inspectors surveyed the remains as well as possible given the state of the building. No radiation levels above background were detected. The planning representative of Maryland Aviation stated that the building, just like Building KC, had been scheduled for demolition after remediation of the asbestos, but the demolition was delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

5.0 Conclusions

No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

6.0 Exit Interview

The inspector met with the Martin-Marietta and Maryland Department of the Environment representatives listed in Section 1.0 of this report and discussed the scope and findings of this inspection. They acknowledged the inspection findings and the statements documented in this report. Messrs. Flynn and Brisson were contacted by telephone and also confirmed their statements in this report.

SUBJECT: NRC REGION I INSPECTION NO. 94-001

Dear Mr. Alcarese:

As Stephen Holmes of my staff discussed with you by telephone on October 20, 1994, the Nuclear Regulatory Commission (NRC) has been reviewing records to ensure that facilities, where activities were authorized by Atomic Energy Commission (AEC) and NRC licenses that have been terminated, are suitable for release for unrestricted use in accordance with current NRC guidelines. As you may be aware, the NRC and its predecessor, the AEC, issue licenses that authorize the use of various radioactive materials.

A contractor for the NRC, Oak Ridge National Laboratory (ORNL), initially reviewed each terminated license file and scored it according to a system designed to identify facilities that require additional review by the NRC staff. In general, files that indicate that radioactive material may have been used at particular facilities, but which do not include adequate final survey records for those facilities, are identified for our additional review. The review by ORNL identified License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192 and STB-187 as files describing sites that require additional review. These licenses were issued to Martin-Marietta, Isotopes, Inc. and Ebasco and authorized activities at the Martin-Marietta Middle River Facility and the Martin State Airport. The Region I staff reviewed these files and determined that additional action was necessary since the information in the files did not provide sufficient detail to conclude that Buildings C, D, KJ and KC meet current guidelines for release for unrestricted use.

On November 3, 1994, Mr. Holmes and Mr. Ray Manley of the Maryland Department of the Environment conducted an inspection at the Martin-Marietta Middle River Facility and Martin State Airport to determine whether radioactive contamination remains at the facility as a result of activities previously authorized by these licensees to Martin-Marietta, Isotopes, Inc., and Ebasco.

The inspection report is enclosed with this letter. The findings of this inspection were discussed with your representative, Mr. Jeffrey Smith, at the conclusion of the inspection.

As described in the enclosed report, the inspectors conducted a survey of each of the facilities and contacted and interviewed current and former employees of the licensees note above. No radiation levels above background were identified at any of the sites. Only one building (C), in which only sealed sources were used, is presently being utilized. Another building (D) had been demolished and now only a concrete pad remains. The two remaining buildings (KJ and KC), on the Martin State Airport, have been abandoned and scheduled for demolition pending remediation of asbestos and funding. Based on these facts and the findings annotated in the enclosed report, we plan no further actions on these sites. They are suitable for unrestricted use.

In accordance with Section 2.790 of the NRC's "Rules of Practice," Part 2, Title 10, Code of Federal Regulations, a copy of this letter and the enclosed report will be placed in the Public Document Room. We will also provide copies to representatives of the State of Maryland.

No reply to this letter is required. Your cooperation with us is appreciated. If you have any questions, please contact Stephen Holmes at (610) 337-5390 or me at (610) 337-5252.

Sincerely,

701 Wilson Point Road
Baltimore, MD

Inspection Conducted: November 3, 1994

Inspector: Stephen W. Holmes, Radiation Specialist — 01/23/95 date

Approved by: John D. Kinneman, Chief
Site Decommissioning Section — 1/23/95 date

Inspection Summary: Closeout Verification Inspection No. 94-001.

Areas Inspected: Announced, inspection and survey of Buildings C and D at the Martin-Marietta Middle River facility and Buildings KJ and KC at the Martin State Airport.

Results: No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from the present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

DETAILS

1.0 Persons Contacted

Joseph Alcarese, Esq.
Joanne Brooks, Environmental Specialist, Environmental Program Manager, Maryland Aviation Administration
Richard Brisson, former Acting Program Administrator, Maryland Dept. of the Environment, Radiological Health Program and former Martin-Marietta/Isotopes,Inc. employee
Thomas Flynn, Jr., Engineer, Raytheon (formally Ebasco Services, Inc.)
* Ray Manley, Inspector, Maryland Department of the Environment
Glen Peregoy, Engineer, Martin State Airport
* Jeffrey G. Smith, Manager Environmental Affairs, Martin Marietta
Jake West, Manager, Martin State Airport

* denotes those present at exit interview

2.0 Background

2.1 General

As part of a program to ensure that facilities where activities authorized by AEC and NRC licenses that have been terminated were suitable for release for unrestricted use as specified in current NRC criteria, the docket files for License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, and STB-187 were reviewed. Based on information in the files, the radiological status of four buildings could not be determined with certainty. These are Buildings C, D, on the Martin Marietta Corporation Middle River Facility and KJ (critical facility), and KC (radioisotope laboratory) on the Martin State Airport. Therefore, an onsite inspection was conducted. Prior to the on-site inspection, available records pertaining to the licensing, operation, and decommissioning of the activities in and around these buildings were reviewed by the inspector. Additionally, the inspector contacted two persons who had direct contact with these sites during actual operations or decommissioning: Mr. Thomas A. Flynn, Jr. the Project Manager of the 1965 "dismantling" of the Liquid Fluidized Bed Reactor (LFBR) at Building KC and Mr. Richard Brisson, a former employee of both Martin-Marietta, and Isotopes, Inc. Information obtained from these sources is documented in pertinent sections of this report.

2.2 Building D

Building D was located at the Martin-Marietta's Middle River, Maryland facility which is also called Chesapeake Park. Under License Nos. 19-01398-32, SNM-11, SNM-53, SNM-1192 and STB-187 a wide range of byproduct, source and special nuclear material were used in connection with various research and development activities in addition to work under government contracts. The facility was decontaminated in late 1970 under License No. SNM-1192, the license terminated, and the building subsequently demolished, leaving only the concrete basement floor/pad. An NRC inquiry regarding the site in June 1982 concluded that the site met the then current criteria for unrestricted use (Report Nos. 040-

03296/82-01 and 040-02308/82-011). However, there was no indication that a verification of the licensee's commitment to seal five contaminated drains with concrete was made.

2.3 Building C

Building C, also located at the Middle River site, was to have been used under License No. SNM-849 for operations involving encapsulated Pu-238 in conjunction with SNAP reactors and testing of fuel capsules and radioisotope generators containing Pu-238. This was reported to have occurred in the Environmental Test and Large Vacuum Chamber Laboratories. The building, which was being used as a warehouse at the time of this inspection, is a very large hanger type structure with a corresponding large basement. No records were available regarding the location of the laboratories within the building nor were any records of a termination or confirmatory survey of the facility available. Mr. Brisson stated that, to the best of his knowledge, only environmental and physical testing of the fueled SNAP and other radioisotope generators was performed in Building C and that no unsealed radioisotopes were used there. Additionally, he stated that the laboratories were located in the basement at the south west corner of the building and occupied an area no larger than 100' x 150' or 5 support pillars by 6 support pillars.

2.4 Building KJ

License No. 19-01398-20 was issued to Martin-Marietta for processing of Am-241 and Cm-242 in Building KJ which was designated the Radioisotope Laboratory and is located on the Martin State Airport property referred to as Strawberry Point, on a dirt access road off Strawberry Point Road, 330' S.W. of Building KC. This type of work had been previously performed in Building "D". The license was transferred to Isotopes, Inc. without a change in license number or location of work. In late 1969, Isotopes, Inc. requested termination of the license, simply stating that all radioactive material possessed under the license had been disposed of in accordance with 10 CFR 20 by transfer to a company authorized to receive the licensed material. The AEC terminated the license without comment. No record of a termination or confirmatory survey is in the docket file. Mr. Brisson stated that production processing did not occur in Building KJ and that only small source (μCi amounts of Am-241, no Cm-242) developmental operations to verify the chemistry were performed in the building. He and one other member of the Isotopes, Inc. staff performed the final cleanup and survey of the facility, including the removal and disposal of the HEPA filters. According to his memory, the survey demonstrating that the facility was ready for unconditional release was sent to the AEC contracting office on Hudson St., N.Y., N.Y.

2.5 Building KC

Building KC, the Critical Test Facility, was located 330' North East of Building KJ. The Martin-Marietta LFBR was situated in one of the building's three "test cells". Under License No. SNM-53 completed MH-1A fuel assemblies were stored in the test cells. License No. SNM-907 was issued to Ebasco Services, Inc. in 1965 for dismantling and removing the LFBR. The license included a provision to provide records of a post removal survey to the AEC's New York Operations Office and to Martin Marietta. Although a pre-dismantling survey was performed, no records of the required post removal survey could be found in the docket file. However, it was noted in the file that the LFBR never achieved criticality. Mr. Flynn stated that meticulous care was taken during the dismantling to prevent the spread of any contamination. Further, he stated that an AEC Inspector/Health Physicist from the New York Field Office/Laboratory was on site, oversaw the final survey, and signed the final report that asserted the dismantling of the LFBR had not added to or increased the contamination from the levels measured before the operation. Mr. Brisson confirmed that Ebasco's work produced no contamination throughout the rest of the building. Mr. Brisson also stated that his group decontaminated the underground LFBR water dump/holding tank by sandblasting the insides and disposing of the residue at a licensed burial site.

3.0 Instruments Used in Survey

During the survey three instruments were used, an Eberline PRM-6 with a 1" scintillator probe and a Ludlum Micro R meter Model 19 were used by the state inspector while a Ludlum Micro R meter Model 12 was used by the NRC inspector. The meters were calibrated, functional, and would detect gamma emitters of low energy and with good sensitivity. Based on the isotopes in question, these instrument were appropriate for this survey.

4.0 Survey Results

4.1 General

On November 3, 1994 surveys of each building/site were performed jointly by the NRC and State of Maryland inspectors. The inspectors surveyed each facility thoroughly and kept each other informed as to the results. The surveys were performed with the Micro R meters held at 0.5 meters above the surface with a forward movement of about 1.0 meters per second. In addition to Mr. Smith, who accompanied the inspectors to each site, Mr. Peregoy was present during the surveys of Buildings KC and KJ on the Martin State Airport property.

4.2 Building D

The Building D site was being use to store trailers under contract with the Army. The site consisted of a large concrete pad, the leftover basement floor of the old building. The pad had numerous cracks, holes, and was very weathered after two decades of exposure to the elements.

The inspectors surveyed the concrete pad along parallel lines 5 meters apart, paying attention to drains, clean-outs, and holes in the pad. In addition to measurements taken at drains and clean-outs, surface contact readings were also taken at approximately 10 meter intervals. Numerous sealed/filled in drains/clean-outs/penetrations/holes in the pad were located. Although a few places were found where a hole in the pad had been filled with concrete, it could not be determined if these were any of the drains referred to in the closeout survey. Martin Marietta staff stated that the rubble from the demolition of the building was the responsibility of the contractor and was removed and believed to have been disposed of in a landfill. No detectable radiation levels above background (5μR/hr) were found. No development or other use of the site is planned by Martin Marietta.

4.3 Building C

The Building C area where the old Environmental Test and Large Vacuum Chamber Laboratories were located is now warehouse space and a large empty room. With the exception of the support columns, no original walls, floors, ceiling, or ducts are left. The inspectors surveyed the area along parallel lines at 5 meter intervals with surface contact measurements every 5 meters and at drains and original concrete support columns. No radiation levels above background (5μR/hr) were detected.

4.4 Building KC

Building KC is at the end of a dirt access road off Strawberry Point road just east of the eastern most taxi way. The property was purchased in toto by the State of Maryland in 1975 and although the building was used in the past for storage, it has been abandoned and left open to the elements for the past ten to fifteen years. The site was completely abandoned, overgrown, exposed to the elements (of the three "test cells" only the one where the LFBR had been housed still had it's outer doors). The inspectors performed a walk-through survey of all three cells, the entrance way and connecting halls. Surface contact measurements were performed randomly throughout the building. The office/control room area was not entered due to the cluttered condition of and the layer of asbestos ceiling tiles covering the floor. No radiation levels above background were detected. Although an attempt was made to locate the underground dump/hold-up tank described by Mr. Brisson, the inspectors were unable to locate the tank or any indication that it had been removed. Based on discussion with Martin-Marietta and Martin State Airport personnel, it is believed that the tank was abandoned in place after the decontamination described in Section 2.5. The planning representative of Maryland Aviation stated that the building had been scheduled for demolition after remediation of the asbestos, but the plans were delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

4.5 Building KJ

Building KJ is 300' S.W. of building KC along the dirt access road. The

site was also completely abandoned, overgrown, exposed to the elements. The doors into the laboratory and, mechanical equipment room and office were ajar leaving the interior open to the outside. The inside was littered with "junk", leaves, bird and animal droppings, and dirt. A fair number of 100 lb. bags of "solidified" lime were present, as the building had been use for storage by the State of Maryland in the past. Rusted laboratory furniture and discarded fire extinguishers also littered the floor. The stainless steel ventilation duct-work and the laboratory hoods were still present less the duct-work section that had contained the HEPA filters. The inspectors surveyed the remains as well as possible given the state of the building. No radiation levels above background were detected. The planning representative of Maryland Aviation stated that the building, just like Building KC, had been scheduled for demolition after remediation of the asbestos, but the demolition was delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

5.0 Conclusions

No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

6.0 Exit Interview

The inspector met with the Martin-Marietta and Maryland Department of the Environment representatives listed in Section 1.0 of this report and discussed the scope and findings of this inspection. They acknowledged the inspection findings and the statements documented in this report. Messrs. Flynn and Brisson were contacted by telephone and also confirmed their statements in this report.

NRC Reviewer:	David F. Limroth, Stephen W. Holmes		
Review Abstract:	License No. 19-01389-32 authorized research and development work with unsealed byproduct material in Building D at Middle River, Maryland. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces. The building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on November 3, 1994 indicate that the site is suitable for unrestricted use.		
Recommendations:	None.		

Summary: License No. 19-01398-32 was issued on December 9, 1964 authorizing research and development work with a variety of unsealed byproduct materials in Building D at the Martin Company's Middle River, Maryland facility. On September 4, 1968, License No. 19-01398-32 was transferred to Isotopes, Incorporated. The license was terminated on March 20, 1969; however, no record of a termination or confirmatory survey, transfer of material, etc., could be located. It appears that Building D was returned to Martin-Marietta at that time.

Information from various docket files indicates that a variety of activities with large amounts of byproduct, source, and special nuclear material were authorized at Building D at the Middle River facility. Activities with licensed material at Building D ceased prior to 1970. License No. SNM-1192 was issued to Martin-Marietta on May 22, 1970 and authorized the decontamination of the Martin-Marietta, Middle River, Maryland facility. License No. SNM-1192 has the same Docket No. (70-58) as License No. SNM-53 and all records for License No. SNM-1192 are contained in the docket file for License No. SNM-53. Apparently only Building D was decontaminated under License No. SNM-1192. Building D was decontaminated from June to September 1970 and a final survey report provided to the AEC with a letter dated September 22, 1970. The final survey report states that a total of 29 μCi of U-235 remained in five drains which were to

be were sealed with concrete; one small area of fixed Sr-90 contamination (0.5 mrad/hr) also remained. The building was demolished after the survey, leaving only the concrete pad. Region I staff reviewed the available documentation in 1982 and concluded in Combined Inspection Report Nos. 40-3296/82-01 and 40-2308/82-01 that the site met NRC criteria for unrestricted use.

An NRC site visit and survey was performed on November 3, 1994 to assure that the site meets current NRC guidelines for release for unrestricted use. Buildings C and D at the Middle River facility and Buildings KJ and KC at the Martin State Airport were surveyed. The results of the surveys indicate no radiation or contamination levels above background in any of the buildings surveyed, including the concrete pad remaining from Building D. The contaminated drains discussed in the final survey report regarding Building D were not located, although a number of openings in the pad which had been filled with concrete were identified. Therefore, it seems apparent that the drains identified as contaminated during the final survey were plugged with concrete, as proposed by the licensee. Based on the fact that no radiation or contamination levels above background were detected, it seems unlikely that U-235 contamination in the drains, if present, is a significant hazard. Therefore, the site is suitable for unrestricted use.

USE WAS ON THE APPLICATION FOR 19-01398-14 AND REFERENCED FOR THIS LICENSE.

Reviewer's comments concerning license 19-01398-32

License 19-01398-32 was issued in December,64, to supercede license 19-01398-14 at the Middle River, Md. facility of Martin-Marietta. Yttrium-90 which exists in equilibrium with Sr-90 was not entered as a material and neither was Cm-242 as it has a short halflife and is not available on the expert system. The license was terminated in March,69, by amendment 03 which referenced a licensee letter of 2-3-69. This letter stated a form 314 was attached for disposition of materials, but this form was not found in this file. Since no closeout survey was conducted, the possibility of contamination at the site has not been rule out.

Inquiry Summary:

This inquiry consisted of telephone discussions and review of records provided by Martin-Marietta Corporation and NMSS to determine whether the facility at Middle River, Maryland formerly used for development and production of thorium-magnesium alloys meets current criteria for unrestricted use.

Results: The Middle River (Chesapeake Park) facility meets current criteria for release for unrestricted use.

      Baltimore, Maryland 21201 (301-383-2744)

2. Background

   Martin-Marietta Corporation, Baltimore Division, was authorized by License Nos. C-3991 and STB-187 during the late 1950's and early 1960's for the development and production of magnesium-thorium alloys and for possession and use of small quantities of uranium and thorium metal in connection with work under government contracts. License No. STB-187 expired on April 30, 1964. The authorized place of use was at Martin--Marietta's Middle River, Maryland facilities which are also called Chesapeake Park.

3. Telephone Discussions with Individuals

   Individual A in paragraph 1 was formerly employed as the Health Physics Supervisor at Martin-Marietta and monitored the activities conducted under License Nos. C-3991 and STB-187. He stated that all work authorized by these licenses occurred in the basement of Building D at Chesapeake Park, Middle River, Maryland. Individual D also stated that a former Martin-Marietta employee had told him that Building D had been torn down and the site covered with grass after the building and the site were decontaminated.

   Individual C searched Martin-Marietta records and found a close-out survey covering Building D and correspondence discussing the release of this facility for unrestricted use. He provided the correspondence and survey report in a letter dated June 1, 1982 (see Enclosure A) and confirmed that Building D had been torn down and the area where it stood is now covered with grass.

4. Review of Records

A letter from Martin-Marietta to the AEC dated September 21, 1970 (See Enclosure A) states that AEC License No. SNM-1192 was issued to Martin--Marietta Corporation to allow decontamination of their laboratory facilities and that a report of the decontamination was enclosed. The "Comprehensive Radiation Survey Report for the Release of Decontaminated Premises for Unrestricted Use," enclosed, provided the following points of comparison to the licenses and Individual A's statement:

a. The decontamination effort involved Building D at Chesapeake Park. Individual A stated that all work under License Nos. C-3991 and STB-187 occurred in this building.

b. Special nuclear material processes took place in Building D nuclear laboratories. The decontamination program consisted primarily of removal of U-235 and U-238 residual oxide forms. License No. C-3991 authorized use of uranium metal under government contracts while License No. STB-187 authorized the use of thorium.

Review of the close-out survey indicates that an extensive effort was made to remove all contamination according to AEC criteria and to protect the workers performing the decontamination. Contamination was removed from surfaces by use of high vacuum systems. Fixed contamination found on equipment such as hoods, ducts, glove boxes was allowed to remain fixed and the equipment was removed, properly packaged and shipped to Moorehead Kentucky for burial. Swipe tests were made and various kinds of radiation detectors were used during the decontamination. The report states that removable activities and radiation levels met AEC criteria for release for unrestricted use; however, no site diagram, showing where the swipes and measurements were taken, nor actual results of the measurements are provided.

The report states the average fixed alpha emitter contamination was less than 2000 dpm/100 cm^2, with no beta-gamma contamination, except for a small area of fixed Sr-90 contamination reading 0.5 mrad/hr. Except for the Sr-90 contamination, these results are within present NRC criteria of 5000 dpm/100cm^2 (average U-nat, U-235, U-238 and associated decay products) surface contamination. A fixed contamination level of 0.5 mrad/hr from Sr-90 does not meet the present NRC criteria; however, it is within the 2 mrem/hr limit for an unrestricted area in 10 CFR 20.105(b), and, since it was only a small spot, presented no hazard to personnel.

All water samples taken were stated to be less than or equal to 9.0 x 10^{-7} microcuries per ml compared to 10^{-5} microcuries per ml allowed for U-235 and U-238 in 10 CFR 20, Appendix B, Table II, Column 2. All soil samples were less than 10 pCi per gram U-238 or U-235 except for one sample having 24 pCi per gram of U-238. These results are consistent with the recent Uranium Fuel Licensing Branch position on disposal of uranium.

Residual activity in drains consisted of a total of 29 microcuries of U-235, which the licensee proposed to seal in place with cement.

5. Conclusion

Materials authorized by License Nos. C-3991 and STB-187 were used in Building D at Martin-Marietta's Middle River facilities which are also called Chesapeake Park. The Building D which was decontaminated and released for unrestricted use when AEC License SNM-1192 was terminated is the same facility where work authorized by License Nos. C-3991 and STB-187 was conducted. If any material remained from operations under these licenses it would have been detected and removed during that effort. No determination could be made if the drains containing residual U-235 activity were sealed with cement, however, since the building is now demolished and the site covered with grass this activity is unlikely to present a hazard.

Region I concludes the site meets current NRC criteria for release for unrestricted use and that no site survey is necessary.

Dear Ms. Johansen:

In accordance with your request, I am enclosing, from the records of the Martin Marietta Corporation, a copy of the "Comprehensive Radioactive Survey Report For The Release of Decontaminated Premises For Unrestricted Use", prepared in accordance with U.S.A.E.C. Material License No. SNM-1192 issued to the Martin Marietta Corporation for the decontamination of nuclear laboratories at Baltimore, Maryland.

I am also enclosing a copy of correspondence showing that the Survey Report was furnished to the AEC Division of Materials Licensing at Washington, D.C. and the AEC Compliance Division at Newark, New Jersey. Also, a copy of a letter to the AEC Division of Materials Licensing advising that the decontamination program was near complete and requesting an inspection of the facility.

We are pleased to be able to assist you in this matter.

Very truly yours,

MARTIN MARIETTA CORPORATION

Mr. Donald A. Nussbaumer, Chief
Fuel Fabrication and Transportation Branch
Division of Materials Licensing
United States Atomic Energy Commission
Washington, D.C. 20545

Dear Mr. Nussbaumer:

Please be advised that the decontamination program at the Martin Marietta Corporation Baltimore facilities is nearing completion and it is anticipated the program shall be completed tentatively on August 5, 1970.

We request that an inspection of the subject facility be conducted on August 6, 1970, by a representative of your office in conjunction with the writer and a health physicist from the Eberline Instrument Corporation. If the above date is not compatible with your assignee's schedule and if there are questions regarding the above request and/or program, please advise the writer.

I wish to express my corporation's thanks and appreciation for the excellent service provided by representatives of your office toward bringing this program to a successful completion.

Sincerely yours,

MARTIN MARIETTA CORPORATION

I. INTRODUCTION

Purpose: This radiation survey report is prepared as one of the conditions provided for in U.S.A.E.C. Material License No. SNM-1192 issued to the Martin Marietta Corporation for the decontamination of nuclear laboratories at Baltimore, Maryland.

Since the subject nuclear laboratories are no longer used for radioisotopes operations and/or special nuclear materials processes and have been decontaminated in accordance with U.S.A.E.C. guidelines, it is requested the above named facilities be released for unrestricted use.

On June 3, 1970, the decontamination program at the Martin Marietta Corporation, Baltimore Division, commenced and it was completed on September 2, 1970. The radioactive materials involved in the decontamination program consisted primarily of U^{235} and U^{238} in a residual oxide form.

The work was performed by a crew consisting of 8 trained operators from the Martin Marietta Corporation, two health physicists from Eberline Instrument Corporation, and one health physicist from Martin Marietta Corporation. The removal of the radioactive material from equipment and facilities was achieved primarily through the use of high vacuum systems, with the operators wearing U.S. Bureau of Mines air supplied respirators. Full protective clothing and footwear were provided the workers.

Air samples were collected throughout the general area during the decontamination program and were counted for gross alpha emitters. The results of all air samples collected were below the MPC, with the exception of 4 samples. One sample was collected in the Radioisotopes Laboratory while chipping SR^{90} from a concrete wall. The result was reported as 2.4×10^{-10} uCi/CC. The second sample was collected in the Spheroidizing Room while removing ventilation ducts. The results of the air samples are given in Appendix C-1.

It should be noted that air supply respirators were worn by the operators during the time the air dust concentrations were measured. Urine specimens were submitted by personnel assigned to the program prior to working in the contaminated areas, in order to provide a base line study. Nasal swipes of all men working in the contaminated areas were performed twice daily. The results of all nasal swipes were low to negligible and did show proper use of respiratory protective equipment.

Water samples were collected of all liquid effluent, analyzed prior to release, and records of all sample analysis and personnel dosimetry reports are maintained in the office of the Martin Marietta Corporation's health physicist.

II. LOCATION AND IDENTIFICATION OF FACILITIES

The subject nuclear laboratories that were decontaminated are located at Chesapeake Park and are owned by Martin Marietta Corporation at Baltimore, Maryland. The decontaminated laboratories encompass an area of approximately 40,000 FT^2, located in the basement area of building "D". The total area was subdivided into small separate rooms where various types of nuclear activity were performed. Most of the small rooms were of the laboratory-type, and equipment included ventilation hoods, glove boxes, filtration medias, laboratory benches and laboratory glassware. False ceilings were also a part of some laboratories, and each ceiling was surveyed and removed, where necessary.

For the most part, the radioactivity was confined to glove boxes, ventilation hoods, ducts and filtration medias contained in each laboratory. The radioactive materials removed were in the form of residual uranium oxides, with the exception of a minor amount of SR^{90} found on a wall.

Some of the laboratories contained sinks, floor drains and sumps used to control liquid effluent containing radioactive materials. The floor drains, traps and sumps were carefully monitored to determine the contamination level, if any, and the termination location of each drain line and sump line.

III. HEALTH PHYSICS TECHNICAL APPROACH

The removal of residual contamination was accomplished through the direction and guidance of three health physicists, two from Eberline Instrument Corporation and one from Martin Marietta Corporation. The work crew consisted of eight qualified workers trained in the radiological health aspect of nuclear decontamination.

The contamination, for the most part, was not found to be tightly bonded or sealed to the surfaces of the facilities and therefore most of it was removed by the use of high vacuum systems with absolute filters. One wall and several floor areas showed evidence of bonded alpha activity and, therefore, it became necessary to use pneumatic tools to remove the contamination and reduce radiation levels to acceptable levels. Contamination that was found to be fixed on equipment, such as ventilation hoods, ducts and glove boxes, was allowed to remain fixed, and the equipment was properly packaged, identified and shipped by truck carrier to burial grounds in Moorehead, Kentucky. The transportation and burial of all contaminated equipment was provided by the Nuclear Engineering Company, Moorehead, Kentucky.

IV. SCOPE OF SURVEY AND GENERAL PROCEDURES FOLLOWED

Radiation detection equipment used during the effort included several gas proportional alpha counters, one floor alpha monitor, RM-15 (soft gamma measurement), one beta plus gamma counter, TLD badges and film badge dosimetry.

Swipe samples by the use of whatman filter paper were collected from all surface areas where it was thought to be necessary. The filter paper samples were then counted for any gross alpha contamination. All loose radioactive material was removed from the facilities. Equipment that was heavily contaminated, such as glove boxes and ventilation hoods, were properly packaged and shipped by carrier truck for burial.

There were no areas detected whereby radioactive materials had been sealed by painting or by other means, and there was no attempt to seal any areas containing fixed radioactive materials.

The general procedure followed to accomplish the decontamination effort is entitled "The Health and Safety Procedure for the Decontamination of Building "D", Martin Marietta Corporation, Baltimore, Maryland." The procedure is presently on file in the office of the U.S.A.E.C. Division of Materials Licensing. The procedure provided the basic guidelines for performing the decontamination in a safe manner. "The Guidelines for Decontamination of Facilities and Equipment Prior to Release for Unrestricted Use" was closely adhered to by the Martin Marietta Corporation decontamination work crew.

V. FINDINGS OF THE DECONTAMINATION SURVEY

The floors, walls and ceilings of all laboratories where nuclear activity was conducted were monitored and recleaned. Some areas did not show evidence of contamination. Those areas where contamination was found were vacuumed and sprayed with a jet-x cleaning device to remove any material that could not be vacuumed. The use of water was controlled and kept to a minimum to prevent water contamination and pollution.

During the initial phase of the decontamination inspection survey, six items or areas were found which required correction (letter to E. M. Chenault from S. J. Waligora, Jr., dated September 3, 1970) and all, with the exception of the floor drains, were corrected.

All floor drains were monitored and decontaminated as much as possible. Water samples were taken from the five drains indicating residual activity and all results showed low concentrations. (See Appendix C-2) The residual activity remaining in the six drains was estimated through the use of a 2" x 2" NaI(TR) crystal in conjunction with a single channel analyzer. With the detection system calibrated for ^{235}U gamma rays, the following estimates were established:

Drain No.	^{235}U(uCi)
39	1.0
46	1.0
52	15.0
55	6.0
56	6.0
Total	29.0

Water samples taken from these drains showed very low concentrations. As a further check, water was flushed continuously through these five drains while a two liter water sample was taken from the sanitary sewer sump servicing that portion of the building. Samples were submitted for analysis and showed 0.003 pCi/ml (MPC 30.0 pCi/ml).

All drains have been left open for inspection. With approval from the U.S. Atomic Energy Commission, we propose to seal the five drains with cement, thereby permanently inactivating the total of 29 uCi of ^{235}U. This measure would appear to be a feasible alternative to tearing out the concrete floor in order to remove the drains and associated pipe.

As a result of the final survey, all other areas were reduced to within limits prescribed by the U.S. Atomic Energy Commission. All walls, ceilings, and floors had been washed thoroughly or removed. The average alpha emitter contamination (^{235}U and/or ^{238}U only) is much less than 500 dpm/100 cm^2. Areas with remaining fixed alpha emitter contamination average less than 2,000 dpm/100 cm^2. Beta-gamma contamination is essentially nonexistent; ^{90}Sr-Y contamination which had been present in the Radioisotopes Laboratory has been completely removed with the exception of one minute area with fixed contamination measuring 0.5 mRad/hr.

This area of Building "D" will soon be renovated by Chesapeake Park and any remaining fixed contamination will be further enclosed with replastering, retiling of floors, and repainting. Following the renovation, any fixed residual contamination should be so well fixed that there should be no evidence of even trace quantities during the remaining life of the structure.

VI. PACKAGING, TRANSPORTATION AND DISPOSAL OF CONTAMINATED EQUIPMENT

All contaminated equipment, such as glove boxes, ventilation hoods and duct work, were properly packaged and identified in accordance with the Department of Transportation rules and regulations and sent by truck carrier to Moorehead, Kentucky, for burial. A total of nineteen (19) truckloads of equipment were sent to the burial grounds, with each truckload encompassing approximately 1,920 cubic feet.

APPENDIX B - SUMMARY OF DECONTAMINATION OPERATIONS

The following is a chronological task summary of decontamination operations from June 1 through September 3, 1970, and represents approximately 2400 man hours of labor.

1. Organization of people, equipment, supplies, and facilities; establishment of procedures and policies.
2. Removal of exhaust ducts from furnace room.
3. Samples taken from areas with potential for tritium and for cobalt 60 contamination.
4. Machinery and equipment removed from furnace room.
5. Areas expected to be clean were monitored and any anomalies entered to the work plan.
6. Arrangements were made for special disposal of nonradioactive but hazardous wastes (acids, alkalis, solvents, nitrates, peroxides, etc.)
7. Removed parafin shielding from neutron generator area.
8. Removed equipment from laundry area.
9. Surveyed dehydrator rooms and segregated areas and equipment.
10. Cleaned nine rooms which required general decontamination, but which posed no problems due to presence of contaminated equipment, exhaust ducts, absolute filters, etc.
11. Laundry area cleaned including removal of construction blocks and floor tiles.
12. Cleaned powder room - highly contaminated.
13. Discovered "contamination" in heat plant boiler room which analyses showed to be naturally occurring thorium.
14. Fire (primarily smoke) as the result of torches used during duct removal on outside of building by a local contractor. This duct work was past the absolute filter bands and there was no attendant radiation hazard.

15. General cleaning accomplished in five additional rooms.

16. Vault decontaminated and bird cages removed.

17. Chipped concrete walls contaminated with ^{90}Sr-Y in Radioisotopes Laboratory.

18. Ductwork removal and clean-up in two additional rooms.

19. Removed glove boxes and other contaminated equipment from Spheroidizing Room; proceeded with remainder of clean-up.

20. Removed installed casework in Inorganic Chemistry Laboratory.

21. Decontaminated restroom floors in supposedly clean area.

22. Cleaned contamination which resulted from clean-up of Spheroidization Room.

23. Inspected Oil Farm Building (remote to Building "D") and removed contaminated equipment that had been stored. Survey showed no further decontamination was necessary.

24. Proceeded with clean-up of Inorganic Chemistry Laboratory.

25. Removed ducts and proceeded with clean-up of Powder Metal Room.

26. Removed duct and proceeding with clean-up of three rooms.

27. Removed duct work and equipment in Ceramics Laboratory and Spheroidization Laboratory.

28. Steamed Pellet Room in preparation to clean-up in order to reduce airborne (resuspended) contamination. Proceeded with clean-up.

29. Powder Room was also steamed prior to clean-up.

30. Removed absolute filters associated with Pellet Room.

31. All drains monitored and cleaned. Five remain contaminated.

32. Removed vertical rolling mill (several tons) from Powder Room. Residual contamination forced removal of two walls, ceilings, and floor tiles.

33. Ceiling and floor tiles removed in Spheroidization Room.

34. Removed absolute filters associated with Vault Room.

35. Final blowers, filters and ducts removed at termination and ventilation exhaust equipment.

36. Removed absolute filters and remainder of equipment associated with the Radioisotopes Laboratory.

37. Proceeded throughout entire facility with final monitoring and removed any contaminated items including floor tile, miscellaneous fixtures. Washed down all remaining ceilings, walls, and floors several times. A detailed swipe survey was performed.

38. Sumps and chip tanks associated with Dehydrator, Laundry Room, and Cleaning Room were decontaminated.

39. Asphalt floor covering in Cleaning Room removed.

40. Final waste shipment (19th truckload) departed. Two additional barrels filled with remaining miscellany for future shipment.

Question No. 7 - Describe Purpose for Which Byproduct Material Will Be Used.

E. Includes:

1. Fission products present as impurity in Sr^{90}-Yt^{90} when received.

2. Fission products up to 100 millicuries used to develop methods for separation of Cu-242 from Am-241 and fission products.

3. Irradiated semi-conductors and semi-conductor components. To investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electrical energy.

24501

9. Experience with Rad ion (Actual use of radioiso. es or equivalent experience)

	Isotope	Maximum Amount	Where Experience Was Gained	Duration of Experience	Type
A.	C^{14}	Curie Quant.	Brookhaven Nat'l. Lab.	1 yr.	Research
B.	I^{131}		" "	3 yrs.	Research & process dev.
C.	Ce; R.E. Xe, Po	Several Curies	" "	4 yrs. 4 yrs. 2 yrs.	Analysis of solutions from LMFR

EXPERIENCE WITH RADIATION:

Work was done on a small research project to determine maximum concentration of titanium formed in fission. A procedure was developed for decontamination of titanium from other fission products and the investigation was successfully concluded. Several curies of mixed fission products were involved.

A. A one year research program on isotopic exchange between Co_2 of the atmosphere and C^{14} from $BuCO_3$ was also successfully undertaken using tracer quantities.

B. A great deal of work was done with iodine 131 during the development of a device for "milking" I^{131} from Te^{131} for cancer research. This program later changed to Te^{132}. A device was developed and a patent applied for. This device enables a user of short lived I^{132} to have this material constantly available by milking a chromotographic column on which is embedded Te^{132}.

C. With the advent of the LMFR research program at Brookhaven, extensive analytical work was done on corrosion samples from the radiation loop, analyzing for such elements as radioactive iodine, tellurium, cerium, cesium, ruthenium, strontium, rare earths and Xenon. A procedure was developed for the separation of Xenon from metal samples and analysis of it s quantity. This work later was extended to samples from reactor irradiated bismuth which contained much polonium. Separation procedures were developed for removing polonium from all samples and also for removing bismuth from samples in which bismuth interferred. Uranium was also separated and analyzed for. Total activity per sample was almost 1 curie.

In addition to the above experience Mr. Samos has conducted the work in the Radioisotope Laboratory of The Martin Company under the direction of Mr. H. O. Banks since January 1959.

SUPPLEMENTAL SHEET NO. 2

24901

Question No. 10 - Radiation Detection Instruments

Type of Instrument	No. Avail.	Radiation Detected	Sensitivity Range	Window Thickness	Use
GM Survey, Nuclear Chicago Md 2612	6	Beta, gamma	0-60,000 c/m 0-20 mr/hr	35 mg/cm^2	Monitoring Surveying
Gas Flow Proportional Counter NMC Md PC-1A	2	Alpha, Beta-gamma	0.5-1,000,000 d/m; 100-1,000,000 d/m	gas chamber	Measuring
Gas Proportional Alpha Counter Eberline Instr. PAC-36	2	Alpha	0-100,000 c/m	0.85 mg/cm^2	Monitoring Surveying
Alpha Scintillation NRD Md-CS-5 + Md S5-A Basic Scintillation Unit	1	Alpha	-	-	Measuring
Alpha, Beta, Gamma Air Particulate Monitor NMC Model AM 33	1	Alpha Beta Gamma	10^{-12} uc/cc Alpha or Beta Gamma	gas prop. detector	Monitoring measuring

Question No. 11 - Method, Frequency, and Standards Used In Calibrating Instruments Listed Above (Question 10)

Calibration of Health Physics survey instruments is performed in the Calibration Facility located in the Waste Storage Room outside the Nuclear Manufacturing and Engineering Laboratories at Plant No. 1. Each instrument is calibrated once a month. Repaired instruments are calibrated when they are returned to Health Physics.

The sources are located in one corner of the Waste Room behind a four foot high, eight-inch thick, cement block wall. A one curie Co-60 source contained in a lead-steel shielded container is used for calibrating "Cutie-Pie" and similar type instruments.

The source is calibrated so that at given distances the dose rate in mr/hr is known. The instrument can be remotely placed at a given distance from the source and calibrated to read the field of radiation at that distance. Where possible, each instrument is calibrated on each scale or range setting.

Smaller Sources include an eight millicurie Co-60 source and a one millicurie Ra-226 source. These are also stored behind the shielding wall and used to calibrate low range (up to 20 mr/hr) instruments.

Neutron survey instruments are calibrated by using a five curie Po-Be neutron source of known flux (determined by foil activation) and setting the instrument to read the correct level.

Counting room instruments are calibrated by using standard calibrated sources of uranium alpha and beta-gamma. The first step is construction of a "plateau" to determine correct operating voltages. The counter efficiency is then determined by comparing the counter countrate with that of the standard source.

The NMC Model AM 33 Alpha-Beta-Gamma Air Particulate Monitor is calibrated by placing a source of known disintegration rate in view of the detector. The source used is the isotope in process at that time. The monitor is calibrated according to the disintegration rate and air flow necessary to match the calibration source.

The Eberline PAC-3G Gas Proportional Alpha Counter is calibrated by placing alpha sources of known disintegration rate in front of the probe face. Check sources and counting plateaus are provided for high voltage adjustments which are necessary with altitude changes.

24901

Question No. 12 - Film Badges, Dosimeters, and Bio-Assay Procedures Used.

A. General:

All personnel working with radioactive materials permanently or temporarily, are required to wear a film badge and two pocket chambers sensitive to beta-gamma radiation.

Personnel working in areas where fast and/or thermal neutron radiation is prevalent are required to wear a film badge sensitive to beta, gamma and fast neutrons and pocket chambers sensitive to thermal neutrons.

Film badges are changed either weekly, biweekly, or each 13 weeks depending upon the radiation levels in the work areas. Pocket chambers are changed and read daily. Self-reading dosimeters are also available and used under the discretion of Health Physics.

A film badge service is contracted on a yearly basis to supply and process film and badges for the program. The present supplier is Health Physics Services, Baltimore, Maryland

B. Dosimetry Information:

Special film badge changes are made by Health Physics when any of the following conditions exist:

(1) Both pocket chambers off scale.

(2) Exposure in excess of 100 mr/wk is recorded from daily pocket chamber readings.

(3) Inexplicable exposure in excess of 50 mr per day is recorded.

Permanent records are maintained of all film badge and pocket chamber results.

The upper limit of dosimetry response is as follows:

FILM BADGES	UPPER LIMIT (rem)
Gamma	1000
Beta	500
Neutrons	100
POCKET CHAMBERS	
Gamma	200 mr
Neutrons	200 mrem

(Question No. 12 - Cont'd.)

C. Bioassay

All facility personnel are required to submit bioassay samples at periodic intervals. In the case of unusual incidents, including exposure to airborne concentrations of radioactive materials exceeding the maximum permissible concentrations for personnel without respiratory protection, or other suspected ingestion of radioactive material, special samples are collected from all personnel involved.

All urinalysis results are filed as permanent records in the Health Physics office and are available to responsible persons upon request.

24301

Question No. 14 - Radiation Protection Program

A. Health Physics Responsibilities:

1. Plans and administers the radiation protection program to provide adequate protection to Company and to personnel from ionizing radiation.

2. The inspection and monitoring, with the aid of various detection instruments, of personnel, machinery, furniture, ventilating equipment, gamma and neutron irradiation test facilities, radioisotopic laboratories, etc., to detect and prevent spread of radioactivity, measure levels of radiation or concentrations of radioactive materials present.

3. The review and approval of all working areas and facilities.

4. The evaluation of radiation hazard control methods for adequacy and compliance with recommendations of the National Committee on Radiation Hazards and pertinent government regulations.

5. The promotion of the Health Physics program through the proper indoctrination and training of personnel engaged in handling or working with materials or equipment that emit ionizing radiation.

6. Determines radiation monitoring equipment requirements in all areas.

7. The internal control and enforcement of licensing regulations pertaining to receiving, possession, use, transfer and disposal of nuclear source, special nuclear, or by-product materials.

8. The investigation of accidents and personnel radiation exposures to determine the cause and recommend corrective action to be taken to eliminate future occurrences.

9. The continual monitoring of personnel engaged in handling or working with radioactive materials and x-ray equipment for compliance with recommended procedures and regulations of good housekeeping and work habits.

10. The issuance of appropriate personnel monitoring devices (film badges, pocket chambers, etc.), scheduling of pre-exposure and follow-up physical examination, and the establishment and maintenance of detailed employee records of cumulative doses of radiation exposure, biological assays, laboratory reports, etc., to form the basis of permanent Company records and to conform to Atomic Energy Commission regulations.

11. The conducting of laboratory tests of environmental sample analyses and biological assays to determine the quantity of radioactivity discharged to the environs and the quantity received by the individual through inhalation, ingestion, wounds, etc.

24901

Question 14 - Cont'd.

12. Collaborates with representatives of the various divisions and departments concerned on reactor site surveys, design of facilities, power reactors and associated control systems for hazard evaluation and control to assure protection of personnel and facilities.

13. Maintains liaison with representatives of the Atomic Energy Commission, National Committee on Radiation Hazards, Federal, State and Local government health and welfare agencies, and various divisions and departments, to resolve areas of common health physics interest.

14. Prepares and revises as necessary Health Physics bulletins outlining procedures to be followed to assure compliance with all pertinent National Committee or radiation hazards recommendations and government regulations.

15. The calibration of all Health Physics monitoring instruments where radiation sources must be used to perform the calibration.

B. Leak Testing

Leak tests are performed on all sealed sources when they are received and at least once every three months thereafter. The source, or source shield, depending upon the strength of the source, is wiped with a filter paper disc. The disc is then counted in the proper radiation counter to detect and measure any leakage of alpha or beta-gamma contamination.

Radium sources are leak tested by wrapping the source in cotton for approximately three days, removing the cotton and counting it with a beta-gamma detector.

Leak tests are performed by Health Physics techniciane who have had three years of on-the-job Health Physics training with The Martin Company.

Maintenance, service and repairs to all sources are performed by the source supplier.

C. See also supplementary report MND 2109.

24901

Question No. 15 - Waste Disposal

Solid waste is currently stored in 55 gallon steel drums awaiting disposal through an AEC approved, licensed waste disposal service. A record is maintained by Health Physics concerning the contents, radiation and number of each drum.

Liquid waste is monitored to assure that the levels of radioactivity are below the tolerances established in Title 10, Part 20 Code of Federal Regulations for disposal into sanitary sewers. All liquid waste with activity above those levels is evaporated and concentrated for eventual solid waste disposal through AEC approved and licensed waste disposal services.

24901

Question No. 13 - Facilities and Equipment

The Radioisotopes Laboratory consists of 3 sections - a small office area, a general lab for doing cold chemistry and tracer level chemistry, and a large room 22 ft. square which is being set up as a warm chemistry lab.

The general lab has a main lab bench, several tables, counting equipment and a hood. The air flow through the hood, with the door half way down is 100 l.f.m. An absolute type filter is in the line to absorb all particulate matter. The interior of the hood is of stainless steel, top, sides and bottom. Work involving use of trace quantities of isotopes is done in the hood. The floor of the hood is covered with "kimpak", an absorbent paper, and this is covered with polyethylene sheeting to facilitate decontamination, if a spill should occur. Liquid radioactive waste is kept in a 5 gallon polyethylene bottle. Metal pails with polyethylene bag liners are used for solid waste. A bench monitor is used to survey glassware, hands and clothing for β contamination. Portable gas flow proportional counters will be used for γ monitoring.

The large area, a room approximately 22' X 22' is currently being prepared for alpha chemistry work. The room has 2 foot thick concrete walls. A fiber glass polyester resin floor has been laid over the existing concrete floor to facilitate decontamination should a spill occur. A 6" thick steel door, on rollers, is located in the outside wall of the room to enable large pieces of equipment to be brought into the room. This room has been used for gamma radiography and the heavy steel door served as a radiation shield. The doorway will be altered so that two regular doors can be installed. The steel door will then be left normally open unless the radiation level will be such as to make closing necessary.

Americium, curium and plutonium chemistry will be done in glove type dry boxes. Each box is 27" deep, 26" long and 30" high with sloping safety glass fronts incorporating 8" fiberglass gloves. The box will be made of plastic sandwich honeycomb with coved corners, 1/8" thick stainless steel floor, and safety plate glass mounted in interlock rubber retainer. Filters are two replaceable Pf 105 inlet and one combination pre-filter Cambridge absolute type filter rated for 50 cfm, at 1" H_2O. A fluorescent light fixture and four liquid line fittings are also provided. All plastic materials are fire and chemical resistant. The box has 7" X 8" access ports at each end of the box which open inward and lock shut against neoprene gaskets to seal the chamber.

U. S. ATOMIC ENERGY COMMISSION
BYPRODUCT MATERIAL LIC. SE

Pursuant to the Atomic Energy Act of 1954 and Title 10, Code of Federal Regulations, Chapter 1, Part 30, Licensing of Byproduct Material, and in reliance on statements and representations heretofore made by the licensee, a license is hereby issued authorizing the licensee to receive, acquire, own, possess, transfer and import byproduct material listed below; and to use such byproduct material for the purpose(s) and at the place(s) designated below. This license shall be deemed to contain the conditions specified in Section 183 of the Atomic Energy Act of 1954, and is subject to all applicable rules, regulations, and orders of the Atomic Energy Commission now or hereafter in effect and to any conditions specified below.

Licensee	
1. Name: Martin-Marietta Corporation, Nuclear Division	3. License number: 19-1398-32 (166)
2. Address: Baltimore 3, Maryland	4. Expiration date: December 31, 1966
	5. Reference No.: 19-1398-14

6. Byproduct material (element and mass number)	7. Chemical and/or physical form	8. Maximum amount of radioactivity which licensee may possess at any one time
A. Strontium 90-Yttrium 90	A. Any	A. 100 curies
B. Cesium 137	B. Any	B. 1 curie
C. Americium 241 (see page 2)	C. Any	C. 25 millicuries

9. Authorized use

A. To be used to develop methods of purification and to test corrosion of fuel form compounds
B. and F. To be used to investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electrical energy.
C., D. and E. To be used to develop methods for separation of Curium 242 from Americium 241 and fission products. (see page two)

CONDITIONS

10. Unless otherwise specified, the authorized place of use is the licensee's address stated in Item 2 above:

11. Byproduct material may only be used at Martin-Marietta Corporation, Middle River Plant, Middle River, Maryland.

12. The licensee shall comply with the provisions of Title 10, Part 20, Code of Federal Regulations, Chapter 1, "Standards for Protection Against Radiation".

13. Byproduct material shall be used by, or under the supervision of, George Samos, James C Neace, or John H. Gray.

14. A. Each sealed source acquired from another person and containing byproduct material with a half-life greater than thirty days and in any form other than gas, shall be tested for contamination and/or leakage prior to use. In the absence of a certificate from a transferor indicating that a test has been made within six months prior to the transfer, the sealed source shall not be put into use until tested.
(see page two)

MATERIAL LICENSE

Supplementary Sheet

Continued From Page 1

License Number 19-1398-32
(166)

6. Byproduct material (element and mass number)	7. Chemical and/or physical form	8. Maximum amount of radioactivity which licensee may possess at any one time
D. Curium 242	D. Any	D. 20 millicuries
E. Any byproduct material between Atom Nos. 3 & 83, inclusive	E. Irradiated semiconductors, semiconductor components and/or mixed fission products	E. 20 curies
F. Promethium 147	F. Any	F. 65 curies
G. Europium 152	G. Any	G. 3 millicuries
H. Europium 154	H. Any	H. 3 millicuries
I. Any byproduct material having Atomic Nos. between 3 & 83, inclusive	I. Any	I. 25 millicuries

9. Authorized Use (Continued)

G. and H. To be used in development of chemical processes for purification of rare earths.
I. Transportation of material between facilities of the licensee at Middle River, Maryland and the University of Maryland for the measurement of tracer amounts of radioisotopes in irradiated material.

Condition 14 continued:

B. Each sealed source fabricated by the licensee shall be tested for contamination and/or leakage immediately after fabrication. If the test reveals the presence of 0.005 microcurie or more of removable contamination, the licensee shall repair and/or decontaminate and retest the source. Sealed sources fabricated for distribution and containing byproduct material (with the exception of solid metallic Iridium 192, byproduct material with a half-life not exceeding thirty days, and byproduct material in the form of gas) shall, in addition to an initial test upon fabrication, be stored for a period of seven days and retested prior to being distributed.

C. Each sealed source containing byproduct material with a half-life greater than thirty days and in any form other than gas, shall be tested for leakage and/or contamination at intervals not to exceed six months, except that sources designed as an alpha emitting source shall be tested at intervals not exceeding three months

(... next page)

Item 14 continued:

The test shall be capable of detecting the presence of 0.005 microcurie of removable contamination on the test sample. The test sample shall be taken from the sealed source or from the appropriate accessible surfaces of the device in which the sealed source is permanently or semipermanently mounted or stored. Records of leak test results shall be kept in units of microcuries and maintained for inspection by the Commission.

If the test required in A or C above reveals the presence of 0.005 microcurie or more of removable contamination, the licensee shall immediately withdraw the sealed source from use and shall cause it to be decontaminated and repaired or to be disposed of in accordance with Commission regulations. A report shall be filed within five days of the test with the Director Division of Materials Licensing, U. S Atomic Energy Commission, Washington, D. C., 20545, describing the equipment involved, the test results, and the corrective action taken. A copy of such report shall be sent to the Director, Region I, Division of Compliance, USAEC, 376 Hudson Street, New York, New York, 10014.

Except as provided otherwise by this license, the licensee shall possess and use byproduct material described in Items 6, 7 and 8 of this license in accordance with statements, representations, and procedures contained in the application for license, amendments thereto if any, submitted by the licensee's predecessor, the Martin Company; application from the Martin Marietta Corporation dated September 28, 1962; letter from the Martin Company dated October 10, 1961; letter from Martin Marietta Corporation dated October 17, 1961; letter from Richard H. Boutelle dated May 3, 1962; letter from C W Keller dated November 25 1964.

1. Name: Martin - Marietta Corporation Isotopic Power Development	3. License number: 19-1398-14 is amended in its entirety to read as follows:
2. Address: Department of Nuclear Division Baltimore 3, Maryland	4. Expiration date: October 31, 1962
	5. Reference No.

6. Byproduct material (element and mass number)	7. Chemical and/or physical form	8. Maximum amount of radioactivity which licensee may posses at any one time
A. Strontium 90-Yttrium 90	A. Any	A. 100 curies
B. Cesium 137	B. Any	B. 1 curie
(See Page 2)		

9. Authorized use

A. To be used to develop methods of purification and to test corrosion of fuel form compounds.

B. and F. To be used to investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electrical energy.

(See Page 2)

CONDITIONS

10. Unless otherwise specified, the authorized place of use is the licensee's address stated in Item 2 above.

11. Byproduct material may only be used at Martin-Marietta Corporation, Middle River Plant, Middle River, Maryland.

12. The licensee shall comply with the provisions of Title 10, Part 20, Code of Federal Regulations, Chapter 1, "Standards For Protection Against Radiation".

13. Byproduct material shall be used by, or under the direct personal supervision of, George Sanso, Edward Fowler or Arnold Abries.

14. A. Each sealed source acquired from another person and containing byproduct material with a half-life greater than thirty days and in any form other than gas, shall be tested for contamination and/or leakage prior to use. In the absence of a certificate from a transferor indicating that a test has been made within six months prior to the transfer, the sealed source shall not be put into use until tested.

(See Page 2)

6. Byproduct material (element and mass number)	7. Chemical and/or physical form	8. Maximum amount of radioactivity which licensee may possess at any one time
C. Americium 241	C. Any	C. 25 millicuries
D. Curium 242	D. Any	D. 20 millicuries
E. Any byproduct material between Atomic Nos. 3 and 83, inclusive	E. Irradiated semiconductors, semiconductor components and/or mixed fission products	E. 20 curies
F. Promethium 147	F. Any	F. 65 curies
G. Europium 152	G. Any	G. 3 millicuries
H. Europium 154	H. Any	H. 3 millicuries

9. Authorized use

C., D. and E. To be used to develop methods for separation of Curium 242 from Americium 241 and fission products.

G. and H. To be used in development of chemical processes for purification of rare earths.

CONDITIONS

14. B. Each sealed source fabricated by the licensee shall be tested for contamination and/or leakage immediately after fabrication. If the test reveals the presence of 0.005 microcurie or more of removable contamination, the licensee shall repair and/or decontaminate and retest the source. Sealed sources fabricated for distribution and containing byproduct material (with the exception of solid metallic Iridium 192, byproduct material with a half-life not exceeding thirty days, and byproduct material in the form of gas) shall, in addition to an initial test upon fabrication, be stored for a period of seven days and retested prior to being distributed.

C. Each sealed source containing byproduct material with a half-life greater than thirty days and in any form other than gas, shall be tested for leakage and/or contamination at intervals not to exceed six months, except that sources designed as an alpha emitting source shall be tested at intervals not exceeding three months.

(See Page 3)

d From Page 2

CONDITIONS

Each sealed source containing byproduct material with a half-life greater than thirty days and in any form other than gas, shall be tested for leakage and/or contamination at intervals not to exceed six months, except that sources designed as an alpha emitting source shall be tested at intervals not exceeding three months.

The test shall be capable of detecting the presence of 0.005 microcurie of removable contamination on the test sample. The test sample shall be taken from the sealed source or from appropriate accessible surfaces of the device in which the sealed source is permanently or semipermanently mounted or stored. Records of leak test results shall be kept in units of microcuries and maintained for inspection by the Commission.

If the test required in A or C above reveals the presence of 0.005 microcurie or more of removable contamination, the licensee shall immediately withdraw the sealed source from use and shall cause it to be decontaminated and repaired or to be disposed of in accordance with Commission regulations. A report shall be filed within five days of the test with the Director, Division of Licensing and Regulation, U. S. Atomic Energy Commission, Washington 25, D. C., describing the equipment involved, the test results and the corrective action taken. A copy of such report shall be sent to the manager of the nearest AEC operations office listed in Appendix D of Title 10, Code of Federal Regulations, Part 20.

ept as provided otherwise by this license, the licensee shall possess and use roduct material described in Items 4, 7 and 8 of this license in accordance h statements, representations and procedures contained in the application for ense, and amendments thereto if any, submitted by the licensee's predecessor, Martin Company, letter from the Martin Company dated October 10, 1961 and ter from Martin-Marietta Corporation dated October 17, 1961.

FORM AEC-374
(12-57)

U. S. ATOMIC ENERGY COMMISSION

BYPRODUCT MATERIAL LICENSE NO. 19-1393-14, AMENDMENT (362) NO. 6

Pursuant to the Atomic Energy Act of 1954 and Title 10, Code of Federal Regulations, Chapter 1, Part 30, Licensing of Byproduct Material, and in reliance on statements and representations heretofore made by the licensee, a license is hereby issued authorizing the licensee to receive, acquire, own, possess, transfer and import byproduct material listed below; and to use such byproduct material for the purpose(s) and at the place(s) designated below. This license shall be deemed to contain the conditions specified in Section 183 of the Atomic Energy Act of 1954, and is subject to all applicable rules, regulations, and orders of the Atomic Energy Commission now or hereafter in effect and to any conditions specified below.

Licensee	
1. Name: The Martin Company Isotopic Power Development	3. License number: In accordance with application dated September 27, 196 19-1393-14 is amended in its entirety to read as follows:
2. Address: Department of Nuclear Division Baltimore 3, Maryland	4. Expiration date: October 31, 1962
	5. Reference No.

6. Byproduct material (element and mass number)	7. Chemical and/or physical form	8. Maximum amount of radioactivity which licensee may posses at any one time
A. Strontium 90 - Yttrium 90	A. Any	A. 155 curies
B. Cesium 137 (See Page 2)	B. Any (See Page 2)	B. 1 curie (See Page 2)

9. Authorized use

A. To be used to develop methods of purification and to test corrosion of fuel form compounds.

(See Page 2)

CONDITIONS

10. Unless otherwise specified, the authorized place of use is the licensee's address stated in Item 2 above.

11. Byproduct material may only be used at Martin Plant, Middle River, Maryland.

12. The licensee shall comply with the provisions of Title 10, Part 20, Code of Federal Regulations, Chapter 1, "Standards for Protection Against Radiation."

13. Byproduct material shall be used by, or under the direct supervision of, George Semos, Edward Fowler or Arnold Airing.

14. A Each sealed source, acquired from another person, containing byproduct material with a half-life greater than thirty (30) days and in any form other than gas, shall be tested for leakage and/or contamination. The test shall be performed on the sealed source surface, or on the accessible surfaces of the device in which such a source is permanently or semi-permanently mounted. The test shall be performed upon receipt from another person, unless the licensee receives certification from the person making the transfer that the sealed source had been tested within thirty (30) days prior to transfer and found free of any removable radioactive material. (See Page 2)

CONTINUED:

6. Byproduct material (element and mass number)	7. Chemical and/or physical form	8. Maximum amount of radioactivity which licensee may possess at any one time
C. Americium 241	C. Any	C. 25 millicuries
D. Curium 242	D. Any	D. 20 millicuries
E. Any byproduct material between Atomic Nos. 3 and 83, inclusive	E. Irradiated semiconductors, semiconductor components and/or mixed fission products	E. 20 curies
F. Promethium 147	F. Any	F. 63 curies

9. Authorized use

B and F. To be used to investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electrical energy.

C, D and E. To be used to develop methods for separation of Curium 242 from Americium 241 and fission products.

CONDITIONS

14. continued

B Each sealed source containing byproduct material which is fabricated by the licensee shall be tested for leakage and/or contamination immediately after fabrication. If the test reveals any removable radioactive material, the licensee shall repair and/or decontaminate and retest the source prior to placing it in use.

C Following completion of the test prescribed in A or B, each sealed source containing byproduct material with a half-life greater than thirty (30) days and in any form other than gas, except sources designed as alpha emitting sources, shall be tested for leakage and/or contamination at intervals not to exceed six (6) months. Each sealed source which is designed as an alpha emitting source shall be tested at intervals not to exceed three (3) months.

(See Page 3)

Supplementary Sheet

License Number 19-1393-14 (302)

AMENDMENT NO. 6

D:

CONDITIONS

ntinued

The test performed pursuant to A, B, or C shall be sufficiently sensitive to detect 0.05 microcurie of removable beta and/or gamma emitting radioactive material and 0.005 microcurie of removable alpha emitting radioactive material. Records of leak test results shall be maintained by the licensee.

If the test performed pursuant to A or C reveals removable radioactive material, the licensee shall take immediate action to prevent spread of contamination and shall notify the Isotopes Branch, Division of Licensing and Regulation, U. S. Atomic Energy Commission, Washington 25, D. C. within thirty (30) days after completion of the test.

cept as provided otherwise by this license, the licensee shall possess and byproduct material described in Items 6, 7 and 8 of this license in ordance with statements, representations, and procedures contained in his lications dated February 5, 1959, March 11, 1960 and September 27, 1960.

suant to the Atomic Energy Act of 1954 and Title 10, Code of Federal Regulations, pter 1, Part 70, "Special Nuclear Material Regulations," you are further ensed to receive, possess and use special nuclear material resulting from the ay of Americium 241 and Curium 242. This license shall be deemed to contain conditions specified in Section 70.32 (a) of said regulations.

Gentlemen:

We have recently completed a review concerning our need for the subject licenses. As a result of this review, we are requesting the following actions:

(1) Termination of BPML No. 19-01398-32
AEC Form 314 attached.

(2) Renewal and amendment of BPML No. 19-01398-01
AEC Form 313 and Supplemental Data to support our request attached. The supplemental data was prepared to conform with the request contained in referenced correspondence.

This new information is being furnished to support our amended request. Except for those specific references contained herein, it is intended that this information supersede all previous submittals made in connection with BPML No. 19-01398-01.

Sincerely,

Peter J. Knapp

Attention: Mr. Peter J. Knapp
Licensing and Accountability
Representative

Gentlemen:

This will confirm your telephone conversation of January 3, 1969, with Mr. Robert J. Dube.

In support of your application for renewal of License Nos. 19-01398-32 and 19-01398-01, please complete items 10 through 15 of Form AEC-313. You should include an updated comprehensive description of the administrative and operational aspects of your radiation safety program. Information previously submitted describing your facilities and equipment may be incorporated in your application by specific reference including date of the letter or application containing the information.

Sincerely,

Original Signed by
Robert E. Brinkman

Form AEC-313 (8-64) 10 CFR 30

UNITED STATES ATOMIC ENERGY COMMISSION

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved. Budget Bureau No. 38-R027

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application or an application for renewal of a license. Information contained in previous applications filed with the Commission with respect to Items 8 through 15 may be incorporated by reference provided references are clear and specific. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail two copies to: U.S. Atomic Energy Commission, Washington, D.C., 20545, Attention: Isotopes Branch, Division of Materials Licensing. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30, and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital person, etc. Include ZIP Code.)*

Isotopes, a Teledyne Company
Nuclear Systems Division
P. O. Box 4937
Eastern Blvd. at Martin Blvd. N.E.
Middle River, Maryland 21220

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1(a). Include ZIP Code.)*

Same

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Nuclear Systems Division

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

19-01398-32

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

John H. Gray

5. RADIATION PROTECTION OFFICER. *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Richard Brisson

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*	(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*	
A. Strontium 90-Yttrium 90	A. Any	A. 100 curies
B. Cesium 137	B. Any	B. 1 curie
C. Americium 241	C. Any	C. 25 millicuries
D. Curium 242	D. Any	D. 20 millicuries
E. Any byproduct material between Atomic Nos. 3&83 inclusive	E. Irradiated semiconductors semiconductor components and/or mixed fission products	E. 20 curies
F. Promethium 147	F. Any	F. 65 curies
G. Europium 152	G. Any	G. 3 millicuries
H. Europium 154	H. Any	H. 3 millicuries
I. Any byproduct mat'l having Atomic Nos. between 3& 83 Inclusive	I. Any	I. 25 millicuries

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

A. To be used to develop methods of purification and to test corrosion of fuel form compounds

B. and F. To be used to investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electric energy.

C., D. & E. To be used to develop methods for separation of Curium 242 from Americium 241 and fission products.

G. and H. To be used in development of chemical processes for purification of rare earths.

I. Transportation of material between facilities of the licensee at Middle River, Maryland and the University of Maryland for the measurement of tracer amounts of radioisotopes in irradiated material.

06763

(Continued on reverse side)

TRAINING AND EXPERIENCE OF EACH INDIVIDUAL NAMED IN ITEM 4 *(Use supplemental sheets if necessary)*

8. TYPE OF TRAINING	WHERE TRAINED	DURATION OF TRAINING	ON THE JOB *(Circle answer)*	FORMAL COURSE *(Circle answer)*
a. Principles and practices of radiation protection	See last previous application		Yes No	Yes No
b. Radioactivity measurement standardization and monitoring techniques and instruments			Yes No	Yes No
c. Mathematics and calculations basic to the use and measurement of radioactivity			Yes No	Yes No
d. Biological effects of radiation			Yes No	Yes No

9. EXPERIENCE WITH RADIATION. *(Actual use of radioisotopes or equivalent experience.)*

ISOTOPE	MAXIMUM AMOUNT	WHERE EXPERIENCE WAS GAINED	DURATION OF EXPERIENCE	TYPE OF USE
		See last previous application		

10. RADIATION DETECTION INSTRUMENTS. *(Use supplemental sheets if necessary.)*

TYPE OF INSTRUMENTS *(Include make and model number of each)*	NUMBER AVAILABLE	RADIATION DETECTED	SENSITIVITY RANGE *(mr/hr)*	WINDOW THICKNESS *(mg/cm²)*	USE *(Monitoring, surveying, measuring)*
See last previous application					

11. METHOD, FREQUENCY, AND STANDARDS USED IN CALIBRATING INSTRUMENTS LISTED ABOVE.

See last previous application

12. FILM BADGES, DOSIMETERS, AND BIO-ASSAY PROCEDURES USED. *(For film badges, specify method of calibrating and processing, or name of supplier.)*

See last previous application

INFORMATION TO BE SUBMITTED ON ADDITIONAL SHEETS IN DUPLICATE

13. FACILITIES AND EQUIPMENT. Describe laboratory facilities and remote handling equipment, storage containers, shielding, fume hoods, etc. Explanatory sketch of facility is attached. *(Circle answer)* Yes No

See last previous application

14. RADIATION PROTECTION PROGRAM. Describe the radiation protection program including control measures. If application covers sealed sources, submit leak testing procedures where applicable, name, training, and experience of person to perform leak tests, and arrangements for performing initial radiation survey, servicing, maintenance and repair of the source.

See last previous application

15. WASTE DISPOSAL. If a commercial waste disposal service is employed, specify name of company. Otherwise, submit detailed description of methods which will be used for disposing of radioactive wastes and estimates of the type and amount of activity involved.

See last previous application

CERTIFICATE (This item must be completed by applicant)

16. THE APPLICANT AND ANY OFFICIAL EXECUTING THIS CERTIFICATE ON BEHALF OF THE APPLICANT NAMED IN ITEM 1, CERTIFY THAT THIS APPLICATION IS PREPARED IN CONFORMITY WITH TITLE 10, CODE OF FEDERAL REGULATIONS, PART 30, AND THAT ALL INFORMATION CONTAINED HEREIN, INCLUDING ANY SUPPLEMENTS ATTACHED HERETO, IS TRUE AND CORRECT TO THE BEST OF OUR KNOWLEDGE AND BELIEF.

Attention: Mr. John McBride, Director

Subject: Transfer of Byproduct License Responsibility

Reference: (a) Title 10 Code of Federal Regulations, Part 30.34b

Gentlemen:

Effective August 4, 1968, Isotopes, Inc., A Teledyne Company, 50 Van Buren Place, Westwood, New Jersey 07675 assumed responsibility for the Nuclear Division of the Martin Marietta Corporation located in Middle River, Maryland. In compliance with reference (a), Isotopes, Inc. hereby requests the consent of the USAEC for the transfer to Isotopes, Inc. of the Martin Marietta Corporation Byproduct Licenses listed on the attachment to this letter.

Until further notice, Isotopes, Inc. will continue to operate in the same facilities in Middle River, Maryland as the Nuclear Systems Division of Isotopes, Inc.

Isotopes, Inc. affirms that in accepting the transfer of these licenses we adopt the statements, representations, and procedures contained in the applications and correspondence filed by the Martin Marietta Corporation and identified in the licenses and any amendments thereof listed in the attachment to this letter.

Very truly yours,

ISOTOPES, INC.

Gentlemen:

Isotopes, Inc., A Teledyne Company, has acquired the Martin Marietta Corporation Nuclear Division effective August 4, 1968. We are aware that Isotopes, Inc. is in the process of filing an application for the transfer of Byproducts Licenses as enumerated on the attached enclosure, which request will be submitted during the week of August 5, 1968.

The Martin Marietta Corporation consents to the transfer of the above mentioned licenses and joins Isotopes, Inc. in its request for said transfer.

Very truly yours,

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved
Budget Bureau No. 38-R027.4

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail three copies to: U. S. Atomic Energy Commission, Washington 25, D. C. Attention: Isotopes Branch, Division of Licensing and Regulation. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30 and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital, person, etc.)*

The Martin Company
Nuclear Division
Baltimore 3, Md.

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1 (a).)*

Middle River Plant
Middle River, Maryland

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Auxilliary Power Systems Department
(Formerly Isotopic Power Development Department

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

Amendment to 19-1398-14

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

George Samos
Edward Fowler
Arnold Abross

5. RADIATION PROTECTION OFFICER *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Richard H. Boutelle

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*

Eu 152-154

(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*

Any chemical form 3 mc maximum

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

To be used as a tracer in the laboratory development of chemical processes for purification of rare earths.

Subject: Renewal of Martin Marietta Byproduct Material License No. 19-1398-14

Gentlemen:

In our September 28, 1964 letter, a copy of which is attached, we requested renewal of Martin Marietta byproduct material license No. 19-1398-14. Since a check of AEC records indicates that the letter has not been received by AEC, we have evidently misplaced it here.

Accordingly, we are resubmitting our request for renewal of byproduct license No. 19-1398-14. Procedures which were approved on November 1, 1961 as Amendment No. 8 to byproduct license No. 19-1398-14 and as detailed in subsequently approved amendments number 9, 10 and 11 shall apply.

Thank you for your effort in this matter.

Dear Mr. Johnson:

Martin Company has centralized all Radioactive Materials Management within the Contracts Department. This includes coordination of all licensing activities within the Nuclear Division. The By-product Material Licensing which was previously handled by Mr. Richard J. Brisson, Supervisor of Health Physics, will now be the responsibility of Nuclear Accountability and Licensing Representative, Mr. Charles W. Keller. Mr. Brisson will continue to be responsible for radiological safety at the Martin Company. All correspondence should be addressed as follows:

Form AEC-313
(5-58)

ATOMIC ENERGY COMMISSION

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved.
Budget Bureau No. 38-R027.4.

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail three copies to: U. S. Atomic Energy Commission, Washington 25, D. C. Attention: Isotopes Branch, Division of Licensing and Regulation. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30 and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital, person, etc.)*

Martin Marietta Corporation
Nuclear Division
Baltimore 3, Maryland

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1 (a).)*

Middle River Plant
Middle River, Maryland

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Nuclear Components Department
(Formerly Auxilliary Power Systems Dept.)

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

Renew Byproduct Material License
19-1398-14

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

George Samos

5. RADIATION PROTECTION OFFICER *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Richard H. Boutelle

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*	(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*	
A. Sr^{90}-Y^{90}	A. Any form	100 curies maximum
B. Cesium 137	B. Any	1 curie
C. Americium 241	C. Any	25 millicuries
D. Curium 242	D. Any	20 millicuries
E. Any byproduct material between Atomic Nos. 3 and 83 inclusive	E. Irradiated semiconductors, semiconductor components, and/or mixed fission products	20 curies
F. Promethium 147	F. Any	65 curies
G. Europium 152	G. Any	3 millicuries
H. Europium 154	H. Any	3 millicuries

(See supplemental Sheet No. 1)

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

A. To be used to develop methods of purification and to test corrosion of fuel form compounds.

B. and F. To be used to investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electrical energy.

C, D. and E. To be used to develop methods for separation of Curium 242 from Americium 241 and fission products.

G. and H. To be used in development of chemical processes for purification of rare earths.

I. Transportation of material between facilities of licensee at Middle River, Md. & University of Maryland for the measurement of tracer amounts of radioisotopes in irradiated material.

40627

RECEIVED

TRAINING AND EXPERIENCE OF EACH INDIVIDUAL NAMED IN ITEM 4 *(Use supplemental sheets if necessary)*

8. TYPE OF TRAINING	WHERE TRAINED	DURATION OF TRAINING	ON THE JOB (Circle answer)	FORMAL COURSE (Circle answer)
a. Principles and practices of radiation protection	PREVIOUSLY SUBMITTED IN APPLICATION IN CONNECTION WITH LICENSE NO. 19-1398-14		Yes No	Yes No
b. Radioactivity measurement standardization and monitoring techniques and instruments			Yes No	Yes No
c. Mathematics and calculations basic to the use and measurement of radioactivity			Yes No	Yes No

Gentlemen:

Enclosed are three (3) copies of AEC Form 313 in which we request the renewal of Byproduct Material License No. 19-1398-14. While the program is at the moment the same as it has previously been, certain changes in the facility are contemplated and we expect to apply for additional amendments in the near future.

Should you have any questions regarding this application, please call me at 687-3800 extension 9517.

Yours very truly,

Richard H. Boutelle

Attention: Mr. James R. Mason, Chief
Isotopes Branch

Gentlemen:

It is requested that Byproduct Material License No. 19-1398-14 be amended to permit the possession of twenty-five millicuries (25 mc) of Byproduct Material, Atomic Number 3 - 83 inclusive, in any form, to measure tracer amounts of various radioisotopes in irradiated materials.

It is also requested that this license be amended to permit the transportation of up to twenty-five millicuries (25 mc) of material, Atomic Number 3 - 83 inclusive, under the following conditions:

1. Material will be transported between University Park, Maryland and the Martin Plant at Middle River, in either direction.
2. The packaging and shielding of the licensed materials in transit will be done in accordance with the specifications contained in I. C. C. Regulation, Paragraph 73.393, any exemptions allowed therein notwithstanding.
3. Labeling of materials in transit will be in accordance with specifications contained in I. C. C. Regulations, Paragraph 73.394, exemptions notwithstanding and in conformance with 10 CFR 20.205.
4. The licensed material will be transported in a Martin Company vehicle which will be marked in accordance with I. C. C. Regulations, Paragraph 77.823, in all cases, exemptions notwithstanding.
5. The licensed user will accompany the shipment.
6. Each transfer will be scheduled and will be supervised by the Health Physics Section.

Should any additional information be required, please contact me at 687-3800, extension 9517.

Yours very truly,

Richard H. Boutelle

Attention: Mr. R. L. Lowenstein

Subj: Martin Company Byproduct Licenses

Gentlemen:

Reference is made to The Martin Company's letter of October 10, 1961 requesting your consent to the transfer of the licenses described above from The Martin Company to Martin-Marietta Corporation.

You are advised that the consolidation described in the above referenced letter has been accomplished and your assent to the previously requested transfer is now requested in the name of Martin-Marietta Corporation.

Very truly yours,

W. L. Lucas

U. S. Atomic Energy Commission
Germantown, Maryland

Attention: Mr. R. L. Lowenstein

Subj: Martin Company Byproduct Licenses

Gentlemen:

The Martin Company is in the late stages of concluding arrangements for consolidation with the American-Marietta Company to form a new corporation to be known as Martin-Marietta Corporation. The new corporation will be incorporated under the laws of the State of Maryland and its address will be Box 988, Baltimore 3, Maryland. We are attaching hereto a list of licenses with the location and brief description of each, with the request that you grant authority for transfer of these licenses to the Martin-Marietta Corporation.

The stock of the new company will be listed on the New York Stock Exchange and the predominant ownership and control will be by American citizens.

It is expected that the consolidation will be effective on October 10, shortly after which time you will receive the request from the new corporation to receive the licenses. The existing operations will continue unchanged in the name of the new corporation. The health and safety requirements, the nature of the operations, and the general management of the programs for which the licenses were issued will be in no way effected by the consolidation. I am enclosing herewith, three copies of the Proxy Statement which has been issued to all stockholders which, in effect, confirms this fact. I refer you to pages 20 through 22 for information as to the officers and directors and advise you that they are all citizens of the United States. I also refer you to page 13 and succeeding pages for the proforma combined summary

ATOMIC ENERGY COMMISSION

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved. Budget Bureau No. 38-R027.3.

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail three copies to: U. S. Atomic Energy Commission, Washington 25, D. C. Attention: Isotopes Branch, Division of Licensing and Regulation. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30 and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital, person, etc.)*

The Martin Company
Nuclear Division
Baltimore 3, Maryland

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1 (a).)*

Radioisotope Lab
"D" Building
Middle River, Maryland

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Radioisotope Unit
Nuclear Components Department

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

To Amend 19-1398-14 (RENEWAL)

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

George Samos - Edward Fowler
Arnold Abriss (request application be amended to include this new user at this time)

5. RADIATION PROTECTION OFFICER *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Richard H. Boutelle
(Resume previously submitted)

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*

(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*

A. Sr^{90} - Y^{90}	Any - 100 curies maximum
B. Cs^{137}	Any - 1 curie maximum
C. Am^{241}	Any - 25 millicuries maximum
D. Cm^{242}	Any - 20 millicuries maximum
E. At Nos. 3-83	Any - Mixed - 20 curies maximum
F. Pm^{147} & Daughter	Any - 65 curies maximum

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

A. To develop methods of purification and to test corrosion of fuel form compounds such as strontium titanite.

B. & F. To investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electrical energy.

C. & D. To develop methods for separation of Cm^{242} from Am^{241} and fission products.

The applicant was supervisor of the laboratory in which these experiments were conducted.

29462

Question No. 15 - Waste Disposal

Solid waste is currently stored in 55 gallon steel drums awaiting disposal through an AEC approved, licensed waste disposal service. A record is maintained by Health Physics concerning the contents, radiation and number of each drum.

Liquid waste is monitored to assure that the levels of radioactivity are below the tolerances established in Title 10, Part 20 Code of Federal Regulations for disposal into sanitary sewers. All liquid waste with activity above these levels is evaporated and concentrated for eventual solid waste disposal through AEC approved and licensed waste disposal services.

U. S. Atomic Energy Commission
Division of Licensing and Regulation
Washington 25, D. C.

Attention: Mr. James R. Mason, Chief
Isotopes Branch

Gentlemen:

It is requested that Byproduct Material License No. 19-1398-14 be amended to permit the storage of 350 curies of Am^{241} (oxide, dry) in the shipping containers as received from Oak Ridge National Laboratories. The storage would be in a dry box as previously described in application dated March 11, 1960. The dry box atmosphere will be monitored and any material removed from the dry box will be checked prior to removal. The material stored in this manner would eventually be transferred to the Americium Processing Facility as described in the application submitted for license 19-1398-20.

Should you require any further information please contact the writer or Mr. Richard H. Boutelle, MUrdock 7-3800.

Very truly yours,

THE MARTIN COMPANY

J. V. Loppert
Licensing Officer

Attention: Mr. James R. Mason, Chief
Isotopes Branch

Gentlemen:

It is requested that Byproduct Material License No. 19-1398-14 be amended as shown in the attached Application For Byproduct Material License. In summary the changes requested are:

1. Add George Samos as user.

2. Add the following isotopes to the Strontium 90 previous listed in Part 6: Cesium 137, Americium 241, Curium 242, Promethium 147 and isotopes of Atomic Nos. 3-83 inclusive.

3. Revise authorized use to include programs currently contemplated.

Should any further information be required please contact me at MUrdock 7-3800, X9668 or Mr. Richard H. Boutelle, X9517.

Very truly yours,

Form AEC-313 (5-58)

ATOMIC ENERGY COMMISSION

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved. Budget Bureau No. 38-R027.3.

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail three copies to: U. S. Atomic Energy Commission, Washington 25, D. C. Attention: Isotopes Branch, Division of Licensing and Regulation. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30 and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital, person, etc.)*

The Martin Company
Nuclear Division
Baltimore 3, Maryland

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1 (a).)*

Radioisotope Lab
"D" Building
Middle River, Maryland

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Radioisotope Unit
Nuclear Components Department

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

To Amend 19-1398-14

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

George Samos

5. RADIATION PROTECTION OFFICER *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Richard H. Boutelle
(Resume previously submitted)

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*	(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*
A. Sr^{90}-Yt^{90}	Any - 100 curies maximum.
B. Cs^{137}	Any - 1 curie maximum
C. Am^{241}	Any - 25 millicuries maximum
D. Cu^{242}	Any - 20 millicuries maximum
E. At Nos. 3-83	Any - Mixed - 20 curies maximum
F. Pm^{147} & Daughter	Any - 65 curies maximum

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

A. To develop methods of purification and to test corrosion of fuel form compounds such as strontium titanate.

B. & F. To investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electrical energy.

C. & D. To develop methods for separation of Cu^{242} from Am^{241} and fission products.

(CONTINUED ON SUPPLEMENTAL SHEET NO. 1)

11. METHOD, FREQUENCY, AND STANDARDS USED IN CALIBRATING INSTRUMENTS LISTED ABOVE.

(See SUPPLEMENTAL SHEET NO. 4)

12. FILM BADGES, DOSIMETERS, AND BIO-ASSAY PROCEDURES USED. *(For film badges, specify method of calibrating and processing, or name of supplier.)*

(See SUPPLEMENTAL SHEET No. 5)

INFORMATION TO BE SUBMITTED ON ADDITIONAL SHEETS

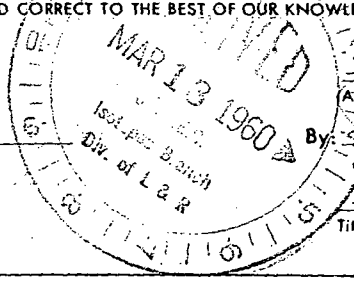
13. FACILITIES AND EQUIPMENT. Describe laboratory facilities and remote handling equipment, storage containers, shielding, fume hoods, etc. Explanatory sketch of facility is attached. (Circle answer) Yes No (See SUPPLEMENTAL SHEET NO. 8)

14. RADIATION PROTECTION PROGRAM. Describe the radiation protection program including control measures. If application covers sealed sources, submit leak testing procedures where applicable, name, training, and experience of person to perform leak tests, and arrangements for performing initial radiation survey, servicing, maintenance and repair of the source.
(See SUPPLEMENTAL SHEET No. 6)

15. WASTE DISPOSAL. If a commercial waste disposal service is employed, specify name of company. Otherwise, submit detailed description of methods which will be used for disposing of radioactive wastes and estimates of the type and amount of activity involved.
(SEE SUPPLEMENTAL SHEET NO. 7)

CERTIFICATE (This item must be completed by applicant)

16. THE APPLICANT AND ANY OFFICIAL EXECUTING THIS CERTIFICATE ON BEHALF OF THE APPLICANT NAMED IN ITEM 1, CERTIFY THAT THIS APPLICATION IS PREPARED IN CONFORMITY WITH TITLE 10, CODE OF FEDERAL REGULATIONS, PART 30, AND THAT ALL INFORMATION CONTAINED HEREIN, INCLUDING ANY SUPPLEMENTS ATTACHED HERETO, IS TRUE AND CORRECT TO THE BEST OF OUR KNOWLEDGE AND BELIEF.



The Martin Company
(Applicant named in item 1)

Date March 11, 1960 By: J. V. Loppert
Licensing Officer
Title of certifying official

WARNING.—18 U. S. C., Section 1001; Act of June 25, 1948; 62 Stat. 749; makes it a criminal offense to make a willfully false statement or representation to any department or agency of the United States as to any matter within its jurisdiction.

Question No. 7 - Describe Purpose for Which Byproduct Material Will Be Used.

E. Includes:

1. Fission products present as impurity in Sr^{90}-Yt^{90} when received.

2. Fission products up to 100 millicuries used to develop methods for separation of Cu-242 from Am-241 and fission products.

3. Irradiated semi-conductors and semi-conductor components. To investigate novel principles for conversion of kinetic energy of corpuscular nuclear radiation to electrical energy.

SUPPLEMENTAL SHEET NO. 1

DUPLICATED
FOR DIV. OF INSP

9. Experience with Radiat A (Actual use of radioisotop or equivalent experience)

	Isotope	Maximum Amount	Where Experience Was Gained	Duration of Experience	Type
A.	C^{14}	Curie Quant.	Brookhaven Nat'l. Lab.	1 yr.	Research
B.	I^{131}		" "	3 yrs.	Research & process dev.
C.	Ce; R.E. Xe, Po	Several Curies	" "	4 yrs. 4 yrs. 2 yrs.	Analysis of solutions from LMFR

EXPERIENCE WITH RADIATION:

Work was done on a small research project to determine maximum concentration of titanium formed in fission. A procedure was developed for decontamination of titanium from other fission products and the investigation was successfully concluded. Several curies of mixed fission products were involved.

A. A one year research program on isotopic exchange between Co_2 of the atmosphere and C^{14} from $BuCO_3$ was also successfully undertaken using tracer quantities.

B. A great deal of work was done with iodine 131 during the development of a device for "milking" I^{131} from Te^{131} for cancer research. This program later changed to Te^{132}. A device was developed and a patent applied for. This device enables a user of short lived I^{132} to have this material constantly available by milking a chromotographic column on which is embedded Te^{132}.

C. With the advent of the LMFR research program at Brookhaven, extensive analytical work was done on corrosion samples from the radiation loop, analyzing for such elements as radioactive iodine, tellurium, cerium, cesium, ruthenium, strontium, rare earths and Xenon. A procedure was developed for the separation of Xenon from metal samples and analysis of its quantity. This work later was extended to samples from reactor irradiated bismuth which contained much polonium. Separation procedures were developed for removing polonium from all samples and also for removing bismuth from samples in which bismuth interferred. Uranium was also separated and analyzed for. Total activity per sample was almost 1 curie.

In addition to the above experience Mr. Samos has conducted the work in the Radioisotope Laboratory of The Martin Company under the direction of Mr. H. O. Banks since January 1959.

SUPPLEMENTAL SHEET NO. 2

Question No. 10 - Radiation Detection Instruments

Type of Instrument	No. Avail.	Radiation Detected	Sensitivity Range	Window Thickness	Use
GM Survey, Nuclear Chicago Md 2612	6	Beta, gamma	0-60,000 c/m 0-20 mr/hr	35 mg/cm^2	Monitoring Surveying
Gas Flow Proportional Counter NMC Md PC-1A	2	Alpha, Beta-gamma	0.5-1,000,000 d/m; 100-1,000,000 d/m	gas chamber	Measuring
Gas Proportional Alpha Counter Eberline Instr. PAC-36	2	Alpha	0-100,000 c/m	0.85 mg/cm^2	Monitoring Surveying
Alpha Scintillation NRD Md-CS-5 + Md S5-A Basic Scintillation Unit	1	Alpha	-	-	Measuring
Alpha, Beta, Gamma Air Particulate Monitor NMC Model AM 33	1	Alpha Beta Gamma	10^{-12} uc/cc Alpha or Beta Gamma	gas prop. detector	Monitoring measuring

Question No. 11 - Method, Frequency, and Standards Used In Calibrating Instruments Listed Above (Question 10)

Calibration of Health Physics survey instruments is performed in the Calibration Facility located in the Waste Storage Room outside the Nuclear Manufacturing and Engineering Laboratories at Plant No. 1. Each instrument is calibrated once a month. Repaired instruments are calibrated when they are returned to Health Physics.

The sources are located in one corner of the Waste Room behind a four foot high, eight-inch thick, cement block wall. A one curie Co-60 source contained in a lead-steel shielded container is used for calibrating "Cutie-Pie" and similar type instruments.

The source is calibrated so that at given distances the dose rate in mr/hr is known. The instrument can be remotely placed at a given distance from the source and calibrated to read the field of radiation at that distance. Where possible, each instrument is calibrated on each scale or range setting.

Smaller Sources include an eight millicurie Co-60 source and a one millicurie Ra-226 source. These are also stored behind the shielding wall and used to calibrate low range (up to 20 mr/hr) instruments.

Neutron survey instruments are calibrated by using a five curie Po-Be neutron source of known flux (determined by foil activation) and setting the instrument to read the correct level.

Counting room instruments are calibrated by using standard calibrated sources of uranium alpha and beta-gamma. The first step is construction of a "plateau" to determine correct operating voltages. The counter efficiency is then determined by comparing the counter countrate with that of the standard source.

The NMC Model AM 33 Alpha-Beta-Gamma Air Particulate Monitor is calibrated by placing a source of known disintegration rate in view of the detector. The source used is the isotope in process at that time. The monitor is calibrated according to the disintegration rate and air flow necessary to match the calibration source.

The Eberline PAC-3G Gas Proportional Alpha Counter is calibrated by placing alpha sources of known disintegration rate in front of the probe face. Check sources and counting plateaus are provided for high voltage adjustments which are necessary with altitude changes.

24901

Question No. 12 - Film Badges, Dosimeters, and Bio-Assay Procedures Used.

A. General:

All personnel working with radioactive materials permanently or temporarily, are required to wear a film badge and two pocket chambers sensitive to beta-gamma radiation.

Personnel working in areas where fast and/or thermal neutron radiation is prevalent are required to wear a film badge sensitive to beta, gamma and fast neutrons and pocket chambers sensitive to thermal neutrons.

Film badges are changed either weekly, biweekly, or each 13 weeks depending upon the radiation levels in the work areas. Pocket chambers are changed and read daily. Self-reading dosimeters are also available and used under the discretion of Health Physics.

A film badge service is contracted on a yearly basis to supply and process film and badges for the program. The present supplier is Health Physics Services, Baltimore, Maryland

B. Dosimetry Information:

Special film badge changes are made by Health Physics when any of the following conditions exist:

(1) Both pocket chambers off scale.

(2) Exposure in excess of 100 mr/wk is recorded from daily pocket chamber readings.

(3) Inexplicable exposure in excess of 50 mr per day is recorded.

Permanent records are maintained of all film badge and pocket chamber results.

The upper limit of dosimetry response is as follows:

FILM BADGES	UPPER LIMIT (rem)
Gamma	1000
Beta	500
Neutrons	100
POCKET CHAMBERS	
Gamma	200 mr
Neutrons	200 mrem

24901

(Question No. 12 - Cont'd.)

C. Bioassay

All facility personnel are required to submit bioassay samples at periodic intervals. In the case of unusual incidents, including exposure to airborne concentrations of radioactive materials exceeding the maximum permissible concentrations for personnel without respiratory protection, or other suspected ingestion of radioactive material, special samples are collected from all personnel involved.

All urinalysis results are filed as permanent records in the Health Physics office and are available to responsible persons upon request.

24801

Question No. 14 - Radiation Protection Program

A. Health Physics Responsibilities:

1. Plans and administers the radiation protection program to provide adequate protection to Company and to personnel from ionizing radiation.

2. The inspection and monitoring, with the aid of various detection instruments, of personnel, machinery, furniture, ventilating equipment, gamma and neutron irradiation test facilities, radioisotopic laboratories, etc., to detect and prevent spread of radioactivity, measure levels of radiation or concentrations of radioactive materials present.

3. The review and approval of all working areas and facilities.

4. The evaluation of radiation hazard control methods for adequacy and compliance with recommendations of the National Committee on Radiation Hazards and pertinent government regulations.

5. The promotion of the Health Physics program through the proper indoctrination and training of personnel engaged in handling or working with materials or equipment that emit ionizing radiation.

6. Determines radiation monitoring equipment requirements in all areas.

7. The internal control and enforcement of licensing regulations pertaining to receiving, possession, use, transfer and disposal of nuclear source, special nuclear, or by-product materials.

8. The investigation of accidents and personnel radiation exposures to determine the cause and recommend corrective action to be taken to eliminate future occurrences.

9. The continual monitoring of personnel engaged in handling or working with radioactive materials and x-ray equipment for compliance with recommended procedures and regulations of good housekeeping and work habits.

10. The issuance of appropriate personnel monitoring devices (film badges, pocket chambers, etc.), scheduling of pre-exposure and follow-up physical examination, and the establishment and maintenance of detailed employee records of cumulative doses of radiation exposure, biological assays, laboratory reports, etc., to form the basis of permanent Company records and to conform to Atomic Energy Commission regulations.

11. The conducting of laboratory tests of environmental sample analyses and biological assays to determine the quantity of radioactivity discharged to the environs and the quantity received by the individual through inhalation, ingestion, wounds, etc.

Question 14 - Cont'd.

12. Collaborates with representatives of the various divisions and departments concerned on reactor site surveys, design of facilities, power reactors and associated control systems for hazard evaluation and control to assure protection of personnel and facilities.

13. Maintains liaison with representatives of the Atomic Energy Commission, National Committee on Radiation Hazards, Federal, State and Local government health and welfare agencies, and various divisions and departments, to resolve areas of common health physics interest.

14. Prepares and revises as necessary Health Physics bulletins outlining procedures to be followed to assure compliance with all pertinent National Committee or radiation hazards recommendations and government regulations.

15. The calibration of all Health Physics monitoring instruments where radiation sources must be used to perform the calibration.

B. Leak Testing

Leak tests are performed on all sealed sources when they are received and at least once every three months thereafter. The source, or source shield, depending upon the strength of the source, is wiped with a filter paper disc. The disc is then counted in the proper radiation counter to detect and measure any leakage of alpha or beta-gamma contamination.

Radium sources are leak tested by wrapping the source in cotton for approximately three days, removing the cotton and counting it with a beta-gamma detector.

Leak tests are performed by Health Physics technicians who have had three years of on-the-job Health Physics training with The Martin Company.

Maintenance, service and repairs to all sources are performed by the source supplier.

C. See also supplementary report MND 2109.

24301

Question No. 15 - Waste Disposal

Solid waste is currently stored in 55 gallon steel drums awaiting disposal through an AEC approved, licensed waste disposal service. A record is maintained by Health Physics concerning the contents, radiation and number of each drum.

Liquid waste is monitored to assure that the levels of radioactivity are below the tolerances established in Title 10, Part 20 Code of Federal Regulations for disposal into sanitary sewers. All liquid waste with activity above those levels is evaporated and concentrated for eventual solid waste disposal through AEC approved and licensed waste disposal services.

24901

Question No. 13 - Facilities and Equipment

The Radioisotopes Laboratory consists of 3 sections - a small office area, a general lab for doing cold chemistry and tracer level chemistry, and a large room 22 ft. square which is being set up as a warm chemistry lab.

The general lab has a main lab bench, several tables, counting equipment and a hood. The air flow through the hood, with the door half way down is 100 l.f.m. An absolute type filter is in the line to absorb all particulate matter. The interior of the hood is of stainless steel, top, sides and bottom. Work involving use of trace quantities of isotopes is done in the hood. The floor of the hood is covered with "kimpak", an absorbent paper, and this is covered with polyethylene sheeting to facilitate decontamination, if a spill should occur. Liquid radioactive waste is kept in a 5 gallon polyethylene bottle. Metal pails with polyethylene bag liners are used for solid waste. A bench monitor is used to survey glassware, hands and clothing for $\beta\gamma$ contamination. Portable gas flow proportional counters will be used for α monitoring.

The large area, a room approximately 22' X 22' is currently being prepared for alpha chemistry work. The room has 2 foot thick concrete walls. A fiber glass polyester resin floor has been laid over the existing concrete floor to facilitate decontamination should a spill occur. A 6" thick steel door, on rollers, is located in the outside wall of the room to enable large pieces of equipment to be brought into the room. This room has been used for gamma radiography and the heavy steel door served as a radiation shield. The doorway will be altered so that two regular doors can be installed. The steel door will then be left normally open unless the radiation level will be such as to make closing necessary.

Americium, curium and plutonium chemistry will be done in glove type dry boxes. Each box is 27" deep, 26" long and 30" high with sloping safety glass fronts incorporating 8" fiberglass gloves. The box will be made of plastic sandwich honeycomb with coved corners, 1/8" thick stainless steel floor, and safety plate glass mounted in interlock rubber retainer. Filters are two replaceable Pf 105 inlet and one combination pre-filter Cambridge absolute type filter rated for 50 cfm, at 1" $H_{2}O$. A fluorescent light fixture and four liquid line fittings are also provided. All plastic materials are fire and chemical resistant. The box has 7" X 8" access ports at each end of the box which open inward and lock shut against neoprene gaskets to seal the chamber.

DUPLICATED

Amend. 19-1398-10

Form AEC-313 (5-58)	ATOMIC ENERGY COMMISSION **APPLICATION FOR BYPRODUCT MATERIAL LICENSE**	Form approved. Budget Bureau No. 38-R027.3.

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail three copies to: U. S. Atomic Energy Commission, Washington 25, D. C. Attention: Isotopes Branch, Division of Licensing and Regulation. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30 and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

CANCELLED FOR DIV. OF NMSP

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital, person, etc.)*

The Martin Company
Baltimore 3, Maryland

Attn: Mr. R. G. Macaulay
Licensing Officer

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1 (a).)*

Martin Plant
Middle River, Maryland

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Isotopic Power Development Dept.
of Nuclear Division

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

Eight Byproduct Material Licenses are currently in effect.

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

Hampden O. Banks, Jr.
Assistant Project Engineer

5. RADIATION PROTECTION OFFICER *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Paul R. Guinn - See Resume Submitted With Martin Application Dated Dec. 13, 1957-
Re: License No. 19-1398-9
Amendment No. 2

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*

Strontium-90

(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*

A maximum of 100 curies of strontium-90 to be procured in the oxide or nitrate form.

Note: It is anticipated that 10 curies will be procured immediately upon the issuance of the Byproduct Material License, the balance from time to time during the progress of the work identified below.

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

1. For experimental work under Contract AT(30-1)-2281 between Martin and the AEC, to determine methods of purifying strontium-90.

2. To investigate the applicability of strontium-90 for use in the development of battery heaters, transmission oil heaters, and other military low-level applications.

TYPE OF INSTRUMENTS *(Include make and model number of each)*	NUMBER AVAILABLE	RADIATION DETECTED	SENSITIVITY RANGE *(mr/hr)*	WINDOW THICKNESS *(mg/cm²)*	USE *(Monitoring, surveying, measuring)*
See list submitted with License Application dated September 22, 1958.					

11. METHOD, FREQUENCY, AND STANDARDS USED IN CALIBRATING INSTRUMENTS LISTED ABOVE.
See statement submitted with License Application dated September 22, 1958.

12. FILM BADGES, DOSIMETERS, AND BIO-ASSAY PROCEDURES USED. *(For film badges, specify method of calibrating and processing, or name of supplier.)*
See statement submitted with License Application dated September 22, 1958.

INFORMATION TO BE SUBMITTED ON ADDITIONAL SHEETS

13. FACILITIES AND EQUIPMENT. Describe laboratory facilities and remote handling equipment, storage containers, shielding, fume hoods, etc. Explanatory sketch of facility is attached. *(Circle answer)* Yes, No See statement submitted with Application dtd. Sept. 30, '58

14. RADIATION PROTECTION PROGRAM. Describe the radiation protection program including control measures. If application covers sealed sources, submit leak testing procedures where applicable, name, training, and experience of person to perform leak tests, and arrangements for performing initial radiation survey, servicing, maintenance and repair of the source. See statement submitted with License Application dtd. Sept. 22, 1958

15. WASTE DISPOSAL. If a commercial waste disposal service is employed, specify name of company. Otherwise, submit detailed description of methods which will be used for disposing of radioactive wastes and estimates of the type and amount of activity involved. See Application dtd. Sept. 22, 1958

CERTIFICATE (This item must be completed by applicant)

16. THE APPLICANT AND ANY OFFICIAL EXECUTING THIS CERTIFICATE ON BEHALF OF THE APPLICANT NAMED IN ITEM 1, CERTIFY THAT THIS APPLICATION IS PREPARED IN CONFORMITY WITH TITLE 10, CODE OF FEDERAL REGULATIONS, PART 30, AND THAT ALL INFORMATION CONTAINED HEREIN, INCLUDING ANY SUPPLEMENTS ATTACHED HERETO, IS TRUE AND CORRECT TO THE BEST OF OUR KNOWLEDGE AND BELIEF.

Mr. William O. Miller
Senior Licensing Reviewer
U. S. Atomic Energy Commission
Isotopes Branch
Division of Licensing & Regulation
Washington 25, D. C.

Dear Mr. Miller:

It is requested that a Byproduct Material License authorizing The Martin Company to transfer, receive, acquire, own and possess 100 curies of strontium-90 be issued in accordance with the provisions of Part 30 of Title 10 of the Code of Federal Regulations.

In support of this request, I am enclosing herewith three duly completed copies of AEC Form-313. I might point out that, except for the quantity of strontium-90 required and the purposes for which it will be used, the enclosed Application is identical to our Application dated September 30, 1958, which resulted in the issuance of Byproduct Material License No. 19-1398-14. Consequently, it may be convenient for you to issue an amendment to the existing license rather than to issue a new license.

Please give me a call (MUrdock 7-3800, extension 595, collect) if you desire clarification or any additional information relative to the enclosed Application.

Very truly yours,

THE MARTIN COMPANY

19-1398-14

THE MARTIN COMPANY

Baltimore 3, Maryland

November 10, 1958

3226

DUPLICATE
FOR DIV. C...

Mr. Raymond Herbin
Isotopic Branch
Division of Licensing Regulation
U. S. Atomic Energy Commission
1717 H Street, N. W.
Washington 25, D. C.

Dear Mr. Herbin:

I wish to acknowledge receipt of Byproduct Materials License No. 19-1398-14 covering 100 millicuries of Strontium-90 and thank you for your cooperation and assistance in expediting its issuance.

Reviewing the license, I note that Item 9 defines the authorized use as follows: Corrosion, stability, and similar laboratory studies to determine the integrity of cements (containing Strontium-90) as a source of heat and power. I believe that the reference to "cements" in the foregoing definition should be to "cermets." I assume that this is simply a typographical error and that it will be unnecessary to issue a correcting amendment, but please let me know if such is not the case.

Very truly yours,

THE MARTIN COMPANY

Enclosure

ENCLOSURE

LABORATORY CONTAINMENT PROCEDURE FOR STRONTIUM-90

All chemical processing, furnace cermeting, sintering, cladding and corrosion testing of the Strontium-90 contained material will be conducted in a Kewaunee Model 3604 type fume hood. This hood is equipped with an absolute filter and will be maintained at a slight negative pressure. The front portal will be modified by installing a pressure gasketed lucite panel. Hand access into the hood will be accomplished by means of obstetrical type rubber gloves securely attached to the lucite panel. Transfer of material will be made through a double airlock type of exit; an eleven (11) such transfers will be supervised by the Health Physics Department. Air sampling will be maintained throughout the study both in the hood room and at the filtered air exit to the outside. In addition, face masks, surgical gloves, smocks and shoe covers will be used as needed. Entrance into and exiting from the hood room by authorized personnel will be monitored by a Health Physicist. Adequate containment of all waste materials both liquid and solid will be maintained. An estimated 1 to 2 mc of Strontium-90 will be contained in each finished cermet. No unclad cermets will be removed from the hood.

Dear Mr. Herbin:

Per our telephone conversation of October 30th, I am attaching the information on the Fume Hood equipment together with the amounts of Strontium-90 per cermet to be used by Martin-Nuclear on our Strontium Heat Source Program.

I trust that this data is adequate and will appreciate any effort on your part to expedite the licensing procedure necessary for my procurement of 100 mc of Strontium-90. If any further information is required, please do not hesitate to contact me.

Very truly yours,

Form AEC-313 (2-57)

...OMIC ENERGY COMMISSION

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved. Budget Bureau No. 38-R027.3.

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail two copies to: U. S. Atomic Energy Commission, P. O. Box E, Oak Ridge, Tenn. Attention: Isotopes Extension, Division of Civilian Application. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30 and the licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital, person, etc.)*

The Martin Company
Baltimore 3, Maryland

Attn: Mr. R. G. Macaulay
Licensing Officer

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1 (a).)*

Martin Plant
Middle River, Maryland

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Isotopic Power Development Dept.
of Nuclear Division

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

Seven Byproduct Material Licenses
are currently in effect.

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

Hampden C. Banks, Jr.
Assistant Project Engineer

5. RADIATION PROTECTION OFFICER *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Paul R. Guinn - See Resume Submitted With Martin Application Dated Dec. 13, 1957 - Re: License No. 19-1398-9, Amendment No.2

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*

Strontium-90

(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*

100 millicuries of Sr. 90 to be received in the oxide form.

DUPLICATED
FOR DIV. OF INSP.

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

Phase I - The above byproduct material will be used in the performance of corrosion and stability studies of Sr. containing cermets, such studies being designed to determine the integrity of the cermet as a source of heat and power. Trace amounts of radio Sr. will be mixed with stable Sr.

Phase II - A similar cermet containing trace amounts of radio Sr. will be placed in a double container. Corrosion tests will then be performed to determine the integrity of this system.

13369

(Continued on reverse side)

TRAINING AND EXPERIENCE OF EACH INDIVIDUAL NAMED IN ITEM 4 *(Use supplemental sheets if necessary)*

8. TYPE OF TRAINING	WHERE TRAINED	DURATION OF TRAINING	ON THE JOB (Circle answer)	FORMAL COURSE (Circle answer)

THE MARTIN COMPANY

Baltimore 3, Maryland

September 30, 1958

Mr. James W. Hitch
U. S. Atomic Energy Commission
Isotopes Branch
Division of Licensing and Regulation
Washington 25, D. C.

Dear Mr. Hitch:

It is requested that a Byproduct Material License authorizing The Martin Company to transfer, receive, acquire, own and possess 100 millicuries of strontium-90, be issued in accordance with the provisions of Part 30 of Title 10 of the Code of Federal Regulations. In support of this request, we have completed and I am enclosing herewith three copies of AEC Form-313.

All of the work described in Item 7 of the Application will be performed pursuant to a contract currently being negotiated with the Atomic Energy Commission. Since we are anxious to commence this work at an early date, I shall appreciate it if you will give me a call (MUrdock 7-3800, Ext. 595 or 596) in the event that you desire any further information relative to the enclosed Application. I might add that Dr. Paul Abersold of the AEC is familiar with the technical aspects of the work.

Very truly yours,

THE MARTIN COMPANY

THE MARTIN COMPANY

Baltimore 3, Maryland

December 12, 1957

Director
U. S. Atomic Energy Commission
Division of Civilian Application
Washington 25, D. C.

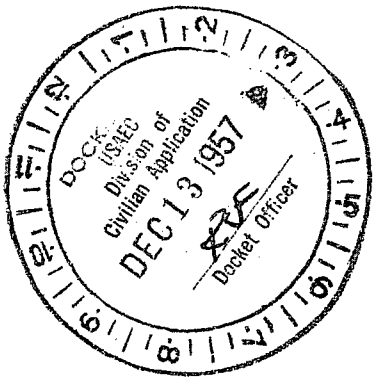
Attention Mr. Lyall Johnson
Chief, Licensing Branch

Dear Mr. Johnson:

Enclosed are three (3) signed and notarized copies of an application for a general license to receive, possess, use and transfer special nuclear material pursuant to Part 70, Title 10, Code of Federal Regulations. Appendix A to the application, a revision of MND-1063 filed April 22, 1957, is under preparation and will be submitted as soon as possible. Appendix F, MND-1069, is business confidential and therefore is supplied in two copies under separate cover.

The Martin Company holds License No. SNM-11, as amended June 12, 1957, authorizing the use of a maximum of two kilograms of U235 in special nuclear materials for fuel element research and development to be performed principally in the Nuclear Division Engineering Materials Laboratory. The enclosed application requests authorization for use of a maximum of five hundred kilograms of contained U235 in all facilities at Middle River including the Critical Experiment Facility. In this connection, reference is made to License No. SNM-53 as amended May 3, 1957 which permits the storage of fifty kilograms of UO_2 containing uranium enriched in the isotope U235.

Request is made also at this time for an allocation for calendar year 1958 of one hundred and fifty kilograms of U235 contained in special nuclear materials enriched up to over 90% in the isotope U235. This general allocation is requested as it is not possible to anticipate all of the various forms and enrichments which will be required for commercial work.



Very truly yours,

THE MARTIN COMPANY

APPLICATION FOR GENERAL LICENSE TO RECEIVE, POSSESS, USE AND TRANSFER SPECIAL NUCLEAR MATERIAL (PART 70, CFR 10)

I. The Martin Company is engaged in design, research, development and construction of nuclear reactors and nuclear components at its Middle River Plant near Baltimore, Maryland. For the purpose of development and fabrication of reactor fuel elements, a Nuclear Materials Laboratory and a Pilot Manufacturing Plant have been constructed in the basement of "D" Building at Plant I. A critical experiment facility for zero power testing of proto-type reactor cores is in the final stage of completion. This facility is located near the Martin airport some two thousand feet southeast of Plant I.

Research and development work on fuel elements is conducted under Special Nuclear Material License No. 11, as amended, in accordance with procedures described in the Company's applications of May 22, 1957 and September 19, 1957. The most recent revision of this license permits special operations involving fully clad fuel elements to be performed in the pilot manufacturing plant and in other buildings at Plant I in addition to the laboratory areas.

Initial operation of the Pilot Manufacturing Plant involves fabrication of stainless steel tubular elements containing highly enriched UO_2, for a proto-type MPR core to be tested to zero power for the Atomic Energy Commission under Contract AT (30-3)-277. Government-owned fuel has been handled through Accountability Station MND, which was authorized by the Schenectady Operations Office after approval of the Martin Nuclear Division's procedures regarding criticality control, accountability, health and safety, and security.

In addition to MPR type tubular elements, The Martin Company plans to fabricate other fuel element types in the Pilot Manufacturing Plant. Certain special operations will be performed in other buildings at Plant I. Some of the work to be undertaken will be on a commercial basis and therefore must be done under a Special Nuclear Material License issued by the Commission. In this connection, note is made that the Commission issued SNM License 53 to The Martin Company on November 26, 1956 permitting receipt and possession of fifty (50) kilograms of UO_2 enriched to over 90% in the isotope U235.

Several types of fuel elements including rods, tubes and plates will be manufactured. These elements will utilize uranium metal or uranium dioxide in a fuel marrow clad with such materials as stainless steel, aluminum alloys and zirconium alloys.

In view of these varied contemplated activities, The Martin Company pursuant to Part 70, CFR 10 hereby applies for a general license to receive, possess and use up to five hundred kilograms of contained U235 in special nuclear materials at its Middle River facilities, including uses in the Critical Experiment Facility other than activities licensed under Part 50, CFR 10. Application is made for a license extending for three years from date of issuance. The experience gained by the Nuclear Division during the past three years in safe handling of nuclear materials is reflected in the general procedures outlined in this application in sections which follow.

II. Information required pursuant to Section 70.22, Title 10, Chapter 1, CFR:

(1) Applicant is The Martin Company, Baltimore 3, Maryland incorporated in the State of Maryland and having its principal plant and place of business at Middle River, Maryland.

Principal officers are:

G. M. Bunker, President, The Martin Company, Baltimore 3, Maryland - USA

W. B. Bergen, Executive Vice President, The Martin Company, Baltimore 3, Maryland - USA

W. L. Lucas, Secretary and Treasurer, The Martin Company, Baltimore 3, Maryland - USA

The Martin Company is not owned, controlled, or dominated by an alien, a foreign corporation, or foreign government. The applicant is the real party in interest and is not making this application as an agent for any undisclosed principal.

(2) Activities:

Attached for reference are plans of the nuclear facilities at the Martin Middle River plant showing work areas and quantities of special nuclear material (in terms of contained isotope U235) permitted in each work area:

Plate 1 - Plan of Engineering Materials Laboratory
Plate 2 - Plan of Pilot Manufacturing Plant
Plate 3 - Plan of Critical Experiment Facility located near Martin airport.

General procedures in connection with activities contemplated are:

(a) Receiving -

SNM will be received at Gate 5 of Plant I by the Accountability Representative. After monitoring by Health Physics Services for radiation hazards, shipments will be conveyed to Vault Annex Room, (Work Area IB) or Vault, (Work Area IA) for unpacking and weighing of special nuclear material.

(b) Storage -

The storage vault is a fully enclosed room, 22'8" by 13'9" by 11'0" high. It is designed to hold up to 600 kilograms of enriched uranium in powders, foils, elements or ingots stored in birdcage devices approximately 12" x 12" to 17" x 17" in cross-section. Walls, ceiling, and floor are constructed of a minimum of 9 inches of reinforced concrete. Sole entrance to the vault is through a $1\frac{1}{2}$" steel door equipped with a three-way combination lock. There are no water or service piping or drains within the vault.

Materials will be stored in separate containers containing quantities which are less than the theoretical critical masses calculated for optimum conditions with respect to geometry of container, moderators, and reflector according to the calculating procedures outlined in the Martin Criticality Precautions Manual, MND-1063 (Appendix A) and its reference "A Guide to the Calculation of Criticality Limits for Enriched Uranium" by Dr. Chernick. Each container will be at least 12" x 12" in cross-section with a length about 12" longer than the material to be held. Containers and birdcages will vary in design according to the form of the material. For example:

Uranium dioxide powders will be stored in metal bottles of approximately 150 cubic centimeters capacity. No more than 600 grams of uranium dioxide enriched to over 90% in the isotope U235 or more than 550 grams of contained isotope U235 will be stored in each metal bottle. One and only one bottle will be suspended inside a cubical "birdcage" type structure of welded metal construction having dimensions of 16 5/8" x 16 5/8" x 21 3/8".

Uranium metal foil will be stored in birdcages 12" x 12" x 34" with bundles of foil each containing no more than 1000 grams of U235 held roughly in the center by inserts.

Fuel elements, tubular or plate, will be held in cradles in storage devices or similar dimensions (12" x 12" x 30-40"). Each cradle will hold a prescribed number of tubes or plates, the total U235 content of which will be within the allowable limits established for the particular form of material involved.

Solid scrap will be stored in metal boxes 9 1/2" x 11 3/4" x 26", each held in a birdcage 12" by 12" x 40" long.

Insofar as it is practical, all birdcages will be placed in rows along the walls of the vault to permit easy access. The lowest rows will be placed on platforms about 17 inches above the floor to prevent accidental contact with water. Even if flooding occurred above the height of 22" required to reach any special nuclear material, no hazard would exist since (1) all materials will be in latched birdcages in amounts less than the theoretical critical limits and (2) powders will be in water-tight metallic containers within the birdcages.

All material will be stored during non-work hours either in the vault or in locked repository safes in the manufacturing area.

When special nuclear material must be taken from the nuclear facilities to other areas within the Martin plant, it will always be in the custody of a "Q" cleared accountability designee.

(c) Forms of material -

Forms with corresponding allowable limits in contained U235 have been established as shown on the following two pages.

(d) Work Areas and Criticality Control -

Reference is made to Plates 1, 2 and 3 and to the Martin Criticality Precautions Manual, MND-1063, filed with the AEC, April 22, 1957. A revised copy of this manual is attached as Appendix A. The manufacturing area and the critical experiment area have been divided into Work Areas for purposes of control of criticality. The laboratory except for a few designated work areas is considered to be one integral work area. Limits (in terms of U235) are shown on the plates for the various

FORM	ENRICHMENT OF URANIUM IN ISOTOPE U235	TYPE OF MATERIAL	ALLOWABLE LIMIT IN ANY WORK AREA (grams of contained U235)

VIIa	all enrichments	UO_2 and powdered Al mixture, approx. density 2.5 gr/cc	800 grams
VIIb	all enrichments	Pressed or sintered UO_2 and Al mixture in (VIIa) approx. density 5.0 gr/cc	800 grams

FORM	ENRICHMENT OF URANIUM IN ISOTOPE U235	TYPE OF MATERIAL	ALLOWABLE LIMIT IN ANY WORK AREA (grams of contained U235)
VIIIa	all enrichments	Aluminum alloy clad tubes with Form VIIb as fuel marrow	800 grams
VIIIb	all enrichments	Iron-aluminum alloy clad tubes with Form VIIb as fuel marrow	800 grams
IX	over 20.0%	Uranium metal in buttons, derbies, etc.	10000 grams (2)
X	over 20.0%	Uranium metal in ingots, bars, machined shapes, smallest dimension 70.25 inches	3000 grams
XI	0.72% to 20.0%	Stainless steel clads filled with solid pellets of Form Ib or Ic	2000 grams
XII	over 20.0%	Zirconium, titanium, molybdenum and other "special" alloy-clad plates with uranium metal fuel marrow	grams (3)
XIII	over 20.0%	Uranium-thorium molybdenum alloys	grams (3)

(1) Except when total amount in any one container in all forms is less than 400 grams of U235

(2) Subject to review with regard to minimum dimensions and reflecters

(3) To be determined

forms of SNM (pages 5 and 6) which can be present in each work area at any one time. In the event that several forms are present at one time in a work area, the lowest allowable limit for U235 applies to all materials present.

All transfers between work areas are made by the courier acting as a designee of the Accountability Representative. Enforcement of criticality procedures within work areas is a responsibility of each facility supervisor. Material, under close weighing control, is transported to an "Off-Spot" in work boxes in "carrier" devices. Amounts present in each work area are shown on prominent signs posted by the Accountability Representative.

(e) Manufacturing -

Fabrication of fuel elements will be performed in the pilot shop located in "D" Building.

A few special operations such as brazing of fully clad tubes to end castings will be done in other buildings at Plant I.

Processes, either developed or being developed include:

(1) Fabrication of stainless steel clad plates enclosing uranium metal foil (Form I)

(2) Stainless steel clad tubes enclosing fuel marrow of enriched uranium dioxide-stainless steel cermet (Form IV)

(3) Aluminum and aluminum alloy clad tubes enclosing pressed uranium dioxide-aluminum blended compacts as fuel marrow (Form VIII)

(4) Stainless steel clads filled with solid compacts of uranium dioxide or uranium dioxide and thoria (Form XI)

General descriptions of these processes are outlined in Appendix B with corresponding manufacturing flow charts shown in Appendix C.

(f) Accountability -

The Martin Nuclear Division accountability procedures for strict control of valuable special nuclear materials

apply to both government-furnished SNM and to licensed SNM. Each lot received is assigned a ledger number. All material withdrawn is kept separate from other lots throughout processing. Scrap is kept segregated by contract or project. Thus there is no risk of intermingling materials or several contracts or of different enrichments.

(g) Security -

All facilities are controlled areas with only authorized personnel permitted access. An escort-control pass system is applied to authorized visitors.

Materials are given security protection in accord with the categories outlined in the AEC manual.

(h) Transport to Critical Experiment Facility -

Finished fuel tubes, plates or rods are moved to the facility in "birdcage" transporting devices in a guard-escorted motor vehicle. No more than 800 grams of U235 contained in sealed elements are allowed per "birdcage" device. These birdcage devices are 12" by 12" by 34" and retain in a center position wooden cradles 9 1/2" by 11 3/4" by 23 3/4" which hold the fuel tubes or plates.

(i) Receipt and Storage at Critical Experiment Facility -

After verification by the Accountability Designee of the Facility of the number of tubes or plates delivered the birdcages will be placed in the storage vault. The vault is of similar construction to the vault in the pilot manufacturing plant and has a floor area of 175 square feet. It is accessible only through a 1 1/2" steel door equipped with a three-way combination lock.

(j) Assembly at Critical Experiment Facility -

Tubes or plates are assembled into experimental bundles in Work Area 102, adjacent to the Storage Vault and Test Cells.

Following assembly, the fuel elements (bundles or boxes) will be placed in wooden cradles which are held in the birdcage storage devices. The dimensions of the cradle holding a bundle of thirty-seven (37) MPR tubes are 9 1/2" by 11 3/4" by 23 3/4".

The birdcage devices are then transferred to the storage vault for retention until withdrawal for experimental work authorized by a Class 104 c license.

(k) Shipping procedures -

Shipments of special nuclear material to the Commission or to other licensees will be made as follows:

(1) If the shipment contains no more than 100 grams of U235, the material will be securely packed in a container with resilient material between this container and the outside package. In addition, the parcel will be checked for possible radiation hazards and marked in accordance with ICC regulations.

No more than one package containing up to 100 grams of contained U235 will be transported or delivered to a carrier in any one shipment.

(2) If the shipment contains over 100 grams of U235, the material, depending on its form, will be packed in a container in either one of the Martin "birdcage" devices described in part 2(b) or an equivalent device to be furnished by the shipper. The quantity of U235 in any shipping device will be within the allowable limits for various forms shown on pages 7 and 8 of the manual, MND-1063.

(3) A general license is requested for a period of three years.

(4) Special Nuclear Material will be used in the forms shown in section 2(c). The general categories are:

Uranium dioxide powder; low-enrichment to over 90% enriched in isotope U235
Uranium metal foil, ribbon and wire; low-enrichment to over 90% enriched in isotope U235
Uranium metal ingots, slugs, billets, bars, derbies; all enrichments.

It is not possible to estimate amounts of each type required. However, a total requirement at one time of up to 500 kilograms of contained U235 in SNM is foreseen.

(5) The contemplated requirements for Special Nuclear Material for the last quarter of 1957 and the first quarter of 1958 are shown on the next page.

(6) The Martin Nuclear Division has been engaged in handling special nuclear materials for over two years in research and development of fuel elements. The new laboratory and pilot manufacturing plant have been in operation since June, 1957.

Several new concepts of fuel elements have been developed including the highly-enriched stainless steel clad, UO_2 cermet marrow tubular type. The first core loading of 1700 of these tubes will be completed in November. The technical staff of the Nuclear Division includes some 200 engineers. The manufacturing plant supervisor has had fifteen years of precision shop experience. Health Physics personnel include two senior health physicists each with over 5 years of training at AEC and industrial installations. The Accountability Representative is a public accountant with 10 years experience including 9 months in the handling of nuclear materials.

(7) Equipment and facilities used to protect health and safety -

Storage facilities are described in (2b) and (2i). The manufacturing and laboratory areas are under negative pressure with respect to adjacent working areas of "D" Building. Air flow is from non-contaminated areas to slightly-contaminated areas to more-contaminated areas, with the highest ventilation rates in those rooms or areas where the greatest air-borne contamination is possible.

Exhaust air that may contain appreciable radioactive particulate matter (that is from the hoods or dry boxes) is passed through absolute filters before being released to the atmosphere.

Hoods are used for handling uranium dioxide powders. These hoods, exhausting ducts and glove boxes are equipped with absolute filters. Machining of uranium metal will be done using an oil bath.

A partial list of available instruments and equipment appears as Appendix D.

MATERIAL	ENRICHMENT	QUANTITY ON HAND	4TH QUARTER 1957		1ST QUARTER 1958	
			Receipts	Returns	Receipts	Returns
UO_2 Powder	20%	5 kg	-	3	-	2
UO_2 Powder	over 90%	50 kg	20	25	10	25
Uranium foil	over 90%	0.5 kg	-	-	-	-
Uranium foil	over 90%	-	31	-	-	-
Uranium metal ingot	31%	-			40	40
Uranium metal ingot	over 90%	-			100	100

(8) Health and Safety measures -

Personnel working with radioactive materials (including SNM) or in radiation areas are routinely monitored for external radiation exposure by means of film badges and pocket chambers. Contamination is controlled by surveying likely objects or areas with appropriate detecting instruments or by making filter paper smears (which must be counted with an appropriate detector), recording results, and informing proper supervision. All operating personnel must be constantly alert to contamination possibilities involved in their operations and must continually strive to keep contamination to a minimum. Health Physics takes air samples in areas where airborne contamination is possible (frequency of sampling depends on operation). A tolerance of no more than 5×10^{-11} microcuries per milliliter air is established. If this tolerance is approached all personnel in the area affected are required to wear respirators. Uranium urinalyses and blood tests will be made every three months to check on internal deposition on people assigned to work in these areas.

From receipt of material to shipping or storage, Health Physics will be concerned with contamination and radiation levels from the SNM. External radiation measurements will be made on the received package and recorded. The Accountability Representative will open these packages. Health Physics shall assist in examination for breakage or other damage and subsequent contamination control in case of damage. During weighings of received SNM, Health Physics will make necessary smear checks. Samples to be sent for outside laboratory analysis will be packaged to conform with all pertinent ICC regulations.

Contamination control effectiveness will be checked by Health Physics throughout the operations in the laboratory and in the pilot manufacturing plant.

Protective clothing will be used to reduce personnel contamination.

Disposal of radioactive wastes: There will be no radioactive gaseous effluent from the Martin facilities. The incineration of radioactive combustible materials will be controlled by monitoring the exhaust stack of the incinerator.

Liquid wastes will be stored in polyethelene lined 55 gallon drums until ready for concentration. Batches containing no more than 400 grams of U235 will be reduced nearly to dry salt and these residues will be sent to AEC installations for recovery.

Solid wastes such as incinerator ashes will be mixed with a prepared cement mix before disposal by land or sea burials in accordance with Part 20, CFR 10.

The large volumes of slightly contaminated liquid wastes from the Decontamination Laundry will be held in collecting sumps until filtered, sampled, and counted for radioactivity before discharge to the sanitary sewer. Tap water dilution will be used, if necessary, to reduce the concentration to the levels required by 10 CFR Part 20.

(9) Emergency procedures -

An outline of the procedures to be followed in case of incidents involving nuclear materials is contained in the Criticality Precautions Manual, MND-1063, pages 5 and 5a.

(10) Financial Qualifications -

The Martin Company has done business under its present charter in the State of Maryland for a period of over twenty-five years. (b)(4) (b)(4) (b)(4) The Nuclear Division, headed by a General Manager, is part of the company organization and draws its budgetary support therefrom. Ex 4

The Martin Company will assume financial responsibility for all special nuclear materials received and will pay to the Commission the presented use charge based on the value of the material until the material is returned to the latter.

A copy of the 1956 Annual Report of the Company is attached as Appendix E.

III. Pursuant to Section 70.32, The Martin Company stipulates that:

(1) Title to all special nuclear material shall at all times be in the United States.

(2) No right to the special nuclear material shall be conferred by the license except as defined by the license.

(3) Neither the license nor any right under the license shall be assigned or otherwise transferred in violation of the provisions of the act.

(4) All special nuclear material shall be subject to the right of recapture or control reserved by section 108 and to all other provisions of the act.

(5) No special nuclear material may be used in any utilization or production facility except in accordance with the provisions of the act.

(6) The licensee shall not use the special nuclear material to construct an atomic weapon or any component of an atomic weapon.

(7) The licensee will hold the United States and the Commission harmless from any damages resulting from the use or possession of special nuclear material by the licensee.

(8) The license shall be subject to, and the licensee shall observe, all applicable rules, regulations, and orders of the Commission.

I certify that the statements made in this application and its attachments are true, complete and correct to the best of my knowledge and belief, and are made in good faith.

THE MARTIN COMPANY

BY: Tibor F. Nagey

Tibor F. Nagey
General Manager
Nuclear Division
Baltimore 3, Maryland

Subscribed and sworn to before me this 6th day of December, 1957.

Henrietta Marie Peters

Notary Public

My commission expires May 4, 1959.

APPENDIX B

DESCRIPTION OF PROCESSES EITHER DEVELOPED OR BEING DEVELOPED

(1) Stainless steel clad plates enclosing enriched uranium metal foil, Form V.

The process is diagrammed in the flow sheet for Form V, Appendix B. Material is received from processor in clean flat strips of foil, (Form VI) cut to size and enclosed in polyethylene bags. It is stored in birdcage boxes, 12" x 12" x 34" in lots not exceeding 1000 grams of U235 per container. Batches not exceeding 500 grams of contained U235 are withdrawn from storage vault, (Work Area 1a) and transferred by courier to Work Area 10 for assembly between stainless steel plates. Assembly is seam welded, evacuated at a low temperature and a final end seam weld made in Work Area 10. After radiography in Work Area 7, batches of plates will be autoclaved in Work Area 22 to determine porosity reliability.

Destructive and non-destructive testing will be performed on selected plates in Work Area 11.

(2) Stainless steel clad tubes enclosing fuel marrow of enriched uranium dioxide-stainless steel cermet (Form IV).

A description of the ~~process~~ destroyed & superseded by new Appendix "F" 1 pg. process is contained in the confidential manual, MND-1069 which is furnished as a supporting document to this application, (Appendix F). A flow sheet for the process is also included in Appendix C.

(3) Aluminum and aluminum alloy clad tubes enclosing pressed UO_2 -Al blended compacts (Form VIII).

Enriched uranium dioxide is blended with three parts by volume of powdered aluminum in Work Area 2. This blend is compacted to pressed bushings in Work Area 5. The bushings are assembled on a tube of aluminum or aluminum alloy and a second tube is passed over the bushings to complete the assembly. The assembly is swaged and drawn in Work Area 4 and then annealed to complete the metallurgical bonding in Work Area 5. Cleaning of the finished tubes is accomplished in Work Area 9. After radiography in Work Area 7, the assembly is sheared to size (Work Area 4) and the ends seam-welded in Work Area 10. Radiography, non-destructive testing, and porosity testing are done in Work Areas 7, 11 and 20 respectively to complete the tube manufacturing process. Brazing and welding of sealed tubes into bundles will be done in other facilities at Plant I under security and health safety safeguards required.

(4) Stainless steel cladsfilled with pressed compacts of uranium dioxide or uranium dioxide and thoria (Form XI).

Uranium dioxide powder of low enrichment in the isotope U235 is pressed into pellets. These pellets are assembled in stainless steel tubes and the interstices filled with a liquid metal to provide for efficient heat transfer between the fuel and the outside tube.

(An alternate method using ground pellets fitting to close tolerances in the tube may be used.)

The ends of the tubes are welded in Work Area 10 and the completed tubes are radiographed, porosity tested and cleaned.

IE 07			Docket Region 1	
NRC Region 1	various	1-25-1995	To: Martin Marietta NRC	
Teledyne	SNM-849	3-25-1975	To: NRC From: Teledyne	

Record / Docket Number	
A/44 – 70-58	2/1/60 – license amendment request SNM-53. Martin to AEC adds Plutonium Beryllium source for Critical Facility (KC) experiments. Indicates details on the Critical facility can be found in Martin Nuclear Division documents MND-1110, 1111, 1112, and 1157, and revised Criticality Manual MND-1063.
A/45 – 70-58	No date (1960)– Attachment 1 to above license amendment. Documents fabrication of uranium-aluminum alloy fuel elements (not clear whether in Building KC). Described fuel core assembly process– aluminum-uranium cores, hot-rolled in work area 17, punched from billets in work area 35, and assembled into plates in work area 41. Also documents testing consisting of radiography in work area 23, non-destructive testing in work area 25, and blister-annealing in work area 37.
A/46 – 70-58	3/4/60 - Telegram communication Martin Co. to AEC – requested the AEC's approval of above license amendment be expedited ahead of complete amendment.
A/47 – 70-58	3/11/60 - Telegram communication Martin Co. to AEC – requested the AEC's approval of above license amendment be expedited due to contract Martin had to supply fuel elements by May 4, 1960.
A/48 – 70-58	3/18/60 – Martin Company to AEC, clarification regarding sections of Martin Criticality Manual MND-1063 which had been revised. Indicates storage of PM-1 and ANPP fuel elements, and ERDL foil containers. (Building KC)
A/49 – 70-58	3/23/60 – Martin Co. to AEC – Indicates intent to replace original letter dated 2/9/60, due to misunderstandings which have held up approval. Clarification provided as to plan to fabricate uranium-aluminum alloy fuel elements, and attaches a new Nuclear Division report (MND-2330) covering health safety aspects of this work. Indicates there was a storage room in Building KC, 22 ft. x 13 ft. x 11 ft high, and walls of reinforced concrete 9 inches thick. The birdcages (storage containers for source materials) were placed on racks along the walls at least 17 inches above the floor to avoid flooding. Storage racks for fuel elements were located in the center of the room.
A/50 – 70-58	3/25/60 – AEC to Martin Co. recommending approval of the 3/23/60 amendment. Discusses SNM process flow and procedures (mass limits and concentration controls) to avoid criticality. (KC)
A/51 – 70-58	3/30/60 – Re: Amendment to SMN 53 (from 3/23/60): Internal AEC from Chief of licensing branch to hazards evaluation branch requesting review of applicants procedures to avoid accidental criticality. (KC)
A/52 – 70-58	3/30/60 – AEC Analysis and Findings responding to above request for review. Approval of amendment was recommended based on adequate safety procedures and experience of applicant. (KC)
A/53 – 70-58	4/5/60 - Form AEC-401 Amended SNM license, SNM-53 for U-235 as uranium oxide, and plutonium Pu-239 as Pu-Be source. (KC)
A/54 – 70-58	4/18/60 – (unspecified building) Martin Company to AEC, request for amendment to Byproduct Material License 19-1398-19. Changing maximum radioactivity of

	Cobalt-60 source to 10 curies.
A/55 – 70-58	4/18/60 – no license #/bldg. named. Internal MND safety calculation for storage boxes holding U-235 under flooded conditions.
A/56 – 70-58	04/20/60 – Re: Amendment to SMN 53 (request dated 4/18/60): Internal AEC from Chief of licensing branch to hazards evaluation branch requesting review of safety of Martin Company storage of fuel plate assemblies in cardboard and wood.
A/57 – 70-58	4/28/60 - no license #/bldg. named. Martin Company to AEC requesting amendment to source material license C-4283 to increase amount of Thorium-Magnesium Alloy from 75,000 to 100,000 pounds.
A/58 – 70-58	5/3/60 – no license #/bldg. named. Request from Martin Company to AEC Division of Licensing for Amendment to Byproduct Material License 19-1398-19. Request was to use a Technical Operations, Inc. model 412 projector with an Iridium-192 (50 curie) source.
A/59 – 70-58	5/5/60 – AEC licensing branch to Martin Company. Approval of 4/28/60 amendment to license C-4283 to increase amount of Thorium-Magnesium Alloy from 75,000 to 100,000 pounds.
A/60 – 70-58	6/10/60 – (SNM-53) Recommends approval of 4/18/60 Martin Company request to approve shipping procedures for aluminum clad fuel elements in wood/cardboard containers. Mentions shipment to University of California or University of Washington.
A/61 – 70-58	6/17/60 – MND request for amendment to SMN-53 further revising 4/5/60 amendment for Pu-Be source, to add Plutonium-alpha source to be used for instrument calibration purposes. Includes by attachment MND plutonium handling procedure.
A/62 – 70-58	6/21/60 – Writeup of the shipping procedure under SMN-53 for shipment of uranium-aluminum fuel elements via railcar to Universities of California and Washington.
A/63 – 70-58	6/22/60 – From Martin Company, Chairman Nuclear Control, regarding 1959 installation of radiation monitoring system at Middle River plant. (Building D).
A/64 – 70-58	6/28/60 – (SNM-53) Memorandum from AEC hazards evaluation branch to licensing branch regarding shipment of fuel elements via railcar to Universities of California and Washington. Indicates the AEC reviewed plan for shipping and recommended additional procedures be implemented to ensure radioactive fuels elements are not commingled with other radioactive materials.
A/65 – 70-58	6/28/60 – Internal communication from AEC hazards evaluation branch to licensing branch indicating the additional information requested by AEC 6/10/60 for SNM-53 amendment.
A/66 – 70-58	7/22/60 – AEC recommends approval of 6/17/60 amendment request to use plutonium alpha source as calibration standard. Also approves the request for shipping uranium-aluminum fuel elements to Universities of California and Washington.
A/67 – 70-58	7/26/60 – Form AEC-401, for amendment to SNM-53, adding the plutonium alpha source as calibration standard. The SMN-license now includes up to 500 kg. of U-235, 150 grams of Pu-239 as a Pu-Be neutron source, and 0.7 mg. Pu-239 as a Pu-alpha source. Location – Middle River Plant, Middle River, MD.
A/68 – 70-58	8/25/60 – no license #/bldg. named. Martin Co. to AEC requesting extension of

	license C-4283 (source material license) from 9/30/60 to 12/31/60.
A/69 – 70-58	10/11/61 (docket date) – Notice of Special Meeting of Stockholders: regarding the consolidation of American-Marietta Company with The Martin Company. Includes a prospectus of each company; describes the Martin Nuclear activities.
A/70 – 70-58	9/9/60 – AEC to Martin Company, issuance of license C-4283 (source material license) for the possession of 100,000 pounds of thorium magnesium alloy containing not more than 4-percent thorium. Subsequent document indicates this material was for fabricating the outer skins of Titan I missiles.
A/71 – 70-58	4/19/61 – Source material license C-4283 - AEC Radiation Safety Branch radiation safety check (inspection report). Indicates 150,000 pounds or thorium magnesium alloy stored at any given time. Indicates limited volumes 3,000 (no units) liquid waste disposed in or transferred to sewer, marked as "adequate" on inspection form.
A/72 – 70-58	12/1/60 – Martin Company to AEC, request for further amendment to SNM-53, in reference to storage of 500 kg of U-235 in licensed vault. Requests addition of storage facilities for feed material and finished products. Includes storage in an area of 8 former munitions bunkers known as the "revetment" area. Each bunker measured 15 x 13 x 11 ft. high. Plans for storage of 75 kg. U-235 in each of 3 of the bunkers. No maps or photos included.
A/73 – 70-58	12/5/60 – Re: Amendment to SMN 53 (request dated 4/18/60): Internal AEC from Chief of licensing branch to hazards evaluation branch requesting review of procedures in place to avoid accidental criticality in storage areas referenced in 12/1/60 request.
A/74/75 – 70-58	1/12/61 – AEC facilities and materials handling branch to MND nuclear facilities safety. Requests detailed information on the types of materials and conditions they would be stored in within the 3 former ammunition bunkers. Requests that alarmed detection sensors should be installed in each of the bunkers, and requests additional information on the manner of storage in the outdoor fenced area near Building D.
A/76 – 70-58	1/30/61 – AEC internal communication nuclear materials branch to criticality evaluation branch requesting evaluation of procedures to avoid criticality in storage areas/bunkers.
A/77 – 70-58	2/1/61 – AEC internal communication clarifying the additional information that should be requested regarding the storage areas in Martin Co. request dated 12/1/60.
A/78 – 70-58	2/17/61 - AEC internal communication criticality branch to nuclear materials branch. Indicates review of accidental criticality prevention was completed and the storage areas are safe under even flooded conditions due to the mass limitations.
A/79 – 70-58	2/20/61 – AEC Analysis and Findings – recommends approval of 1/17/61 MND request to amend SNM-53 by increasing the U-235 quantity in the melt and ingot process during fabrication of uranium-aluminum fuel plates.
A/80 – 70-58	2/20/61 – Form AEC-401 for SMN-53, increases U-235 quantity to 500 kgs. (for Middle River Plant, MD)
A/81 – 70-58	3/9/61 – re: license C-4283, Martin Company request to AEC to increase the limit of thorium-magnesium alloy (4% thorium) from 100,000 lbs. to 150,000 lbs. and requesting an extension of the license from 9/30/61 to 9/30/62.

A/82 – 70-58	3/31/61 – AEC to Martin Co. acknowledgement of receipt of 3/9/61 request to amend license C-4283. Requests additional information including detailed descriptions of the activities to be performed, and the quantities and disposal methods of radioactive waste.
A/83 – 70-58	4/12/61 – Martin Company to AEC re: 3/31/61 AEC request for additional information in connection with above license amendment. Lists activities to be performed including machining, cleaning of alloy plates using trichloroethylene and chromic acid pickle, and finishing with dichromate treatment and zinc chromate primer (as outer skins for Titan I missiles). Describes wastes generated including chips, clippings, dust, etc. accumulated at 3,000 lbs. maximum quantity. Solid wastes removed at 6 to 10 month intervals and sold to a licensed scrap dealer. Liquid wastes were analyzed periodically and were found safe to dispose in the sanitary sewer.
A/84 – 70-58	4/20/61 – from AEC to Martin Company re: new license identification system, source material license STB-187 replaced C-4283.
A/85 – 70-58	4/20/61 – AEC to Martin Co. approval of storage of 100,000 lbs. thorium-magnesium alloy under license STB-187.
A/86 – 70-58	7/21/61 – Martin Co. to AEC – letter requests amendment to by-product material license 19-1398-19 (sealed sources for radiography) to permit the use of by-product material for radiography (Iridium-192 and Cobalt-60) at PM-1 reactor being assembled near Sundance, Wyoming. Requests by-product material be shipped from Middle River to point of commercial delivery nearest the reactor site and transported by the user to the reactor site.
A/87 – 70-58	8/4/61 – AEC memorandum criticality branch to source & special nuclear materials branch. Martin Co. submitted application 7/31/61 to amend SNM-53 to add highly enriched uranium oxide powder in spherical form, maximum 4,000 grams. This memorandum indicates the safety controls are adequate to prevent accidental criticality.
A/88 – 70-58	9/1/61 – Martin Co. to AEC request to amend byproduct material license 10-1938-19 to include use of a projector containing 50 curies of Iridium-192.
A/89 – 70-58	10/6/61 – Inventory of all Martin Company licenses for byproduct material, by location. The following licenses are listed for the Middle River Plant location: 19-1398-1 – sealed sources for calibration at the Critical Experiment Facility (Bldg. KC); also, includes photos of bunkers to be used as referenced in above SNM-53 amendment request (A-72 to A-76). 19-1398-3 – sealed cobalt sources 19-1398-9 – sealed sources for instrument calibration 19-1398-12 – sealed sources Krypton-85 (light source) 19-1398-14 – research & development 19-1398-15 – radioisotopic heat sources 19-1398-17 – sealed strontium sources for calibration 19-1398-18 – sealed sources for density gauge 19-1398-19 – sealed sources for radiography 19-1398-20 – for preparation of sealed source for irradiation 19-1398-21 – thermoelectric converters 19-1398-23 – sealed H3 standard light source 19-1398-25 – sealed source density gauge

	Also references a fenced outdoor storage area (on concrete slab) for nuclear materials scrap on the south side of Building D, including storage of up to 100 kg of U-235 and other scrap in drums.
A/90 – 70-58	10/10/61 – Martin Co. to AEC, letter indicating Martin Co. will become Martin-Marietta, but the management and operations governed under licenses STB-187, SMB-112, and SUB-313 would remain unaffected.
A/91 – 70-58	10/17/61 - Martin Co. to AEC, letter indicating the consolidation to Martin-Marietta had occurred and requesting transfer of licenses to the name of the new corporation.
A/92 – 70-58	11/16/61 – letter from AEC to Martin Company indicating the license SMN-53 had been transferred to the new corporation name of Martin-Marietta. (revised license attached).
A/93 – 70-58	1/24/62 – Martin-Marietta to AEC – request to amend expiration date only for by-product material license 19-1398-19.
A/94 – 70-58	3/23/62 – AEC memorandum documenting department of licensing & regulation meeting with Martin Nuclear Division to discuss amendment to SNM-53. Martin-Marietta requested to increase the production capacity for spheroidizing Uranium oxide powder. The amendment would include an increase in the amount of wastewater due to increasing the size of the washing apparatus to two washing towers. Recommends limits on U2-O2 in air and water filters.
A/95 – 70-58	3/27/62 – (no bldg. name.) AEC internal communication nuclear materials branch to criticality evaluation branch requesting evaluation of procedures to avoid criticality with amendment to SNM-53 requested by MND on 3/22/62.
A/96 – 70-58	4/2/62 – AEC approval of MND amendment to SNM-53 to increase the production and washing capacity for the uranium-dioxide powder.
A/97 – 70-58	5/8/62 – (no bldg. name.) AEC internal communication nuclear materials branch to criticality evaluation branch requesting evaluation of procedures to avoid criticality in amendment requested by Martin-Marietta on 5/3/62.
A/98 – 70-58	5/17/62 – same as above.
A/99 – 70-58	5/24/62 – (no bldg. name.) AEC internal communication nuclear materials branch to process evaluation branch requesting review of containers proposed in connection with the drop-hammer test.
A/100 – 70-58	6/11/62 – AEC Memorandum re: amendment to SNM-53 (requested 5/8/62) for shipment of uranium-dioxide stainless steel clad fuel plates to the National Nuclear Energy Department in Rome, Italy.
A/101 – 70-58	6/14/62 - AEC Memorandum re: Martin-Marietta request to increase mass limits of uranium-dioxide powder under license SNM-53 from 800 grams to 3.5 kilograms.
A/102 – 70-58	9/4/62 – transmittal letter nuclear materials branch to process evaluation branch indicating materials attached were being provided to aid evaluating shipping procedures.
A/103 – 70-58	9/11/62 – AEC letter acknowledging AEC completed review of shipping procedures or shipment to Rome, Italy, and approved pending reassurance that the Italian government would ensure subsequent transport is done safely.
A104 – 70-58	10/10/62 – (Bldg. KQ?) Letter from Enforcement Branch AEC to Martin-Marietta. Dr. McHerney of the Metallographic Laboratory had an elevated film badge reading of 100 rem over 13 weeks; however it was concluded that the badges had

	been stored too close to uranium sources.
A/105 – 70-58	11/23/62 – AEC internal memorandum documents MND request to ship and receive two central core fuel bundles of PM-3a elements to Andrews Air Force base.
A/106 – 70-58	1/29/63 – Martin Company request to AEC to renew two byproduct material licenses (19-1398-19 and 19-1398-27). Attachment from Martin Company describes chamber leak-testing. Nuclear Components Department named on license. Includes Thulium-170 and Strontium-Yttrium 90 on license, in addition to Iridium and Cobalt.
A/107 – 70-58	4/16/63 – AEC Division of Compliance, transmittal of Type "B" incident, explosion of spheroidizing room. Spheroidizing operation equipment was lost for more than one week. Failure of MND to determine whether a release of UO2 occurred through the stack
A/108 – 70-58	4/19/63 – AEC Memorandum, division of licensing and regulation to compliance division describes explosion of spheroidizing room. (No Bldg. is named). States one employee was contaminated and the area was decontaminated.
A/109 – 70-58	
A/110 – 70-58	4/24/63 – AEC compliance division to division of licensing and regulation regarding a Type "B" incident, explosion, tagged SNM-53. States a memorandum was transmitted on April 19, 1963 regarding an investigation report dated April 16th, 1963, which included the urinalyses and film badge results for a licensee employee. Smear survey results of the filter system at the licensee's facility are also included.
A/111 – 70-58	4/26/63 – AEC enforcement branch to Files regarding license SNM-53 describing that no items of noncompliance were found during the investigation and no enforcement action is appropriate.
A/112 – 70-58	4/30/1963 – Criticality Evaluation Branch (DLR) to Source and Special Nuclear Materials Branch (DLR) regarding an application dated March 29, 1963 for procedure to be followed in using a "work box" both for fuel storage and general storage at a processing location. They conclude that the procedures described are adequate to prevent a condition of accidental criticality for fuel material, but are reminded that any fuel differing in enrichment or chemical and physical form must be covered for a request for a license amendment.
A/113 – 70-58	6/17/63 -- Criticality Evaluation Branch (DLR) to Source and Special Nuclear Materials Branch (DLR) states the review and acceptance of the use of 50 in-process storage tanks
A/114 – 70-58	7/1/63 – Criticality Evaluation Branch to Files regarding a meeting held on June 25, 1963 to discuss a subject license amendment application regarding the stability and structural integrity of a shipping container for pathfinder fuel elements.
A/115 – 70-58	7/2/63 – Follow up memorandum of A/114 stating the criticality evaluation branch reviewed the application requesting the use of shipping containers for the shipment of Pathfinder fuel elements. The use of railway express for the shipments was stated by the applicant, but the CEB can not conclude that the use of railway express will prevent comingling with other materials. The CEB approves the proposed procedures subject to the use of railway express.
A/116 – 70-58	7/19/63 – Another follow up memorandum of A/115 stating the subject application has been reviewed and concluded there is insufficient information to

	determine adequacy of procedures to prevent a condition of accidental criticality. This memorandum describes nine areas where additional information is required to continue analysis
A/117 – 70-58	7/30/63 – AEC to fuel processing branch regarding the needed review of the structural integrity of the aforementioned shipping container for pathfinder fuel
A/118 – 70-58	7/30/63 – AEC letter regarding the shipment of Pathfinder fuel elements from Baltimore to Sioux Falls, South Dakota. The use of vehicle or courier escort was determined not feasible, so REA Express was contacted and enclosed is the reply letter describing the ability to handle the said shipment.
A/119 – 70-58	8/6/63 – AEC memorandum requesting the review of the letter dated July 30, 1963 (above) from the standpoint of adequate control to prevent comingiling of SNM shipments. Also states the Martin container and shipping procedures may be used by Pathfinder to return any rejected elements.
A/120 – 70-58	8/9/63 – AEC memorandum stating the review of the aforementioned letter dated July 30, 1963 determining the letter from REA express is not adequate evidence of compliance with certain provisions. AEC requests a written certificate from REA express describing that the shipment will meet procedure to ensure the requirements of shipment are followed
A/121 – 70-58	8/13/63 – AEC internal memo describing the requests stated above regarding the shipment of Pathfinder fuel
A/122 – 70-58	12/11/63 – AEC memorandum describing the review of the application dated July 19, 1963, also includes specific revisions suggested to the application
A/123 – 70-58	1/28/64 – AEC to Martin company nuclear division describing the application dated March 28, 1963 for renewal of license SNM-53. The results of the discussion require the re-submission of the application, including covering the 20 points of additional information enclosed in this document.
A/124 – 70-58	2/14/1964 – Martin company to AEC regarding the proposed amendment 20 to SNM-53 including the proposed use shipping containers and methods for the shipment of excess uranium bearing material for reprocessing. Approval from AEC is requested for this amendment
A/125 – 70-58	2/21/64 – Martin company to AEC requesting that license 19-1398-27 be combined with 19-1398-19 thereby eliminating 19-1398-27 since they are both similar. Additional information needed for the application is also included
A/126 – 70-58	2/25/64 – Martin company to AEC requesting the establishment of an allocation for enriched uranium to assure proper authorizations are in effect for withdrawal in April
A/127 – 70-58	2/25/64 – summary of telephone conversation between Martin company and C. Keller regarding the status of the application dated 2/14/64 to ship air filters containing uranium
A/128 – 70-58	3/2/64 – AEC to Martin corporation describing Source Material License number STB-187 is due to expire on April 30, 1964
A/129 – 70-58	3/3/64 – AEC requesting the review of the martin application dated 2/14/64(filters containing uranium) with reference to the structural integrity and shoring of the shipping containers.
A/130 – 70-58	3/20/64 – Martin company to AEC acknowledging the expiration of license STB-187 and executing the termination of said license due to no longer needing the application at the Middle River facilities

A/131 – 70-58	3/24/64 – AEC internal, regarding the letter from 3/20/64 (shipment of air filters) requesting review from the standpoint of criticality control.
A/132 – 70-58	4/6/64 – AEC internal responding to the above request for review of shipment of air filters. AEC has no further objections, but informs Martin some calculations were erroneous and in need of reviewing
A/133 – 70-58	4/8/64 – AEC internal regarding Martin Company requesting amendment of SNM-53, requesting review of the application from the standpoint of criticality control
A/134 – 70-58	4/14/64 – Martin company to AEC, Martin centralized all Radioactive Materials Management within the Contracts Department.
A/135 – 70-58	4/15/64 – AEC internal regarding the Martin Company application dated 4/1/64. AEC reviewed the application for SNM-53 to authorize the fabrication of a nuclear core. Inlcuded are comments regarding said application
A/136 – 70-58	4/29/64 – AEC internal, regarding further information in reply to letter dated 4/20/64, review of the application from the standpoint of criticality control is requested
A/137 – 70-58	4/30/64 – AEC to Martin company acknowledging Martin's letter dated 4/14/64 regarding the appointment of C. Keller as Nuclear Accountability and Licensing Representative for Martin Company.
A/138 – 70-58	5/15/64 – AEC internal, regarding Martin company application dated 5/11/64. Review concludes the procedures described in application for amendment of SNM-53 to authorize the shipment of uranium solutions are adequate.
A/139 – 70-58	6/9/64 – AEC internal, regarding Martin company requesting authorization for Class III shipment of 15 drums of uranium solution, 21 drums of solid and powder uranium scrap and six metal containers for large ductwork filters. AEC has no objections, subject to approval by C. Beck regarding the structural integrity of the container
A/140 – 70-58	6/12/64 – AEC internal, Martin company application dated 6/9/64 reviewed, requesting authorization for shipment of ten containers in two rows of five each of uranium scrap. AEC has no objections, but subject to C. Beck review (like above)
A/141 – 70-58	6/29/64 – Martin company revision request for shipment of scrap to Erwin, Tennessee
A/142 – 70-58	6/22/64 – AEC internal, describing a visit to NFS in Tennessee and the shipment of filters received from Martin corporation. Comments describe a question concerning the ability of the shoring to withstand a one hour fire test as well as the filters containing more uranium than previously approved, a further discussion is requested.
A/143 – 70-58	6/22/64 – AEC internal hand written note regarding the shipment of filters containing U-235 from Martin to Tennessee.
A/144 – 70-58	7/7/64 – Martin company to AEC regarding proposed amendment 22 to SNM-53. Policy change in AEC to establish all health and safety aspects of special nuclear material processing results in Martin Corporation requesting approval for several processing steps previously approved by the New York Operations office of the AEC.
A/145 – 70-58	7/8/64 – AEC internal, regarding letter 8/7/64 from Martin Company requesting amendment of SNM-53 to include particle coating, extrusion, and hydrostatic pressing of enriched uranium be reviewed from the standpoint of criticality control

A/146 – 70-58	7/20/64 – Martin company to AEC, Martin requesting by product material license 19-1398-20 be amended to permit the measuring of basic spectrum derived from radioactive decay of several radioisotopes, includes description of the procedures to be used
A/147 – 70-58	7/22/64 – AEC internal, regarding Martin company application dated 7/9/64 and includes a list of discussion points pertaining to nuclear safety
A/148 – 70-58	7/28/64 – AEC internal, regarding Martin company application 7/7/64, supplemented 7/20/64. Describes that AEC reviewed the application and can not agree with the statement that uranium particle coating be termed as a "dry" operation, AEC includes recommendations to either limit the maximum uranium-235 within coating or provide a detailed nuclear safety analysis demonstrating the safety of the proposed operations
A/149 – 70-58	8/12/64 – AEC to Martin company, same content as A/148, see above
A/150 – 70-58	8/17/64 – AEC internal, regarding Martin company application dated 8/4/1964. Describes the review of the amendment of SNM-53 to authorize the fabrication of a nuclear core employing U (5%) O2 pellets.
A/151 – 70-58	8/19/64 – AEC internal, regarding Martin company application 8/14/64. AEC reviewed the application for authorization to ship U(5%) O2 pellets and, subject to approval by C. Beck, have no objections
A/152 – 70-58	8/26/64 – AEC internal, regarding Martin company additional information dated 8/19/64. AEC reviewed the information and concludes that cleaning operations are safe from uranium build up and have no objection to the described storage or the handling procedures for scrap
A/153 – 70-58	8/27/64 – AEC to Martin company, describing SNM-53 being amended to authorize shipment of uranium oxide pellets from Erwin, Tennessee to Baltimore, Maryland in accordance with procedures described in letters dated 8/14/64 and 8/26/64
A/154 – 70-58	8/28/64 – AEC to Martin company, regarding SNM-53 amendment described above. Describes a typographical error in the 8/6/64 submittal
A/155 – 70-58	No date, AEC to Martin company asking for three copies of Martins latest annual financial report
A/156 – 70-58	9/9/64 – Martin company to AEC, complying to the above request and enclosing three copies of the annual financial report
A/157 – 70-58	9/24/64 – AEC internal, regarding Martin company application dated 9/11/64, stating AEC reviewed the request to increase in certain station limits and the inclusion of several new process steps and have no objections
A/158 – 70-58	9/29/64 – AEC to Martin company, regarding the further amendment of SNM-53 in accordance with the procedures described in the letters dated 8/4/64, 8/19/64, and 9/11/64
A/159 – 70-58	10/5/64 – AEC to Martin company, stating SNM-53 is amended to authorize uranium particle coating, tube extrusion and hydrostatic pressing of tubular fuel components in accordance with procedures described in letter dated 7/7/64 and telegram dated 7/20/64 subject to the maximum quantity of enriched uranium not exceed 350 grams
A/160 -- 70-58	10/28/64—Western union telegram for the request of approval for shipment of UO2 from Middle River, MD to Battelle Memorial Institute in Columbus, OH.
A/161 – 70-58	10/30/64 – AEC internal, regarding Martin company TWX of 10/28/64. AEC states

	they have reviewed the application requesting authorization for shipping one kg enriched with UO2, approve the shipping container drop tests but cannot approve the “uncontrolled” shipment plan.
A/162 – 70-58	11/2/64 – AEC internal, regarding chronologies of actions on timely renewal applications. Describes the actions taken for 14 licenses that expired and are being continued on a timely renewal basis
A/163 – 70-58	11/16/64 – AEC to Martin company, describes the telephone conversation on 11/2/64 stating the withdrawn request dated 10/28/64 to ship 1 kg of UO2 and that no further action would be taken
A/164 –70-58	12/4/64 – AEC to Martin company, regarding SNM-53 being further amended to authorize the storage of MH-1A fuel tubes in accordance with procedures described in the licensee’s application dated 11/23/64
A/165 – 70-58	12/4/64 – AEC internal, regarding Martin company application dated 11/23/64, stating they have no objection to the request for the authorization for the temporary storage of fuel tubes containing UO2 pellets.
A/166 – 70-58	12/4/64 – Kramer-Consolidated Freight Lines, Inc to Martin company, Kramer stating that they have a program for the proper handling of radioactive material and do not intermix radioactive shipments
A/167 – 70-58	12/11/64 – AEC internal, regarding Martin company nuclear material license SNM-53. Includes the report of a nuclear safety inspection conducted at the Baltimore facilities on 11/12/64
A/168 – 70-58	12/18/64 – AEC to Martin company, stating the 3/28/63 license SNM-53 is renewed and will expire on 6/30/65
A/169 – 70-58	12/31/64 – AEC internal, regarding Martin company PU-238 criticality limits. Describes a telephone conversation between Martin and AEC, Martin asked about criticality requirements concerning PU-238 that AEC had in place, AEC did not have any established as of yet
A/170 – 70-58	1/8/65 – Telegram from Martin to AEC, stating Martin will be unable to meet target date for new submission of SNM-53 that AEC requested, application is in the last stages of editing
A/171 – 70-58	1/21/65 – AEC internal, regarding the compliance inspection report for Martin company for the inspection conducted 11/12/64. Describes that AEC does not plan to correspond with Martin regarding the inspection as no items of noncompliance were found
A/172 – 70-58	1/28/65 – Martin company to AEC, regarding the revised application for Martin license SNM-53, Martin submits the revised Martin Marietta corporation application for SNM-53
A/173 – 70-58	2/24/65 – Martin company to AEC, regarding the shipment of special nuclear material Argonne National Laboratory, requesting AEC approval for further use of a container
A/174 – 70-58	2/24/65 – AEC byproduct material license for Martin Marietta Corp, license 19-1398-33
A/175 – 70-58	3/11/65 – AEC internal, regarding Martin company application dated 3/3/65, AEC reviewed the request for authorization for the storage of MH-1A fuel elements and have no objection to the request
A/176 – 70-58	3/12/65 – AEC to Martin company, describing SNM-53 is further amended to authorize storage of unirradiated MH-1A fuel elements, storage on elements after

	use in criticality experiments is still under consideration
A/177 – 70-58	3/29/65 – Mason Dixon Lines, inc to Martin company stating Mason Dixon will not transport shipments of radioactive materials in the same trailer with other shipments of radioactive materials
A/178 – 70-58	4/12/65 – Martin company to AEC regarding the shipment of SNM to Battelle Memorial Institute in Columbus, OH. Martin requesting approval for shipment of U-235 to BMI in OH
A/179 – 70-58	4/12/65 – Martin company to AEC regarding the shipment of SNM to Nuclear Fuel Services in Erwin, Tennessee. Martin requesting AEC approval for use of the container previously used in a drop test to ship excess fuel from the Pathfinder program to NFS in Tennessee
A/180 – 70-58	4/14/65 – AEC to Martin company, describes AEC response to Martin letter from 2/24/65 requesting amendment of SNM-53 to authorize shipment of uranium oxide powder
A/181 – 70-58	4/15/65 – Martin company to AEC regarding the storage of fuel elements and how Martin needed approval from AEC by 5/5/65
A/182 – 70-58	4/20/65 – Martin company to AEC, Martin encloses six copies of the Martin Marietta corporation annual report for 1964
A/183 – 70-58	4/26/65 – AEC to Martin explaining the request to store MH-1A fuel elements after use in critical experiments will be transferred to a different branch (Division of Reactor Licensing)
A/184 – 70-58	4/29/65 – AEC to Martin Company stating SNM-53 further amended to authorize the shipment of U-235 from Baltimore,MD to Erwin, TN
A/185 – 70-58	4/29/65 – AEC internal, regarding Martin company application dated 4/12/65. AEC reviewed the applications for shipments of U-235 and have no objections
A/186 – 70-58	5/28/65 – AEC to Martin company, AEC further amends SNM-53 to authorize storage of MH-1A fuel elements after use in critical experiments
A/187 – 70-58	6/3/65 – Martin company to AEC, regarding the shipment of excess SNM from Martin Company to Uranium Reprocessing Facility. Martin requests AEC approval for this shipment
A/188 – 70-58	6/16/65 – AEC internal, regarding Martin company consolidated renewal application dated 1/28/65. AEC reviewed the application for renewal of SNM-53 and requests more information to continue their review
A/189 – 70-58	6/30/65 – AEC to Martin company, amending SNM-53 to list expiration date as 8/30/65 and the request for renewal for SNM-53 for the 3 year period is under consideration
A/190 – 70-58	7/13/65 – AEC to Martin company, regarding the renewal of SNM-53, AEC requests more information for their review
A/191 – 70-58	7/15/65 – Martin telegram to AEC, describing the content of the phone conversation involving containers and filters
A/192 – 70-58	7/16/65 – Martin telegram to AEC, describing specifics on solution containers and U-235 content in filters
A/193 – 70-58	7/16/65 – AEC to Martin company, describing the amendment of Condition 13 of License 19-1398-33 regarding personnel who will be supervising byproduct material
A/194 – 70-58	7/19/65 – AEC internal, regarding Martin company application dated June 3, 1965. AEC reviewed the application for authorization for the exclusive use shipment of

	scrap material, they conclude that the shipment is safe
A/195 – 70-58	7/20/65 – AEC to Martin company, authorizes the shipment of U-235 from Baltimore, MD to Erwin, TN
A/196 – 70-58	8/10/65 – AEC to Martin company, notice that SNM-53 is set to expire on 9/30/65
A/197 – 70-58	9/2/65 – Martin company to AEC, regarding the AEC letter from D. Nussbaumer dated 7/13/65, Martin submits revised pages for the renewal of SNM-53
A/198 – 70-58	9/20/65 – AEC internal, regarding Martin company application dated 9/2/65. AEC has no objections to the information presented but expresses concerns towards evaporator concentration of liquid radioactive waste
A/199 – 70-58	9/30/65 – AEC to Martin company, AEC amends SNM-53 expiration date to 12/30/65
A/200 – 70-58	9/30/65 – Martin company to AEC, regarding renewal of SNM-53, included are references containing additional information requested by AEC
A/201 – 70-58	10/7/65 – Martin company to AEC, Martin requests that Byproduct Material License 19-1398-33 be amended to include personnel as an authorized user for the transport and demonstration of a Martin product
A/202 – 70-58	10/18/65 – AEC internal, regarding Martin company application dated 9/30/65. Included are various responses to items pertaining to the application
A/203 – 70-58	11/18/65 – AEC to Martin, includes amendment to License 19-1398-33 with respect to Item 8A and Condition 15
A/204 – 70-58	12/1/65 – Martin company to AEC, Martin submits revised pages to further clarify the SNM-53 renewal application due 12/31/65
A/205 – 70-58	12/1/65 – Martin company to AEC, Martin submits proposed section VI Part B of SNM-53 for the purpose of obtaining license coverage for the shipment of MH-1A fuel elements between the Martin facilities at Middle River, MD and Fort Belvoir, VA
A/206 – 70-58	12/3/65 – Martin company to AEC, Martin submits revised pages for renewal of SNM-53 pertaining to the discussion in Bethesda on 12/1/65
A/207 – 70-58	12/15/65 – AEC internal, AEC reviewed the application for the shipment of MH-1A fuel elements and denies the request due to C. Beck indicating the tie-downs are inadequate to assure certain spacing in the event of an accident
A/208 – 70-58	12/16/65 – AEC internal, regarding applications dated 12/1/65 and 12/3/65. AEC reviewed the supplemental applications and due to the revisions has no further objections and recommends approval
A/209 – 70-58	12/22/65 – AEC internal. AEC reviews renewal application for renewal of SNM-53 and concludes to recommend renewal for SNM-53
A/210 – 70-58	1/7/66 – AEC to Martin company, regarding SNM-53 being renewed, includes SNM-53 as renewed
A/211 – 70-58	1/21/66 – Martin company to AEC, Martin requests AEC to replace a referenced submission with Section VI, Part B, of SNM-53 which detailed the revised methods for shipment of MH-1A fuel elements
A/212 – 70-58	2/3/66 – AEC internal, AEC reviewed application stated above and has no objections
A/213 – 70-58	2/4/66 – AEC to Martin, includes an amendment to SNM-53 pertaining to dates of renewal
A/214 – 70-58	7/6/66 – AEC to Martin, AEC informs Martin they are allocated uranium in the U-235 isotope, also includes arrangements for procurement of said material

A/215 – 70-58	8/15/66 – Martin to AEC, Martin requests the allocation of SNM for government fiscal year 1967 from AEC
A/216 – 70-58	8/24/66 – AEC Special Nuclear Material Draft form pertaining to the above allocation request by Martin
A/217 – 70-58	8/24/66 – AEC to Martin, AEC approves allocation of U-235 to Martin as previously described
A/218 – 70-58	9/26/66 – Martin company to AEC, Martin requests an amendment to SNM-53 to authorize the fabrication of a uranium oxide-metal hydride component
A/219 – 70-58	10/3/66 – Martin company to AEC, Martin includes a revised page III-D-1 which they believe will clarify the minor questions discussed during a meeting on 9/30/66
A/220 – 70-58	10/3/66 – AEC internal, describes the telephone call between C.Keller of Martin and K. Lauterbach on 9/30/66 to discuss application of 9/26/66
A/221 – 70-58	10/13/66 – AEC internal, describes telephone call on 10/11/66 regarding the criticality of 238 PU
A/222 – 70-58	10/14/66 – AEC internal, regarding application dated 9/26/66, AEC recommends further review of allowable numbers for storage containers used for storage of the hyrdided disks in question
A/223 – 70-58	10/14/66 – Martin to AEC, Martin submits revised copies of page IV-A-5 and figures I-B2, IV-A5, and V-E2 which define a new location for the nuclear storage area pertaining to SNM-53
A/224 – 70-58	10/24/66 – AEC internal, AEC reviews request stated above and as no objections
A/225 – 70-58	10/24/66 – Martin to AEC, Martin attaches page III-D-2A which defines limits of certain pellets in storage vaults at Middle River, MD, also pertains to SNM-53
A/226 – 70-58	10/28/66 – AEC internal, AEC disagrees with Martin information regarding the allowable number of units as read from Fig 22 and gives a recommendation for changes.
A/227 – 70-58	11/9/66 – AEC to Martin, AEC amends SNM-53 dated 9/26/66 but does not agree with 10/24/66 application described above but again recommends a revision
A/228 – 70-58	11/18/66 – Martin company to AEC, Martin submits three copies of the proposed amendment to Byproduct Material License 19-01398-20 to AEC for review
A/229 – 70-58	12/8/66 – AEC to Martin, AEC informs Martin they have completed their annual review of practices and procedures for the control of SS materials and conclude Martin does meet AEC requirements
A/230 – 70-58	12/14/66 – AEC to Martin, AEC acknowledges receipt of consolidation application for SNM-53 to deliver special nuclear material to a carrier for transport
A/231 – 70-58	12/14/66 – Martin to AEC, Martin recognizes AEC comments concerning the nuclear storage area and replies that they believe they are in compliance with subparagraph 70.24(a) of title 10 Code of Federal Regulations, Part 70
A/232 – 70-58	12/21/66 – AEC internal, regarding Martin company letter dated 12/14/66, thanking AEC for comments in the referenced letter concerning the new location of the storage area
A/233 – 70-58	12/27/66 – AEC internal, regarding Martin application dated 11/11/66, AEC reviewed the application and have no objection
A/234 – 70-58	1/11/67 – AEC to Martin, AEC enclosing amendment 71-1 to SNM-53 authorizing the delivery of SNM to a carrier for transport in the package designated as the Martin All Purpose container

A/235 – 70-58	1/31/67 – Martin to AEC, continued discussion of the nuclear storage area, includes references of letters back and forth from AEC to Martin
A/236 – 70-58	2/8/67 – AEC internal, Martin company letter dated 1/31/67 referring to new location of their nuclear storage area is enclosed
A/237 – 70-58	2/9/67 – AEC to Martin, AEC encloses a copy of a Notice of Rule Making published in the Federal Register on 2/3/67, concerning amendments to 10 CFR Part 70 specifying certain requirements for the safeguarding of SNM
A/238 – 70-58	2/14/67 – AEC to Martin, AEC amends SNM-53 dated 1/31/67 and 10/14/66 with dates for use
A/239 – 70-58	4/12/67 – Martin to AEC, regarding Title 10 Code of Federal Regulations Part 70, Martin requests approval of its procedures for the safeguarding of SNM
A/240 – 70-58	1/15/68 – Survey of SS material safeguards control at Martin Marietta Corporation, Middle River, MD.
A/241 –70-58	5/14/68 – Martin to AEC, regarding emergency plans, AEC asks Martin to participate in the re-evaluation of guidelines for the scope of plans and procedures required to cope with emergency situations
A/242 – 70-58	4/14/69 – AEC to Isotopes Incorporated, AEC approves request to amend SNM-53 to authorize a maximum quantity of 5000 grams of SNM
A/243 – 70-58	8/2/68 – Martin to AEC, regarding the transfer of SNM and source licenses. Explains that Isotopes, Inc, has acquired the Martin Marietta Corporation Nuclear Division effective 8/4/68
A/244 – 70-58	8/6/68 – Isotopes Inc to AEC, regarding a request for transfer of source and SNM license responsibility. Isotopes Inc states they will operate in the same facilities at Middle River, MD as the Nuclear Systems Division of Isotopes Inc.
A/245 – 70-58	8/19/68 – AEC internal, Notification of intended action regarding the transfer described above
A/246 – 70-58	9/3/68 – AEC to Isotopes inc, AEC informs Isotopes that the transfer is in accordance with the Atomic Energy Act of 1954
A/247 – 70-58	9/3/68 – AEC to Martin, further confirmation of the Isotopes Inc transfer described above
A/248 – 70-58	Date unreadable (1968) – AEC to Isotopes Inc, further notice of transfer of license to Isotopes Inc
A/249 – 70-58	12/9/68 – AEC to Isotopes, regarding notification of intended action for licensing, explains licensing action is necessary and will coordinate
A/250 – 70-58	9/12/68 – AEC to Isotopes, AEC reviews certain licensing activities with respect to nuclear materials safeguards with Isotopes due to the recent transfer
A/251 – 70-58	1968 – AEC to Isotopes, notice that SNM-53 expires on 12/31/68
A/252 – 70-58	11/13/68 – Isotopes to AEC, Isotopes expressing appreciation to AEC for the guidance provided during a meeting on 11/6/68, Isotopes confirms that they intend to submit the Fundamental Material Controls and Nuclear Materials Safeguards required in connection to SNM-53
A/253 – 70-58	12/68 – AEC to Isotopes, AEC encloses amendments to part 71, title 10, code of federal regulations
A/254 – 70-58	2/5/69 – Isotopes to AEC, Isotopes encloses the first portion of the Fundamental Material Controls and Nuclear Safeguards Procedures
A/255 – 70-58	2/24/69 – AEC to Isotopes, AEC responds to Isotopes application for renewal of AEC SNM-53 and requests Isotopes to submit a new application

A/256 – 70-58	4/9/69 – AEC internal, regarding Isotopes application dated 4/4/69 involving the fabrication of UO2 into test fuel pins, AEC recommends approval
A/257 – 70-58	4/10/69 – AEC to Isotopes, notification of intended action for application dated 4/4/69, no action needed
A/258 – 70-58	4/14/69 – AEC internal, enclosed is a copy of a letter from P. Knapp of Isotopes to D. Harmon dated 4/4/69 requesting a modification to SNM-53
A/259 – 70-58	4/14/69 – AEC internal, Notification of intended action for Isotopes application dated 4/8/69, licensing action is necessary
A/260 – 70-58	4/21/69 – Isotopes memo regarding safeguards inspection no. SO-I-5, describes resulting conclusions
A/261 – 70-58	4/21/69 – AEC to Isotopes, also discussing safeguards inspection described above
A/262 – 70-58	6/11/69 – Martin to AEC, regarding the request for release for public use of a facility formerly used for nuclear activities by Martin Marietta Corp
A/263 – 70-58	6/17/69 – Isotopes to AEC, regarding the abandonment of a facility formerly used for nuclear activities. States that Isotopes Nuclear Systems Division recently completed decontamination of the Martin Marietta Corp Radiochemistry Laboratory (KJ)
A/264 – 70-58	6/20/69 – AEC to Isotopes, AEC thanks Isotopes for their letter of June 5, 1969 in response to our April 22, 1969 letter, corrective actions will be reviewed during the next safeguards inspection
A/265 – 70-58	6/21/69: Hand written document pertaining to Martin company containers and certain drop test results
A/266 – 70-58	7/7/69 – AEC to Isotopes, AEC informs Isotopes that the application submitted for the renewal of SNM-53 was still insufficient and requested a resubmittal
A/267 – 70-58	7/7/69 – AEC to Martin, regarding the release for public use of a facility (KJ building) formerly used for nuclear activities by Martin Marietta Corporation and Isotopes Inc
A/268 – 70-58	7/8/69 – AEC to Isotopes with a notification of intended action regarding application dated 6/30/69, no action by that division is required
A/269 – 70-58	7/14/69 – Isotopes acknowledging P. Knapp they received the letter of 6/17/69 stating building KJ is no longer needed for radioisotope operations under AEC byproduct material license 19-01398-33, survey reports indicate that there is no need to maintain building KJ as a restricted area nor to require a license of subsequent possessors of the building
A/270 – 70-58	7/15/69 – AEC to Isotopes with a notification of intended action regarding application dated 7/7/69, no activity needed by that division
A/271 – 70-58	7/25/69 – AEC to Isotopes, AEC confirms the receipt of further information requested for the renewal of SNM-53 and will now review
A/272 – 70-58	8/15/69 – Isotopes to AEC, regarding Isotopes' Nuclear Systems Division moving to new facilities, Isotopes states they will vacate Middle River facilities by 9/30/69
A/273 – 70-58	8/15/69 – Isotopes to AEC, Isotopes requests amendment to SNM-53 to extend the expiration date, allow them to possess material at their new location in Timonium, MD, and possession of SNM
A/274 – 70-58	9/4/69 – AEC to Isotopes with a notification of intended action regarding application dated 8/15/69, no action required by that division
A/275 – 70-58	9/23/69 – AEC to Isotopes, AEC encloses the SNM license SNM-1150 to be used at the facility in Timonium, MD

A/276 – 70-58	1/29/70 – AEC to Martin, describes a phone call from Martin personnel telling AEC they have decided to apply for a license to receive the contaminated Baltimore facility back from Isotopes Inc and for authority to decontaminate the premises
A/277 – 70-58	2/3/70 – AEC to Martin, describing a phone conversation on 1/29/70 about licensing requirements
A/278 – 70-58	2/20/70 – AEC internal, discussing replies to letters back and forth between Martin and AEC, discusses how no further replies are necessary
A/279 – 70-58	4/24/70 – Martin to AEC, Martin encloses the completed application and work procedure for a license to permit the decontamination of the nuclear laboratories in building "D" if Martin Marietta corporation facilities, Middle River, MD
A/280 – 70-58	5/22/70 – AEC to Martin, AEC encloses Material License SNM-1192 and a copy of their guidelines for decontamination of facilities and equipment
A/281 –70-58	7/8/81 – Department of Health and Mental Hygiene to US Nuclear Regulatory Commission, in reference to a letter of 8/7/80 regarding formerly used sites in connection with source material licenses for and/ or operations at these sites
A/282 – 70-58	7/29/81 – US NRC internal, describes Maryland's response to 7/7/81 inquiry concerning Martin Marietta's formerly licensed site, with responses concerning Tennessee, New York and Kansas sites
A/283 – 70-58	9/9/81 – Department of Health and Mental Hygiene to US NRC, Describes a reply to the letter from 7/15/81 regarding formerly licensed sites in MD. DoHMH obtained additional information that building "D" was demolished and now is a plot of grass, the site was decontaminated to acceptable levels at the time the building was demolished to meet the requirements of the NRC
A/284 – 70-58	6/1/82 – Martin to USNRC, Martin encloses a copy of the "Comprehensive Radioactive Survey Report for the Release of the Decontaminated Premises for Unrestricted Use" prepared in accordance with USAEC material license SNM-1192 issued to Martin for the decontamination of nuclear laboratories at Baltimore, MD.
A/285 – 70-58	8/2/82 – USNRC Region I Inquiry for Martin Marietta Corporation Middle River Facilities in Middle River, MD.
A/286 – 70-58	8/19/82 – USNRC internal, describes that between March 5 and June 15 of 1982 Region I conducted an inquiry of the Martin facility, determines the facility meets current criteria for unrestricted use
A/287 – 70-58	1/23/95 – ORNL Sites Summary. Explains that License STB-00187 authorized the possession and use of large amounts of thorium alloy in Building D at Middle River, MD from 1961 to 1964. The report indicates that some contamination remained in drains and on surfaces, the building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on 11/3/94 indicate that the site is suitable for unrestricted use.
A/288 – 70-58	1/23/95 – ORNL Sites Summary. Explains license SNM-00011 authorized research and development work with U-235 in Building D at Middle River. The report of a final survey of Building D in 1970 indicates that some contamination remained in drains and on surfaces, the building was demolished following that survey. In 1982 Region I staff concluded that the site met the current criteria for release for unrestricted use. The results of a NRC site visit and survey on 11/3/94 indicate that the site is suitable for unrestricted use.

A/289 – 70-58	1/23/95 – USNRC Region I inspection summary of Middle River Facility and Martin State Airport , inspection conducted 11/3/94, results conclude that no radiation levels above background were detected and no indication of contamination was found in any of the buildings and these facilities are suitable for unrestricted use.

The propulsion Systems Department is at work on several classified government projects, including its contribution to a study contract for the National Aeronautics and Space Agency in the RIFT (Reactor in Flight Test) program, under which plans are being formulated for the flight testing of the first nuclear rocket engine.

U.S. NUCLEAR REGULATORY COMMISSION

Report No. 94-001

Docket Nos. None, None, 070-00014, 070-00058, 070-00908, 070-00932, 070-00058, 040-03296

License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, STB-00187

Licensee: Martin-Marietta Aero & Naval Systems
103 Chesapeake Park Plaza
Baltimore, MD 21220

Facility Name: Middle River Facility and Martin State Airport

Inspection at: 2323 Eastern Blvd
Baltimore, MD
and
701 Wilson Point Road
Baltimore, MD

Inspection Conducted: November 3, 1994

Inspector: Stephen W. Holmes, Radiation Specialist — 01/23/95 date

Approved by: John D. Kinneman, Chief
Site Decommissioning Section — 1/23/95 date

Inspection Summary: Closeout Verification Inspection No. 94-001.

Areas Inspected: Announced, inspection and survey of Buildings C and D at the Martin-Marietta Middle River facility and Buildings KJ and KC at the Martin State Airport.

Results: No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from the present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

Joseph Alcarese, Esq.
Joanne Brooks, Environmental Specialist, Environmental Program Manager, Maryland Aviation Administration
Richard Brisson, former Acting Program Administrator, Maryland Dept. of the Environment, Radiological Health Program and former Martin-Marietta/Isotopes,Inc. employee
Thomas Flynn, Jr., Engineer, Raytheon (formally Ebasco Services, Inc.)
* Ray Manley, Inspector, Maryland Department of the Environment
Glen Peregoy, Engineer, Martin State Airport
* Jeffrey G. Smith, Manager Environmental Affairs, Martin Marietta
Jake West, Manager, Martin State Airport

* denotes those present at exit interview

2.0 Background

2.1 General

As part of a program to ensure that facilities where activities authorized by AEC and NRC licenses that have been terminated were suitable for release for unrestricted use as specified in current NRC criteria, the docket files for License Nos. 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, and STB-187 were reviewed. Based on information in the files, the radiological status of four buildings could not be determined with certainty. These are Buildings C, D, on the Martin Marietta Corporation Middle River Facility and KJ (critical facility), and KC (radioisotope laboratory) on the Martin State Airport. Therefore, an onsite inspection was conducted. Prior to the on-site inspection, available records pertaining to the licensing, operation, and decommissioning of the activities in and around these buildings were reviewed by the inspector. Additionally, the inspector contacted two persons who had direct contact with these sites during actual operations or decommissioning: Mr. Thomas A. Flynn, Jr. the Project Manager of the 1965 "dismantling" of the Liquid Fluidized Bed Reactor (LFBR) at Building KC and Mr. Richard Brisson, a former employee of both Martin-Marietta, and Isotopes, Inc. Information obtained from these sources is documented in pertinent sections of this report.

2.2 Building D

Building D was located at the Martin-Marietta's Middle River, Maryland facility which is also called Chesapeake Park. Under License Nos. 19-01398-32, SNM-11, SNM-53, SNM-1192 and STB-187 a wide range of byproduct, source and special nuclear material were used in connection with various research and development activities in addition to work under government contracts. The facility was decontaminated in late 1970 under License No. SNM-1192, the license terminated, and the building subsequently demolished, leaving only the concrete basement floor/pad. An NRC inquiry regarding the site in June 1982 concluded that the site met the then current criteria for unrestricted use (Report Nos. 040-

03296/82-01 and 040-02308/82-011). However, there was no indication that a verification of the licensee's commitment to seal five contaminated drains with concrete was made.

2.3 Building C

Building C, also located at the Middle River site, was to have been used under License No. SNM-849 for operations involving encapsulated Pu-238 in conjunction with SNAP reactors and testing of fuel capsules and radioisotope generators containing Pu-238. This was reported to have occurred in the Environmental Test and Large Vacuum Chamber Laboratories. The building, which was being used as a warehouse at the time of this inspection, is a very large hanger type structure with a corresponding large basement. No records were available regarding the location of the laboratories within the building nor were any records of a termination or confirmatory survey of the facility available. Mr. Brisson stated that, to the best of his knowledge, only environmental and physical testing of the fueled SNAP and other radioisotope generators was performed in Building C and that no unsealed radioisotopes were used there. Additionally, he stated that the laboratories were located in the basement at the south west corner of the building and occupied an area no larger than 100' x 150' or 5 support pillars by 6 support pillars.

2.4 Building KJ

License No. 19-01398-20 was issued to Martin-Marietta for processing of Am-241 and Cm-242 in Building KJ which was designated the Radioisotope Laboratory and is located on the Martin State Airport property referred to as Strawberry Point, on a dirt access road off Strawberry Point Road, 330' S.W. of Building KC. This type of work had been previously performed in Building "D". The license was transferred to Isotopes, Inc. without a change in license number or location of work. In late 1969, Isotopes, Inc. requested termination of the license, simply stating that all radioactive material possessed under the license had been disposed of in accordance with 10 CFR 20 by transfer to a company authorized to receive the licensed material. The AEC terminated the license without comment. No record of a termination or confirmatory survey is in the docket file. Mr. Brisson stated that production processing did not occur in Building KJ and that only small source (μCi amounts of Am-241, no Cm-242) developmental operations to verify the chemistry were performed in the building. He and one other member of the Isotopes, Inc. staff performed the final cleanup and survey of the facility, including the removal and disposal of the HEPA filters. According to his memory, the survey demonstrating that the facility was ready for unconditional release was sent to the AEC contracting office on Hudson St., N.Y., N.Y.

2.5 Building KC

Building KC, the Critical Test Facility, was located 330' North East of Building KJ. The Martin-Marietta LFBR was situated in one of the building's three "test cells". Under License No. SNM-53 completed MH-1A fuel assemblies were stored in the test cells. License No. SNM-907 was issued to Ebasco Services, Inc. in 1965 for dismantling and removing the LFBR. The license included a provision to provide records of a post removal survey to the AEC's New York Operations Office and to Martin Marietta. Although a pre-dismantling survey was performed, no records of the required post removal survey could be found in the docket file. However, it was noted in the file that the LFBR never achieved criticality. Mr. Flynn stated that meticulous care was taken during the dismantling to prevent the spread of any contamination. Further, he stated that an AEC Inspector/Health Physicist from the New York Field Office/Laboratory was on site, oversaw the final survey, and signed the final report that asserted the dismantling of the LFBR had not added to or increased the contamination from the levels measured before the operation. Mr. Brisson confirmed that Ebasco's work produced no contamination throughout the rest of the building. Mr. Brisson also stated that his group decontaminated the underground LFBR water dump/holding tank by sandblasting the insides and disposing of the residue at a licensed burial site.

3.0 Instruments Used in Survey

During the survey three instruments were used, an Eberline PRM-6 with a 1" scintillator probe and a Ludlum Micro R meter Model 19 were used by the state inspector while a Ludlum Micro R meter Model 12 was used by the NRC inspector. The meters were calibrated, functional, and would detect gamma emitters of low energy and with good sensitivity. Based on the isotopes in question, these instrument were appropriate for this survey.

4.0 Survey Results

4.1 General

On November 3, 1994 surveys of each building/site were performed jointly by the NRC and State of Maryland inspectors. The inspectors surveyed each facility thoroughly and kept each other informed as to the results. The surveys were performed with the Micro R meters held at 0.5 meters above the surface with a forward movement of about 1.0 meters per second. In addition to Mr. Smith, who accompanied the inspectors to each site, Mr. Peregoy was present during the surveys of Buildings KC and KJ on the Martin State Airport property.

4.2 Building D

The Building D site was being use to store trailers under contract with the Army. The site consisted of a large concrete pad, the leftover basement floor of the old building. The pad had numerous cracks, holes, and was very weathered after two decades of exposure to the elements.

The inspectors surveyed the concrete pad along parallel lines 5 meters apart, paying attention to drains, clean-outs, and holes in the pad. In addition to measurements taken at drains and clean-outs, surface contact readings were also taken at approximately 10 meter intervals. Numerous sealed/filled in drains/clean-outs/penetrations/holes in the pad were located. Although a few places were found where a hole in the pad had been filled with concrete, it could not be determined if these were any of the drains referred to in the closeout survey. Martin Marietta staff stated that the rubble from the demolition of the building was the responsibility of the contractor and was removed and believed to have been disposed of in a landfill. No detectable radiation levels above background (5μR/hr) were found. No development or other use of the site is planned by Martin Marietta.

4.3 Building C

The Building C area where the old Environmental Test and Large Vacuum Chamber Laboratories were located is now warehouse space and a large empty room. With the exception of the support columns, no original walls, floors, ceiling, or ducts are left. The inspectors surveyed the area along parallel lines at 5 meter intervals with surface contact measurements every 5 meters and at drains and original concrete support columns. No radiation levels above background (5μR/hr) were detected.

4.4 Building KC

Building KC is at the end of a dirt access road off Strawberry Point road just east of the eastern most taxi way. The property was purchased in toto by the State of Maryland in 1975 and although the building was used in the past for storage, it has been abandoned and left open to the elements for the past ten to fifteen years. The site was completely abandoned, overgrown, exposed to the elements (of the three "test cells" only the one where the LFBR had been housed still had it's outer doors). The inspectors performed a walk-through survey of all three cells, the entrance way and connecting halls. Surface contact measurements were performed randomly throughout the building. The office/control room area was not entered due to the cluttered condition of and the layer of asbestos ceiling tiles covering the floor. No radiation levels above background were detected. Although an attempt was made to locate the underground dump/hold-up tank described by Mr. Brisson, the inspectors were unable to locate the tank or any indication that it had been removed. Based on discussion with Martin-Marietta and Martin State Airport personnel, it is believed that the tank was abandoned in place after the decontamination described in Section 2.5. The planning representative of Maryland Aviation stated that the building had been scheduled for demolition after remediation of the asbestos, but the plans were delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

4.5 Building KJ

Building KJ is 300' S.W. of building KC along the dirt access road. The

site was also completely abandoned, overgrown, exposed to the elements. The doors into the laboratory and, mechanical equipment room and office were ajar leaving the interior open to the outside. The inside was littered with "junk", leaves, bird and animal droppings, and dirt. A fair number of 100 lb. bags of "solidified" lime were present, as the building had been use for storage by the State of Maryland in the past. Rusted laboratory furniture and discarded fire extinguishers also littered the floor. The stainless steel ventilation duct-work and the laboratory hoods were still present less the duct-work section that had contained the HEPA filters. The inspectors surveyed the remains as well as possible given the state of the building. No radiation levels above background were detected. The planning representative of Maryland Aviation stated that the building, just like Building KC, had been scheduled for demolition after remediation of the asbestos, but the demolition was delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

5.0 Conclusions

No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

6.0 Exit Interview

The inspector met with the Martin-Marietta and Maryland Department of the Environment representatives listed in Section 1.0 of this report and discussed the scope and findings of this inspection. They acknowledged the inspection findings and the statements documented in this report. Messrs. Flynn and Brisson were contacted by telephone and also confirmed their statements in this report.

Inspection Summary: Closeout Verification Inspection No. 94-001.

Areas Inspected: Announced, inspection and survey of Buildings C and D at the Martin-Marietta Middle River facility and Buildings KJ and KC at the Martin State Airport.

Resul ts: No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from the present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

2.0 Background

2.1 General

As part of a program to ensure that facilities where activities authorized by AEC and NRC licenses that have been terminated were suitable for release for unrestricted use as specified in current NRC criteria, the docket files **for License Nos. 19-01398-20, 19- 01398-32, SNM-11, SNM-53, SNM-849, SNM-907, SNM-1192, and STB-187 were reviewed.** Based on information in the files, the radiological status of four buildings could not be determined with certainty. These are Buildings C, D, on the Martin Marietta Corporation Middle River Facility and KJ (critical facility), and KC (radioisotope laboratory) on the Martin State Airport. Therefore, an onsite inspection was conducted. Prior to the on- site inspection, **available records pertaining to** the licensing, operation, and decommissioning of the activities in and around these buildings were reviewed by the inspector. Additionally, the inspector contacted two persons who had direct contact with these sites during actual operations or decommissioning: Mr. Thomas A. Flynn, Jr. the Project Manager of the 1965 "dismantling" of the Liquid Fluidized Bed Reactor (LFBR) at Building KC and Mr. Richard Brisson, a former employee of both Martin-Marietta, and Isotopes, Inc. Information obtained from these sources is documented in pertinent sections of this report.

Building D

byproduct, source and with various research

Building D was located at the Martin-Marietta's Middle River, Maryland facility which is also called Chesapeake Park. Under License Nos. 19-01398-32, SNM-11, SNM-53, SNM-1192 and STB-187 a wide range of special nuclear material were used in connection and development activities in addition to work under government contracts. The facility was decontaminated in late 1970 under License No. SNM-1192. the license terminated. :_-~d the building subsequently demolished, leaving only the concrete basement floor/pad. An NRC inquiry regarding the site in June

1982 concluded that the site met the then current criteria for unrestricted use (Report Nos. 040

03296/82-01 and 040-02308/82-011). However, there was no indication that a verification of the licensee's commitment to seal five contaminated drains with concrete was made.

Building C

Building C, also located at the Middle River site, was to have been used under License No. SNM-849 for operations involving encapsulated Pu-2138 in conjunction with SNAP reactors and testing of fuel capsules and radioisotope generators containing Pu-238. This was reported to have occurred in the Environmental Test and Large Vacuum Chamber Laboratories The building, which was being used as a warehouse at the time of this inspection, is a very large hanger type structure with a corresponding large basement. No records were available regarding the location of the laboratories within the building nor were any records of a termination or confirmatory survey of the facility available. Mr. Brisson stated that, to the best of his knowledge, only environmental and physical testing of the fueled SNAP and other radioisotope generators was performed in Building C and that no unsealed radioisotopes were used there. Additionally, he stated that the laboratories were located in the basement at the south west corner of the building and occupied an area no larger than 100' x 150' or 5 support pillars by 6 support pillars.

2.4 Building KJ

License **No. 19-01398-20 was** issued to Martin-Marietta for processing of Am-241 and Cm-242 in Building KJ which was designated the Radioisotope Laboratory and is located on the Martin State Airport property referred to as Strawberry Point, on a dirt access road off Strawberry Point Road, 330' S.W. of Building KC. This type of work had been previously performed in Building "D". The license was transferred to Isotopes, Inc. without a change in license number or location of work. In late 1969, Isotopes, Inc. requested termination of the license, simply stating that all radioactive material possessed under the license had been disposed of in accordance with 10 CFR 20 by transfer to a company authorized to receive the licensed material. The AEC terminated the license without comment. No record of a termination or confirmatory survey is in the docket file. Mr. Brisson stated that production processing did not occur in Building KJ and that only small source (uCi amounts of Am-241, no Cm242) developmental operations to verify the chemistry were performed in the building. He and one other member of the Isotopes, Inc. staff performed the final cleanup and survey of the facility, including the removal and disposal of the HEPA filters. According to his memory, the survey demonstrating that the facility was ready for unconditional release was sent to the AEC contracting office on Hudson St., N.Y.

N. Y.

2.5 Building KC

Building KC, the Critical Test Facility, was located 330' North East of Building KJ. The Martin-Marietta LFBR was situated in one of the building's three "test cells". Under License No. SNM- 53 completed MH-1A fuel assemblies were stored in the test cells. License No. SNM-907 was issued to Ebasco Services, Inc. in 1965 for dismantling and removing the LFBR. The license included a provision to provide records of a post removal survey to the AEC's New York Operations Office and to Martin Marietta. Although a pre-dismantling survey was performed, no records of the required post removal survey could be found in the docket file. However, it was noted in the file that the LFBR never achieved criticality. Mr. Flynn stated that meticulous care was taken during the dismantling to prevent the spread of any contamination. Further, he stated that an AEC Inspector/Health Physicist from the New York Field Office/Laboratory was on site, oversaw the final survey, and signed the final report that asserted the dismantling of the LFBR had not added to or increased the contamination from the levels measured before the operation. Mr. Brisson confirmed that Ebasco's work produced no contamination throughout the rest of the building. Mr. Brisson also stated that his group decontaminated the underground LFBR water dump/holding tank by sandblasting the insides and disposing of the residue at a licensed burial site.

3.0 Instruments Used in Survey

During the survey three instruments were used, an Eberline PRM-6 with a 1" scintillator probe and a Ludlum Micro R meter Model 19 were used by the state inspector while a Ludlum Micro R meter Model 12 was used by the NRC inspector. The meters were calibrated, functional, and would detect gamma emitters of low energy and with good sensitivity. Based on the isotopes in question, these instrument were appropriate for this survey.

4.0

4.1 General

Survey
Results

On November 3, 1994 surveys of each building/site were performed jointly by the NRC and State of Maryland inspectors. The inspectors surveyed each facility thoroughly and kept each other informed as to the results. The surveys were performed with the Micro R meters held at 0.5 meters above the surface with a forward movement of about 1.0 meters per second. In addition to Mr. Smith, who accompanied the inspectors to each site. Mr. Peregoy was present during the surveys of Buildings KC and KJ on the Martin State Airport property.

4.2 Building D

The Building D site was being use to store trailers contract

the Army. site consi sted of a I arge concrete pad, the leftover

basement floor of the old building. The pad had numerous cracks, holes, and was very weathered after two decades of exposure to the elements.

The inspectors surveyed the concrete pad along parallel lines 5 meters apart, paying attention to drains, clean-outs, and holes in the pad. In addition to measurements taken at drains and clean-outs, surface contact readings were also taken at approximately 10 meter intervals. Numerous sealed/filled in drains/clean-outs/penetrations/holes in the pad were located. Although a few places were found where a hole in the pad had been filled with concrete, it could not be determined if these were any of the drains referred to in the closeout survey. Martin Marietta staff stated that the rubble from the demolition of the building was the responsibility of the contractor and was removed and believed to have been disposed of in a landfill. No detectable radiation levels above background (5uR/hr) were found. No development or other use of the site is planned by Martin Marietta.

4.3 Building C

The Building C area where the old Environmental Test and Large Vacuum Chamber Laboratories were located is now warehouse space and a large empty room. With the exception of the support columns, no original walls, floors, ceiling, or ducts are left. The inspectors surveyed the area along parallel lines at 5 meter intervals with surface contact measurements every 5 meters and at drains and original concrete support columns. No radiation levels above background (5uR/hr) were detected.

4.4 Building KC

Building KC is at the end of a dirt access road off Strawberry Point road just east of the eastern most taxi way. The property was purchased in toto by the State of Maryland in 1975 and although the building was used in the past for storage, it has been abandoned and left open to the elements for the past ten to fifteen years. The site was completely abandoned, overgrown, exposed to the elements (of the three "test cells" only the one where the LFBR had been housed still had it's outer doors). The inspectors performed a walk-through survey of all three cells, the entrance way and connecting halls. Surface contact measurements were performed randomly throughout the building. The office/control room area was not entered due to the cluttered condition of and the layer of asbestos ceiling tiles covering the floor. No radiation levels above background were detected. Although an attempt was made to locate the underground dump/hold-up tank described by Mr. Brisson, the inspectors were unable to locate the tank or any indication that it had been removed. Based on discussion with Martin-Marietta and Martin State Airport personnel, it is believed that the tank was abandoned in place after the decontamination described in Section 2.5. The planning representative of Maryland Aviation stated that the building had been scheduled for demolition after remediation of the asbestos, but the plans were delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

4.5 Building KJ

Building KJ is 300' S.W. of building KC along the dirt access road. The

site was also completely abandoned, overgrown, exposed to the elements. The doors into the laboratory and, mechanical equipment room and office were ajar leaving the interior open to the outside. The inside was littered with "junk", leaves, bird and animal droppings, and dirt. A fair number of 100 lb. bags of "solidified" lime were present, as the building had been use for storage by the State of Maryland in the past. Rusted laboratory furniture and discarded fire extinguishers also littered the floor. The stainless steel ventilation duct-work and the laboratory hoods were still present less the duct- work section that had contained the HEPA filters. The inspectors surveyed the remains as well as possible given the state of the building. No radiation levels above background were detected. The planning representative of Maryland Aviation stated that the building, just like Building KC, had been scheduled for demolition after remediation of the asbestos, but the demolition was delayed due to finances. He stated that the building would be razed and the rubble disposed of as normal waste.

5.0 Conclusions

No radiation levels above background were detected and no indication of contamination was found in any of the buildings. Based on information obtained from NRC files, Martin-Marietta and Raytheon (formerly EBASCO) employees and former employees, statements from present owners, and the inspectors' surveys, these facilities are suitable for unrestricted use.

6.0 Exit Interview

The inspector met with the Martin-Marietta and Maryland Department of the Environment representatives listed in Section 1.0 of this report and discussed the scope and findings of this inspection. They acknowledged the inspection findings and the statements documented in this report. Messrs. Flynn and Brisson were contacted by telephone and also confirmed their statements in this report.

SUBJECT: NRC REGION I INSPECTION NO. 94-
001

Dear Ms. Brooks:

Docket Nos. None None 070- 00014 070- 00058 070- 00908 070- 00932 070- 00058
040- 03296

As Stephen Holmes of my staff discussed **with you by telephone on October** 20, 1994, the Nuclear Regulatory Commission (NRC) has been reviewing records to ensure that facilities, where activities were authorized by Atomic Energy Commission (AEC) and NRC licenses that have been terminated, are suitable for release for unrestricted use in accordance with current NRC guidelines. As you may be aware, the NRC and its predecessor, the AEC, issue licenses that authorize the use of various radioactive materials.

A contractor for the NRC, Oak Ridge National Laboratory (ORNL), initially reviewed each terminated license file and scored it according to a system designed to identify facilities that require additional review by the NRC staff. In general, files that indicate that radioactive material may have been used at particular facilities, but which do not include adequate final survey records for those facilities, are identified for additional review. The review by ORNL identified License Nos. 19-01398-20, 19-01398-32, SNM- 11, SNM-53, SNM-849, SNM-907, SNM-1192 and STB-187 as files describing sites that require additional review. These licenses were issued to Martin-Marietta, Isotopes, Inc., and Ebasco and authorized activities at the Martin-Marietta Middle River Facility and the Martin State Airport. The Region I staff reviewed these files and determined that additional action was necessary since the information in the files did not provide sufficient detail to conclude that Buildings C, D, KJ and KC meet current guidelines for release for unrestricted use.

Gentlemen:

Pursuant to the Atomic Energy Act of 1954 and Section 40.21 of the Code of Federal Regulations, Title 10 - Atomic Energy, Chapter 1, Part 40 - Control of Source Material, you are hereby licensed to receive possession of and title to two hundred (200) pounds of magnesium-thorium alloys, one gram of uranium metal and two grams of thorium metal for use, during the term of this license, in connection with your work under government contracts.

You are further licensed to transfer and deliver possession of and title to refined source material to any person licensed by the Atomic Energy Commission, within the limits of his license.

As a condition of this license, you are required to maintain records of your inventories, receipts and transfers of refined source material.

This license is subject to all the provisions of the Atomic Energy Act of 1954 now or hereafter in effect and to all valid rules and regulations of the U. S. Atomic Energy Commission, including 10 CFR 20, "Standards For Protection Against Radiation."

Neither this license nor any right under this license shall be assigned or otherwise transferred in violation of the provisions of the Atomic Energy Act of 1954.

This license shall expire June 1, 1958.

APPLICATION FOR GENERAL LICENSE TO RECEIVE, POSSESS, USE AND TRANSFER SPECIAL NUCLEAR MATERIAL (PART 70, CFR 10)

I. The Martin Company is engaged in design, research, development and construction of nuclear reactors and nuclear components at its Middle River Plant near Baltimore, Maryland. For the purpose of development and fabrication of reactor fuel elements, a Nuclear Materials Laboratory and a Pilot Manufacturing Plant have been constructed in the basement of "D" Building at Plant I. A critical experiment facility for zero power testing of proto-type reactor cores is in the final stage of completion. This facility is located near the Martin airport some two thousand feet southeast of Plant I.

Research and development work on fuel elements is conducted under Special Nuclear Material License No. 11, as amended, in accordance with procedures described in the Company's applications of May 22, 1957 and September 19, 1957. The most recent revision of this license permits special operations involving fully clad fuel elements to be performed in the pilot manufacturing plant and in other buildings at Plant I in addition to the laboratory areas.

Initial operation of the Pilot Manufacturing Plant involves fabrication of stainless steel tubular elements containing highly enriched UO_2, for a proto-type MPR core to be tested to zero power for the Atomic Energy Commission under Contract AT (30-3)-277. Government-owned fuel has been handled through Accountability Station MND, which was authorized by the Schenectady Operations Office after approval of the Martin Nuclear Division's procedures regarding criticality control, accountability, health and safety, and security.

In addition to MPR type tubular elements, The Martin Company plans to fabricate other fuel element types in the Pilot Manufacturing Plant. Certain special operations will be performed in other buildings at Plant I. Some of the work to be undertaken will be on a commercial basis and therefore must be done under a Special Nuclear Material License issued by the Commission. In this connection, note is made that the Commission issued SNM License 53 to The Martin Company on November 26, 1956 permitting receipt and possession of fifty (50) kilograms of UO_2 enriched to over 90% in the isotope U235.

Several types of fuel elements including rods, tubes and plates will be manufactured. These elements will utilize uranium metal or uranium dioxide in a fuel marrow clad with such materials as stainless steel, aluminum alloys and zirconium alloys.

DOCKETED USAEC Division of Civilian Application DEC 13 1957 RVF Docket Officer

In view of these varied contemplated activities, The Martin Company pursuant to Part 70, CFR 10 hereby applies for a general license to receive, possess and use up to five hundred kilograms of contained U235 in special nuclear materials at its Middle River facilities, including uses in the Critical Experiment Facility other than activities licensed under Part 50, CFR 10. Application is made for a license extending for three years from date of issuance. The experience gained by the Nuclear Division during the past three years in safe handling of nuclear materials is reflected in the general procedures outlined in this application in sections which follow.

II. Information required pursuant to Section 70.22, Title 10, Chapter 1, CFR:

(1) Applicant is The Martin Company, Baltimore 3, Maryland incorporated in the State of Maryland and having its principal plant and place of business at Middle River, Maryland.

Principal officers are:

G. M. Bunker, President, The Martin Company, Baltimore 3, Maryland - USA

W. B. Bergen, Executive Vice President, The Martin Company, Baltimore 3, Maryland - USA

W. L. Lucas, Secretary and Treasurer, The Martin Company, Baltimore 3, Maryland - USA

The Martin Company is not owned, controlled, or dominated by an alien, a foreign corporation, or foreign government. The applicant is the real party in interest and is not making this application as an agent for any undisclosed principal.

(2) Activities:

Attached for reference are plans of the nuclear facilities at the Martin Middle River plant showing work areas and quantities of special nuclear material (in terms of contained isotope U235) permitted in each work area:

Plate 1 - Plan of Engineering Materials Laboratory
Plate 2 - Plan of Pilot Manufacturing Plant
Plate 3 - Plan of Critical Experiment Facility located near Martin airport.

General procedures in connection with activities contemplated are:

(a) Receiving -

SNM will be received at Gate 5 of Plant I by the Accountability Representative. After monitoring by Health Physics Services for radiation hazards, shipments will be conveyed to Vault Annex Room, (Work Area IB) or Vault, (Work Area IA) for unpacking and weighing of special nuclear material.

(b) Storage -

The storage vault is a fully enclosed room, 22'8" by 13'9" by 11'0" high. It is designed to hold up to 600 kilograms of enriched uranium in powders, foils, elements or ingots stored in birdcage devices approximately 12" x 12" to 17" x 17" in cross-section. Walls, ceiling, and floor are constructed of a minimum of 9 inches of reinforced concrete. Sole entrance to the vault is through a $1\frac{1}{2}$" steel door equipped with a three-way combination lock. There are no water or service piping or drains within the vault.

Materials will be stored in separate containers containing quantities which are less than the theoretical critical masses calculated for optimum conditions with respect to geometry of container, moderators, and reflector according to the calculating procedures outlined in the Martin Criticality Precautions Manual, MND-1063 (Appendix A) and its reference "A Guide to the Calculation of Criticality Limits for Enriched Uranium" by Dr. Chernick. Each container will be at least 12" x 12" in cross-section with a length about 12" longer than the material to be held. Containers and birdcages will vary in design according to the form of the material. For example:

Uranium dioxide powders will be stored in metal bottles of approximately 150 cubic centimeters capacity. No more than 600 grams of uranium dioxide enriched to over 90% in the isotope U235 or more than 550 grams of contained isotope U235 will be stored in each metal bottle. One and only one bottle will be suspended inside a cubical "birdcage" type structure of welded metal construction having dimensions of 16 5/8" x 16 5/8" x 21 3/8".

Uranium metal foil will be stored in birdcages 12" x 12" x 34" with bundles of foil each containing no more than 1000 grams of U235 held roughly in the center by inserts.

Fuel elements, tubular or plate, will be held in cradles in storage devices or similar dimensions (12" x 12" x 30-40"). Each cradle will hold a prescribed number of tubes or plates, the total U235 content of which will be within the allowable limits established for the particular form of material involved.

Solid scrap will be stored in metal boxes 9 1/2" x 11 3/4" x 26", each held in a birdcage 12" by 12" x 40" long.

Insofar as it is practical, all birdcages will be placed in rows along the walls of the vault to permit easy access. The lowest rows will be placed on platforms about 17 inches above the floor to prevent accidental contact with water. Even if flooding occurred above the height of 22" required to reach any special nuclear material, no hazard would exist since (1) all materials will be in latched birdcages in amounts less than the theoretical critical limits and (2) powders will be in water-tight metallic containers within the birdcages.

All material will be stored during non-work hours either in the vault or in locked repository safes in the manufacturing area.

When special nuclear material must be taken from the nuclear facilities to other areas within the Martin plant, it will always be in the custody of a "Q" cleared accountability designee.

(c) Forms of material -

Forms with corresponding allowable limits in contained U235 have been established as shown on the following two pages.

(d) Work Areas and Criticality Control -

Reference is made to Plates 1, 2 and 3 and to the Martin Criticality Precautions Manual, MND-1063, filed with the AEC, April 22, 1957. A revised copy of this manual is attached as Appendix A. The manufacturing area and the critical experiment area have been divided into Work Areas for purposes of control of criticality. The laboratory except for a few designated work areas is considered to be one integral work area. Limits (in terms of U235) are shown on the plates for the various

FORM	ENRICHMENT OF URANIUM IN ISOTOPE U235	TYPE OF MATERIAL	ALLOWABLE LIMIT IN ANY WORK AREA (grams of contained U235)
Ia	all enrichments	UO_2 powder, density when loose approx. 5 gr/cc	800 grams
Ib	all enrichments	UO_2 powder, pressed and sintered shapes density approx. 10 gr/cc	800 grams
Ic	0.72% to 20.0%	UO_2 and ThO_2, powder and sintered shapes	* grams
IIa	highly enriched	UO_2 and stainless steel mixture, density approx. 8.4 gr/cc	1600 grams
IIb	highly enriched	Sintered cermet of UO_2 and stainless steel density approx. 8.4 gr/cc	1850 grams
III	all enrichments	Uranium in aqueous solution	2 grams/liter (1)
IV	highly enriched	Stainless steel clad tubes, with Form IIb as fuel marrow	2000 grams
V	over 20.0%	Stainless steel clad plates with uranium metal as fuel marrow	1600 grams
VIa	over 20.0%	Uranium metal in thin forms; ribbon, foil wire, etc.	500 grams
VIb	over 20.0%	Uranium metal in fine cuttings, dust., etc.	500 grams
VIIa	all enrichments	UO_2 and powdered Al mixture, approx. density 2.5 gr/cc	800 grams
VIIb	all enrichments	Pressed or sintered UO_2 and Al mixture in (VIIa) approx. density 5.0 gr/cc	800 grams

FORM	ENRICHMENT OF URANIUM IN ISOTOPE U235	TYPE OF MATERIAL	ALLOWABLE LIMIT IN ANY WORK AREA (grams of contained U235)
VIIIa	all enrichments	Aluminum alloy clad tubes with Form VIIb as fuel marrow	800 grams
VIIIb	all enrichments	Iron-aluminum alloy clad tubes with Form VIIb as fuel marrow	800 grams
IX	over 20.0%	Uranium metal in buttons, derbies, etc.	10000 grams (2)
X	over 20.0%	Uranium metal in ingots, bars, machined shapes, smallest dimension 70.25 inches	3000 grams
XI	0.72% to 20.0%	Stainless steel clads filled with solid pellets of Form Ib or Ic	2000 grams
XII	over 20.0%	Zirconium, titanium, molybdenum and other "special" alloy-clad plates with uranium metal fuel marrow	grams (3)
XIII	over 20.0%	Uranium-thorium molybdenum alloys	grams (3)

(1) Except when total amount in any one container in all forms is less than 400 grams of U235

(2) Subject to review with regard to minimum dimensions and reflecters

(3) To be determined

forms of SNM (pages 5 and 6) which can be present in each work area at any one time. In the event that several forms are present at one time in a work area, the lowest allowable limit for U235 applies to all materials present.

All transfers between work areas are made by the courier acting as a designee of the Accountability Representative. Enforcement of criticality procedures within work areas is a responsibility of each facility supervisor. Material, under close weighing control, is transported to an "Off-Spot" in work boxes in "carrier" devices. Amounts present in each work area are shown on prominent signs posted by the Accountability Representative.

(e) Manufacturing -

Fabrication of fuel elements will be performed in the pilot shop located in "D" Building.

A few special operations such as brazing of fully clad tubes to end castings will be done in other buildings at Plant I.

Processes, either developed or being developed include:

(1) Fabrication of stainless steel clad plates enclosing uranium metal foil (Form .)

(2) Stainless steel clad tubes enclosing fuel marrow of enriched uranium dioxide-stainless steel cermet (Form IV)

(3) Aluminum and aluminum alloy clad tubes enclosing pressed uranium dioxide-aluminum blended compacts as fuel marrow (Form VIII)

(4) Stainless steel clads filled with solid compacts of uranium dioxide or uranium dioxide and thoria (Form XI)

General descriptions of these processes are outlined in Appendix B with corresponding manufacturing flow charts shown in Appendix C.

(f) Accountability -

The Martin Nuclear Division accountability procedures for strict control of valuable special nuclear materials

apply to both government-furnished SNM and to licensed SNM. Each lot received is assigned a ledger number. All material withdrawn is kept separate from other lots throughout processing. Scrap is kept segregated by contract or project. Thus there is no risk of intermingling materials or several contracts or of different enrichments.

(g) Security -

All facilities are controlled areas with only authorized personnel permitted access. An escort-control pass system is applied to authorized visitors.

Materials are given security protection in accord with the categories outlined in the AEC manual.

(h) Transport to Critical Experiment Facility -

Finished fuel tubes, plates or rods are moved to the facility in "birdcage" transporting devices in a guard-escorted motor vehicle. No more than 800 grams of U235 contained in sealed elements are allowed per "birdcage" device. These birdcage devices are 12" by 12" by 34" and retain in a center position wooden cradles 9 1/2" by 11 3/4" by 23 3/4" which hold the fuel tubes or plates.

(i) Receipt and Storage at Critical Experiment Facility -

After verification by the Accountability Designee of the Facility of the number of tubes or plates delivered the birdcages will be placed in the storage vault. The vault is of similar construction to the vault in the pilot manufacturing plant and has a floor area of 175 square feet. It is accessible only through a 1 1/2" steel door equipped with a three-way combination lock.

(j) Assembly at Critical Experiment Facility -

Tubes or plates are assembled into experimental bundles in Work Area 102, adjacent to the Storage Vault and Test Cells.

Following assembly, the fuel elements (bundles or boxes) will be placed in wooden cradles which are held in the birdcage storage devices. The dimensions of the cradle holding a bundle of thirty-seven (37) MPR tubes are 9 1/2" by 11 3/4" by 23 3/4".

The birdcage devices are then transferred to the storage vault for retention until withdrawal for experimental work authorized by a Class 104 c license.

(k) Shipping procedures -

Shipments of special nuclear material to the Commission or to other licensees will be made as follows:

(1) If the shipment contains no more than 100 grams of U235, the material will be securely packed in a container with resilient material between this container and the outside package. In addition, the parcel will be checked for possible radiation hazards and marked in accordance with ICC regulations.

No more than one package containing up to 100 grams of contained U235 will be transported or delivered to a carrier in any one shipment.

(2) If the shipment contains over 100 grams of U235, the material, depending on its form, will be packed in a container in either one of the Martin "birdcage" devices described in part 2(b) or an equivalent device to be furnished by the shipper. The quantity of U235 in any shipping device will be within the allowable limits for various forms shown on pages 7 and 8 of the manual, MND-1063.

(3) A general license is requested for a period of three years.

(4) Special Nuclear Material will be used in the forms shown in section 2(c). The general categories are:

Uranium dioxide powder; low-enrichment to over 90% enriched in isotope U235
Uranium metal foil, ribbon and wire; low-enrichment to over 90% enriched in isotope U235
Uranium metal ingots, slugs, billets, bars, derbies; all enrichments.

It is not possible to estimate amounts of each type required. However, a total requirement at one time of up to 500 kilograms of contained U235 in SNM is foreseen.

(5) The contemplated requirements for Special Nuclear Material for the last quarter of 1957 and the first quarter of 1958 are shown on the next page.

(6) The Martin Nuclear Division has been engaged in handling special nuclear materials for over two years in research and development of fuel elements. The new laboratory and pilot manufacturing plant have been in operation since June, 1957.

Several new concepts of fuel elements have been developed including the highly-enriched stainless steel clad, UO_2 cermet marrow tubular type. The first core loading of 1700 of these tubes will be completed in November. The technical staff of the Nuclear Division includes some 200 engineers. The manufacturing plant supervisor has had fifteen years of precision shop experience. Health Physics personnel include two senior health physicists each with over 5 years of training at AEC and industrial installations. The Accountability Representative is a public accountant with 10 years experience including 9 months in the handling of nuclear materials.

(7) Equipment and facilities used to protect health and safety -

Storage facilities are described in (2b) and (2i). The manufacturing and laboratory areas are under negative pressure with respect to adjacent working areas of "D" Building. Air flow is from non-contaminated areas to slightly-contaminated areas to more-contaminated areas, with the highest ventilation rates in those rooms or areas where the greatest air-borne contamination is possible.

Exhaust air that may contain appreciable radioactive particulate matter (that is from the hoods or dry boxes) is passed through absolute filters before being released to the atmosphere.

Hoods are used for handling uranium dioxide powders. These hoods, exhausting ducts and glove boxes are equipped with absolute filters. Machining of uranium metal will be done using an oil bath.

A partial list of available instruments and equipment appears as Appendix D.

MATERIAL	ENRICHMENT	QUANTITY ON HAND	4TH QUARTER 1957		1ST QUARTER 1958	
			Receipts	Returns	Receipts	Returns
UO_2 Powder	20%	5 kg	-	3	-	2
UO_2 Powder	over 90%	50 kg	20	25	10	25
Uranium foil	over 90%	0.5 kg	-	-	-	-
Uranium foil	over 90%	-	31	-	-	-
Uranium metal ingot	31%	-			40	40
Uranium metal ingot	over 90%	-			100	100

(8) Health and Safety measures -

Personnel working with radioactive materials (including SNM) or in radiation areas are routinely monitored for external radiation exposure by means of film badges and pocket chambers. Contamination is controlled by surveying likely objects or areas with appropriate detecting instruments or by making filter paper smears (which must be counted with an appropriate detector), recording results, and informing proper supervision. All operating personnel must be constantly alert to contamination possibilities involved in their operations and must continually strive to keep contamination to a minimum. Health Physics takes air samples in areas where airborne contamination is possible (frequency of sampling depends on operation). A tolerance of no more than 5×10^{-11} microcuries per milliliter air is established. If this tolerance is approached all personnel in the area affected are required to wear respirators. Uranium urinalyses and blood tests will be made every three months to check on internal deposition on people assigned to work in these areas.

From receipt of material to shipping or storage, Health Physics will be concerned with contamination and radiation levels from the SNM. External radiation measurements will be made on the received package and recorded. The Accountability Representative will open these packages. Health Physics shall assist in examination for breakage or other damage and subsequent contamination control in case of damage. During weighings of received SNM, Health Physics will make necessary smear checks. Samples to be sent for outside laboratory analysis will be packaged to conform with all pertinent ICC regulations.

Contamination control effectiveness will be checked by Health Physics throughout the operations in the laboratory and in the pilot manufacturing plant.

Protective clothing will be used to reduce personnel contamination.

Disposal of radioactive wastes: There will be no radioactive gaseous effluent from the Martin facilities. The incineration of radioactive combustible materials will be controlled by monitoring the exhaust stack of the incinerator.

Liquid wastes will be stored in polyethelene lined 55 gallon drums until ready for concentration. Batches containing no more than 400 grams of U235 will be reduced nearly to dry salt and these residues will be sent to AEC installations for recovery.

Solid wastes such as incinerator ashes will be mixed with a prepared cement mix before disposal by land or sea burials in accordance with Part 20, CFR 10.

The large volumes of slightly contaminated liquid wastes from the Decontamination Laundry will be held in collecting sumps until filtered, sampled, and counted for radioactivity before discharge to the sanitary sewer. Tap water dilution will be used, if necessary, to reduce the concentration to the levels required by 10 CFR Part 20.

(9) Emergency procedures -

An outline of the procedures to be followed in case of incidents involving nuclear materials is contained in the Criticality Precautions Manual, MND-1063, pages 5 and 5a.

(10) Financial Qualifications -

The Martin Company has done business under its present charter in the State of Maryland for a period of over twenty-five years. Total current assets on December 31, 1956 were $96,000,000 and sales for the year totalled about $360,000,000. The Nuclear Division, headed by a General Manager, is part of the company organization and draws its budgetary support therefrom.

The Martin Company will assume financial responsibility for all special nuclear materials received and will pay to the Commission the presented use charge based on the value of the material until the material is returned to the latter.

A copy of the 1956 Annual Report of the Company is attached as Appendix E.

III. Pursuant to Section 70.32, The Martin Company stipulates that:

(1) Title to all special nuclear material shall at all times be in the United States.

(2) No right to the special nuclear material shall be conferred by the license except as defined by the license.

(3) Neither the license nor any right under the license shall be assigned or otherwise transferred in violation of the provisions of the act.

(4) All special nuclear material shall be subject to the right of recapture or control reserved by section 108 and to all other provisions of the act.

(5) No special nuclear material may be used in any utilization or production facility except in accordance with the provisions of the act.

(6) The licensee shall not use the special nuclear material to construct an atomic weapon or any component of an atomic weapon.

(7) The licensee will hold the United States and the Commission harmless from any damages resulting from the use or possession of special nuclear material by the licensee.

(8) The license shall be subject to, and the licensee shall observe, all applicable rules, regulations, and orders of the Commission.

I certify that the statements made in this application and its attachments are true, complete and correct to the best of my knowledge and belief, and are made in good faith.

THE MARTIN COMPANY

BY: Tibor F. Nagey

My commission expires May 4, 1959.

APPENDIX B

DESCRIPTION OF PROCESSES EITHER DEVELOPED OR BEING DEVELOPED

(1) Stainless steel clad plates enclosing enriched uranium metal foil, Form V.

The process is diagrammed in the flow sheet for Form V, Appendix B. Material is received from processor in clean flat strips of foil, (Form VI) cut to size and enclosed in polyethylene bags. It is stored in birdcage boxes, 12" x 12" x 34" in lots not exceeding 1000 grams of U235 per container. Batches not exceeding 500 grams of contained U235 are withdrawn from storage vault, (Work Area 1a) and transferred by courier to Work Area 10 for assembly between stainless steel plates. Assembly is seam welded, evacuated at a low temperature and a final end seam weld made in Work Area 10. After radiography in Work Area 7, batches of plates will be autoclaved in Work Area 22 to determine porosity reliability.

Destructive and non-destructive testing will be performed on selected plates in Work Area 11.

(2) Stainless steel clad tubes enclosing fuel marrow of enriched uranium dioxide-stainless steel cermet (Form IV).

A description of the process is contained in the confidential manual, MND-1069 which is furnished as a supporting document to this application, (Appendix F). A flow sheet for the process is also included in Appendix C.

(3) Aluminum and aluminum alloy clad tubes enclosing pressed UO_2 -Al blended compacts (Form VIII).

Enriched uranium dioxide is blended with three parts by volume of powdered aluminum in Work Area 2. This blend is compacted to pressed bushings in Work Area 5. The bushings are assembled on a tube of aluminum or aluminum alloy and a second tube is passed over the bushings to complete the assembly. The assembly is swaged and drawn in Work Area 4 and then annealed to complete the metallurgical bonding in Work Area 5. Cleaning of the finished tubes is accomplished in Work Area 9. After radiography in Work Area 7, the assembly is sheared to size (Work Area 4) and the ends seam-welded in Work Area 10. Radiography, non-destructive testing, and porosity testing are done in Work Areas 7, 11 and 20 respectively to complete the tube manufacturing process. Brazing and welding of sealed tubes into bundles will be done in other facilities at Plant I under security and health safety safeguards required.

(4) Stainless steel cladsfilled with pressed compacts of uranium dioxide or uranium dioxide and thoria (Form XI).

Uranium dioxide powder of low enrichment in the isotope U235 is pressed into pellets. These pellets are assembled in stainless steel tubes and the interstices filled with a liquid metal to provide for efficient heat transfer between the fuel and the outside tube.

(An alternate method using ground pellets fitting to close tolerances in the tube may be used.)

The ends of the tubes are welded in Work Area 10 and the completed tubes are radiographed, porosity tested and cleaned.

(Cont'd)

8. Inspection findings
The Baltimore location of the Martin Company is composed of Martin Nuclear Division and Martin, Baltimore. The Nuclear Materials Controls Committee at Martin Company is concerned with all problems involved in the handling of byproduct, source and special nuclear materials. All applications for these materials must be approved by the Controls Committee. Radiation safety instructions and procedures are satisfactory for the work being done with byproduct materials. Facilities for use and handling of the materials on hand, and instrumentation for detection of radiation are adequate. Isotope procurement and survey procedures are sufficient. Leak testing of Sr^{90} sources as required by condition 14 of license -2 and condition 13 of license -9 has not been carried out (Item 15). (Cont'd)

9. Items of noncompliance
20.203 "Caution signs, lables, and signals" -(f)(1) "Containers": labeling of waste containers in waste storage area.
30.3 "License requirements" - Licensee possesses a 1 mc Ra^{170} source not presently covered by a specific license. (Cont'd)

a tool wear study.

19-1098-3 w/amend. #2

Licensee authorized to use 800 curies of Cobalt 60 as sealed source (Brookhaven,
cylindrical) to be used in a shield (Glenn L. Martin drawing MSR-7-0117)
for gamma irradiation research, 1,500 curies of Cobalt 60 as sealed source
(Brookhaven, by 3rd Mod.) and 78 sources of 55 curies each total 4,290 curies of
Cobalt 60 as sealed sources (Ace.) to be used in water shielded facility (Glenn
L. Martin drawings RV-D/Mod) for gamma irradiation research.

19-1098-5

700 milligrams of Promethium 147 as plated copper disc and sealed for roll modification.

19-1098-6 w/amend. #1

25 - 1 curie sources of Cobalt 60, Oak Ridge National Laboratory sealed sources to be
used in ground handling experiments to simulate aircraft reactor system. 25-200
millicuries sources of Cesium 137 as Oak Ridge National Laboratory sealed sources to
be used as gamma source in configuration to obtain a collimated plane source for
instrumentation studies. 7 curies of Beloulum 210 Mound Laboratory or ANL sealed
Be-Be neutron source for the neutron development and foil activation. 1 milli-
curie of Barium 133, 1 millicurie of Nickel 63, 1 millicurie of Potassium 42, 1
millicurie of Silver 85, 10 millicuries of Sodium 22 to be used for the calibration
of instruments.

19-1098-7 w/amend. #1

40 millicuries of Cobalt 60 as NRC sealed source Model No. AMC-3, 1 millicurie of
Cobalt 60 as Tracerlab sealed source Model B-5 for instrument calibration and
testing.

19-1098-8 w/amend. #1

1 millicurie of byproduct material between Atomic No. 3 and 83 inclusive,
t as irradiated structural materials for laboratory testing to determine physical
properties of irradiated materials.

19-1098-9 w/amend. #1

15 millicuries of Cobalt 60 as sealed source, double shielded encapsulated, 100
e of Promethium 147 as sealed source, Standard Model Radium for instrument
calibration and radiation sources for research and development program. 7 curies
of Beryllium-Beryllium 210 as Jordan Electronics, Inc. Sealed Source Model
BE-210, 2 curies of 300 millicuries each - total 600 millicuries of Promethium 90
as Jordan Electronics, Inc. sealed sources Model BE-750 for instrument calibration.

19-1098-2

11. Licensed material shall be used as sealed sources for purposes stated and neutron shall
not be altered, opened or subdivided.

14. Leak tests of the Strontium 90 sources listed above shall be carried out at intervals
of six months and records of the leak test results shall be furnished the Atomic Energy
Commission upon request.

15. Written safety instructions shall be adopted and protection control
procedures shall be furnished to all individuals responsible for handling licensed mat-
erial. The applicant shall indicate the assignment of responsibility for radiological pro-

License No. 19-1396-1

12. This license supersedes authorization numbers 21309 and 21716 issued February 9, 1956 and February 6, 1956.

14. Sealed sources licensed above shall not be opened.

15. Written administrative instructions covering appropriate radiological protection [illegible] of operational procedures and [illegible] responsibility for radiological protection, control and security of the byproduct material shall be supplied individuals using or having responsibility for use of such material.

License No. 19-1396-2

11. Byproduct material to be used only at Martin Company, Engineering Division ANP Project, Baltimore 3, Maryland.

License No. 19-1396-3

This license supersedes license No. 19-1396-2, issued March 29, 1957 to the Glenn L. Martin Company, Baltimore, Maryland.

14. Byproduct material must be encapsulated prior to conveyance by licensee.

15. Sealed sources licensed above shall not be opened.

16. Leak testing of sealed sources containing byproduct material shall be carried out at intervals of 90 days and records of the leak test results shall be furnished the Atomic Energy Commission upon request.

License No. 19-1396-4

17. Leak testing of sealed sources containing beta and/or gamma emitting byproduct material (except those containing iridium 192, tantalum 182, gold 198, and natural cobalt 60 in metallic form) shall be carried out at intervals of not more than six months and records of leak test results shall be furnished the Atomic Energy Commission upon request.

License No. 19-1396-5

13. Sealed sources licensed above shall not be opened.

License No. 19-1396-6

11. Byproduct material to be used by or under the supervision of J.P. Stebbins, D.C. Harvey, [illegible]

License No. 19-1396-7

11. Byproduct material to be used by or under the supervision of Anthony Vivenzo.

12. Sealed sources licensed above shall not be opened.

13. Leak testing of sealed sources containing beta and/or gamma-emitting byproduct material except those containing iridium 192, tantalum 182, gold 198, and plated natural cobalt 60 in metallic form shall be carried out at intervals of six months and records of the leak test results shall be furnished the Atomic Energy Commission upon request.

License No. 19-1396-8

[illegible] Byproduct material licenses issued to the Martin Company, Baltimore, [illegible] facilities at the Martin Company are adequate. The answers to the radiography exhibit [illegible] provided with an appropriate visible or audible alarm [illegible] required by 10 CFR 20.203 (c)(2) - (Item 12). All [illegible] were properly labeled with the [illegible] of several [illegible] to material stored in the [illegible] room (Item 9). Adequate records of [illegible] inventory, [illegible] and [illegible] were maintained. It was noted that the Martin Company has on hand some [illegible] which is not covered by an existing license.

License No. 19-1396-9

Violation [illegible] condition 14 of license 19-1396-8 and condition 13 of license 19-1396-8 requiring leak testing of [illegible] sealed sources.

PART 30 INSPECTION

The Martin Company
Baltimore), Maryland

Date of Inspection: October 22, 1957

Persons Accompanying Inspector:

Dr. W. F. Reindollar, Director, Division of Industrial Hygiene and Air Pollution, Maryland State Department of Health
Mr. Howard Cooney, Division of Industrial Health and Air Pollution, Maryland State Health Department

Persons Contacted:

Mr. C. A. Wendel, In charge of Licensing
Mr. A. J. Stevens, Health Physicist
Mr. Lester Stevens, Accountability Representative
Mr. J. M. Thaler, Nuclear Engineer
Mr. H. D. Wildsmith, Insurance Representative
Mr. H. M. Rosenthal, Supervisor of Reactor Test Unit
Mr. J. T. Hays, Security Officer
Mr. Paul Quinn, Radiation Safety Officer
Mr. Arthur Sheiler, In charge of the Canon facility
Mr. H. O. Banks, Radiological Health, Senior Manufacturing Engineer
Mr. A. E. Lonnert, Senior Nuclear Test Engineer
Mr. J. D. Stubbins, Research Engineer
Miss Harrison, Health Physics Section
Mr. C. H. Krug, Business Manager of Purchasing Department
Mr. A. M. Evans, Nuclear Physicist, Critical Facility

Persons contacted during initial interview at Martin Company when details of the basic organization of the Martin Company were discussed.

Persons contacted by phone only.

12. Organization and Administration

The Baltimore location of The Martin Company (formerly the Glenn L. Martin Co.) is composed of the Nuclear Division and Martin Baltimore. Other than their Baltimore facilities, The Martin Company has additional facilities located in Florida and Colorado.

Mr. Richard Henderson, Office of the General Manager, acts as Chairman of the Nuclear Materials Controls Committee. Other members of the committee are as follows:

Mr. L. B. Stevens, Accountability Representative, Nuclear Division
Mr. C. A. Wendel, Licensing, Nuclear Division
Mr. Paul Quinn, Health Physics Representative, U.S.O., Martin Baltimore
Mr. J. T. Hays, Security Officer, Martin Baltimore
Dr. [illegible] Manufacturing Representative, Nuclear Division
Mr. William Maxwell, Engineering Laboratory, Nuclear Division
Mr. James [illegible], Accountability Engineer, Nuclear Division
Mr. Jesse Darnell, Quality Control, Martin Baltimore

The Nuclear Materials Control Committee is concerned with all problems involved in the handling of by-product, source and special nuclear materials. All applications for these materials must be approved by the Controls Committee.

Mr. Paul Quinn, the Radiological Safety Officer, received experience and training for approximately [illegible] years at Oak Ridge, Tennessee, where he worked under Dr. James Hart as [illegible] Health Physicist on nuclear work. He has an ed[illegible] lectures at

Physics from Ohio State in 1953. He was a research physicist from 1954 - 1957 at Wright Paterson, Ohio where he worked on Van De Graaff accelerators.

Dr. Jack A. Hunter received training and experience in radiation safety for approximately five years at Ohio State University, for one year at NEPA, and for four years at G-E ANP. In Oak Ridge, he worked with approximately 20 curies of Po^{210} for approximately one year.

Mr. H. B. Rosenthal received training and experience in radiation safety at G-E ANPD, he worked with 10 curies of Po^{210}, 1 curie of Co^{60} and 1 curie of Ra^{226}.

19-1398-2 - Mr. Hampton O. Banks, Radio-Chemist, Senior Manufacturing Engineer, received radiation experience and training at Brookhaven National Laboratory for approximately 6 years and at the Missouri School of Mines for approximately 2 years. At Brookhaven, he worked with multi-curie amounts of mixed fission products and kilogram amounts of uranium. Under the supervision of Mr. Banks, one assistant who was trained by Mr. Banks uses radioactive material.

19-1398-3 - Mr. A. W. Kneibler of the gamma facility received experience and training with radioactive materials at the University of Miami from February 53 to June 54 and at the Martin Company from March 1957 to the present time. At the University of Miami he worked with 10 millicurie amounts of cobalt 60 and at the Martin Company he works with approximately 6000 curies of cobalt 60. There are no other persons working with radioactive materials under license -3.

19-1398-4, 6 - Mr. A. H. Lannert, Senior Nuclear Test Engineer was trained at the University of Washington for approximately 2 years and at the Olin-Mathieson Chemical Company for approximately 2 years in the proper handling of radiation and radioactive materials. He worked with approximately 50 millicuries of Sr^{90} - Y^{90} and 1 curie of cobalt 60 at the Olin-Mathieson Company.

Mr. G. J. Rauna, Nuclear Staff Engineer was trained at the University of Rochester for approximately 4 years, at the Brookhaven National Laboratory for approximately 3 months, and at the Oak Ridge National Laboratory for approximately 1 year in all phases involved in the use and handling of radiation and radioactive material. At the University of Rochester he worked with approximately 2 curies of Radium-Beryllium and at the University of Rochester and Oak Ridge National Laboratory he worked with Polonium and Beryllium sources of 6 and 30 curies magnitude. At the Brookhaven National Laboratory he worked with a 1000 curie cobalt 60 source. At the University of Rochester he worked with various amounts of other isotopes up to as much as 6 curies in one year.

No work is presently being done under these licenses.

19-1398-7 - Dr. Phelps, one of the individual users, is no longer with the Martin Company. The qualifications of Mr. A. E. Evans, the other individual user, are listed under license -1.

19-1398-8 - Mr. J. B. Stebbins was trained at Savannah River for approximately 3 years and at Argonne National Laboratory for approximately 8 months in all phases of radiation and the handling of radioactive material. At Savannah River, he worked with quantities up to 5 millicuries of the full fission product spectrum.

Mr. D. G. Harvey received experience and training in the safe handling of radiation and radioactive materials at Massachusetts Institute of Technology for approximately 1 year and at WADC for approximately 3 years.

19-1398-9 - Mr. A. J. Stefanec, Health Physicist, received a B. A. from Western Reserve. He worked as a Health Physicist for the Warshaw Chemical Company from 1948 to 1953. He was employed by National Lead of Ohio as a

[illegible] cadmium lined paraffin block, the door to this cell was interlocked, and the area around the source was enclosed by a rope with a yellow and magenta radiation symbol. The source cells [illegible] must use. At the time of inspection, the source was in storage. When in use, this source is used by the reactor test unit for work in the various cells [illegible].

12-1.9-d - Materials under license -2 and -3 with the exception of 9.5 millicuries of Co[illegible] sources under -2 are used in the radioisotope laboratory and associated facilities which comprise a one story building (see Exhibit 1). A combined counting laboratory approximately 15' by 20' is supplied with a number of Chicago Nuclear-Pie and a number of Chicago G.M. survey meters. Adjacent to the office is a dark room and a tracer laboratory. Both of these are accessible through the office-counting laboratory. The tracer laboratory is equipped with a lathe where irradiated cells under license -2 are used in machining operations. Appropriate portions of the lathe are covered by a hood which provides 2" of lead shielding in the forward direction (directly toward the operator) and 1" of lead on both sides of the lathe. The tracer laboratory also contains a large chemical hood and both the chemical hood and the lathe hood are [illegible] through rotolator filters and separately exhausted to the roof by the ventilating system. In addition, the tracer laboratory is equipped with a double stainless steel sink, sample bench space, and a number of Chicago count rate meters with an end window G.M. detector.

[illegible] the radioisotope laboratory and accessible through the office-counting room is a [illegible] radioactive material. This building is surrounded on all sides by a [illegible] of concrete, with the exception of a portion of one wall where a 5" thick steel door has been provided. The rear wall of this building is underground. [illegible] the radioactive material building is surrounded on two sides by a high fence several feet from the building. This fence restricts [illegible] entering on the roof or approaching too close to the building. A third side of the material joins an adjacent building, and the fourth side shares a common wall with the office-counting laboratory, [illegible] tracer laboratory, [illegible] floor wall, approximately 6' deep and provided with a 2" steel cover, located in the [illegible] radiography exhibit, is used for storage of irradiated structural materials under license -2. The [illegible] also contains [illegible] shielded with lead bricks bearing an [illegible] source, and a lead pig containing a Pi[illegible] source. The public is not equipped with a visible or audible alarm system. Several low level irradiated tool tips were on hand and stored in the tracer laboratory. No [illegible] was on hand at the time of this inspection.

Ir192 [illegible] source, and the Co60 source are used for radiography inside the radiography cubicle. The Ir192 source, used for exterior radiography purposes, is stored [illegible] under license 19-1393-9). Irradiated tool tips are used in tool wear studies. Irradiated structural steel and [illegible] used in [illegible] the physical properties of structural steel and will be used in [illegible].

A few spot checks were made with the [illegible] are stored in air. In the office-counting laboratory, a reading [illegible] of 2 mr/hr at waist height was obtained with an [illegible] source. [illegible] from the fence, a dose rate of [illegible] mr/hr was obtained with the same [illegible]. Banke stated that the dose rate in the [illegible] is well under 6 mr/hr and that all [illegible] from any [illegible] wear film badges. Anyone outside the fence could be [illegible] with no person having reason to remain in this area for any [illegible] length of time.

Frequency of [illegible] not be used [illegible] all in the next week. The [illegible] are used [illegible] making radiographs using the [illegible] as great as [illegible] tool [illegible].

delivered to the material under test in comparatively short periods of time. Mr. Kneibler stated that the source is never removed from the pig, but that the material to be irradiated is placed inside of the pig. Mr. Kneibler also stated that the cover to the pig is kept locked at all times when material is not being removed from or placed into the pig. The lead pig itself is surrounded by the room walls and a metal pipe fence several feet high which prevents the operator from approaching too close to the pig. A radiation reading of 6 mr/hr was obtained at the metal pipe fence and at a distance of approximately 5' from the floor. A reading of 10 mr/hr in the same position was obtained at a height of approximately 7'. Both of these readings were made with the source inside the pig and the cover to the pig in the closed position. It was noted that 3 film badges were placed in various locations around the pig in an attempt to determine accumulated radiation dosages in the vicinity of the pig.

On the floor above and directly over this irradiation facility a film badge is normally placed at floor level and left for a period of one week (7 days, 24 hours per day). Film badge records for 1957 showed that the highest weekly dose to this badge was approximately 800 mr with the weekly dose averaging about 250 to 300 mr. Occupancy in this area would be transient.

The other irradiation facility in the gamma facility room consists of a swimming pool type irradiation set-up. The pool itself is approximately 6 x 6 x 12' deep and is normally filled with water to within 1' of the top of the pool. Sources used for irradiation purposes are stored and used at the bottom of this pool and are not removed from the pool at any time. The sources in the pool facility are arranged in such a fashion that they have approximately 12' of water between them and any accessible area. The facility itself, being underground, is surrounded on all sides by dirt. Individual sources in the facility are located on the floor of the pool and are arranged in such a fashion that one large source of approximately 1075 curies is in the center of this floor. Surrounding this source in a circle are 78 radioactive pencils each consisting of 9 slugs of cobalt 60. Each slug contains a little less than 5 curies of cobalt 60 which results in each pencil having an activity of approximately 43.5 curies. The pool facility is provided with an underwater storage rack where all or part of the pencils may be kept if it is desired to use fewer than 78 pencils for a certain experiment. Using all 78 pencils and the large center source, it is possible to provide underwater radiation fields of from 500,000 to 800,000 roentgens per hour. The pool is provided with several safety features.

1. A float is attached in such a fashion that if the water level drops by 6" or more, additional water will be pumped into replace that which is lost,

2. a device which senses water depth arranged in such a fashion that if the water drops 6" or more below normal level an audible alarm system is activated,

3. a radiation sensing device consisting of an ion chamber arranged in such a fashion that if the radiation level immediately above the pool exceeds 75 mr/hr an audible alarm system is activated. It was noted that a set of written radiation safety instructions have been provided for use with the irradiation facilities. In addition, the access door to the facility is kept locked at all times in the absence of Mr. Kneibler. Above the door to the facility an electric "Keep Out" sign is posted. Posted on the entrance door is a list of emergency instructions. Mr. Kneibler stated that the hazard sensing devices on the pool facility are checked monthly to be certain that they are operating properly.

It was learned that samples of water are removed from the pool every few days to make certain that the sources have not corroded or released

19-1398-4, 5, 6 - None of the facilities under license -4, 5, 6 were examined in that no material under these licenses has yet been procured. Mr. Bennert stated by phone that the laboratory facilities for handling the licensed material have not as yet been built due to a lack of funds, and that in all probability the facilities will not be constructed for a number of months.

19-1398-7 - A 23 millicurie and a 9 millicurie Co^{60} source used for instrument calibration and test by Mr. Evans are stored in the Critical Facilities test area. Neither source was in use at the time of inspection and both were stored in properly posted and labeled lead containers.

19-1398-8 - Facilities discussed under -2.

Mr. Stebbins stated that he has essentially no material on hand and that he does not anticipate doing any work in the near future under license -9. Material under this license would be used for checking the physical properties of irradiated material.

19-1398-9 - Materials under license -9 are stored in the waste room at the Martin Company. This facility consists of 2 adjacent rooms. In one room several barrels containing radioactive/waste material are stored in a corner. This corner is separated from the rest of the room by means of a large metal cabinet, an open steel frame, and a rope stretched between the cabinet and steel frame. In this corner a 7 millicurie cobalt 60 calibration source in a small big is stored behind 12" of concrete. In the metal cabinet several Sr^{90} sources totaling approximately 100 millicuries, which are used for calibration purposes, are stored. Also in the metal cabinet, a 1 millicurie thulium source not presently covered by any license issued to the Martin Company is stored. Other areas in this room are used for the storage of contaminated radioactive or other waste materials.

A reading of ½ mr/hr was obtained at the rope separating the corner from the rest of the room. At the surface of a bag of radioactive scrap material, a reading of 8 mr/hr was obtained. This bag of scrap along with several other bags of waste material was contained in the open frame shelves. Adjacent to this room, another room containing drums of radioactive material and 2 bottles of liquid radioactive wastes are stored. This room contains a device for the concentration of radioactive wastes.

Mr. Stefanec stated that the waste rooms are always locked in the absence of a responsible individual. It was further noted that outside of the waste storage facility, a number of barrels containing radioactive materials were stored on the ground. Mr. Stefanec said that these barrels contained either source material or special nuclear material waste.

Individuals working in this area are supplied with film badge service.

14. Instrumentation

Instrumentation on hand at the time of the inspection was supplied in a separate communication to Mr. Paul Elevin by Mr. Tony Stefanec. A list of this instrumentation is attached as Appendix A of this report.

15. Radiological Safety Precautions and Procedures

Instructions

In addition to radiation instructions as previously noted in the report, the Martin Company provides a printed volume of radiation safety instructions to all employees who work with radioactive material. This set of instructions includes a 5 page discussion of radiation and radiation protection written in simplified language and understandable to the layman. In addition to this preliminary explanation, the radiation manual contains a series of 20 health physics bulletins governing radiation safety in

...ent and rubber gloves are worn during most i... operations using radioactive
tool ... r ... ed
th ... these operations are performed. Mr. Banks
said t... radiation all workers operating radioactive tool tips, the
Fraser ... laboratory where the machining is done is thoroughly covered by the
Health Physics group.

Mr. Hutchins stated that he does not make routine surveys of the irradiation
facility, but that he does ... survey when he feels that the need arises.
An annual ... survey is made of the pool type irradiation facility
in the ... common ... to an alarm is arranged over the pool
in such a ... radiation level above the pool exceeds 75 mr/hr,
an audible ... system is activated.

Appropriate ... radiation surveys are conducted at the critical facility, and
records are maintained of these results.

Leak Testing

Leak testing of ... sources as required by license -2 and license -9 has
been carried ... out in an appropriate manner.

... under ... are removed from the pool facilities every few days and these
... leak ... checked for contamination. To date there has been no contamination.

Leak testing of polonium as required by license -1 has been carried out.

Locking of Areas

According to the individuals ... contacted, all areas where radioactive materials
are ... are locked and are kept locked whenever the responsible user of the
particular ... material in question is not present. Mr. Banks stated that door
... (Exhibit 1) to the ... radiographic facility is either locked or an individual
... this door during all ... radiographic exposures. Door #3 is normally
locked ... at all times ... except when equipment is being moved into or out of
... cubicle.

Procurement Procedures and Control

... applications for radioactive materials including special nuclear and
... source material ... must be processed through Mr. Hendel, who is in charge of licensing.
Radioactive materials ... are received by the responsible user in the original un-
opened shipping ... containers. A copy of ... the receiving procedure, for
both byproduct and ... source material, is included in the licensee's file.

17. Items

-1, 7 ... Listings of the sources obtained under these licenses is discussed
under Item ... 12, Facilities and Uses of ... Product Material (Items 4 and 7).

-2 - All ... material used ... with the exception of 25 millicuries of
Tm^{170}, which is stored in ... room, are stored in the radioisotope
laboratory ... except radiographic ... exposures. An 8 curie Ir^{192} source in a
Model A12 Tec... Operations Industrial Radiography camera, a 2.0 millicurie
Co^{60} source in ... Model ... tions Model 402 radiography camera, and a 25
curie Tm^{170} source ... in a lead pig are stored in the radiographic vehicle or
... radioisotope laboratory. Other materials ... under this license are kept in
a ... vault ... room fl... wall ... th a 2 ... steel cover.

-3 - All ... material ... under license -3, namely 9055 ... curies of Co^{60} are stored in
the gamma ... irradiation facility previously discussed. These are never removed
from their ... facilities.

-4, 5, 6 - ... materials are pro... only on hand under licenses

It was noted that the Martin Company has on hand a source of approximately 1 millicurie of Tm^{170}, stored in the waste room, which is not covered under any existing license.

18. Waste Disposal

There is no waste disposal of byproduct material under licenses -1, 2, 3, 4, 5, 6, 7, 8, 9.

19. Posting

-1, 7 - The access doors to the criticality area and test facility were properly posted and radiation sign and symbol. Containers housing the individual sources noted under facilities were properly labeled.

-2 - Mr. Banks stated that whenever radioactive material is being used in the hood, appropriate radiation signs and symbols are posted in the area.

It was noted that all industrial radiography cameras in the radiography cubicle were labeled with appropriate radiation caution sign and symbol. The radiography cubicle was not provided with an appropriate visible or audible alarm system as required by 20.203(c)(2). Mr. Banks stated that door "A" (Exhibit 1) to the radiography cubicle is either locked or a man posted at this door during all radiographic exposures. Door "B" is normally locked during radiographic exposures.

-3 - The gamma irradiation facility was posted with an electric sign above the entrance door instructing personnel to "keep out" of the area. It was further noted that the irradiation pig and the irradiation pool were posted with appropriate radiation caution sign and symbol. Written/Safety instructions required by Condition 15 of license -3 were posted in a conspicuous place.

Posting is not applicable under license -4, 5, 6, as no material is presently on hand under these licenses.

-8 - Material under license -8 is stored in the radioisotope laboratory and covered under posting as discussed in license -2.

-9 - Radioactive materials under license -9 are stored in the waste room. The Sr^{90} sources under license -9 and -2 and the unlicensed Tm^{170} source were labeled with appropriate radiation sign and symbol. Some of the waste containers in the area were properly labeled; however, numerous bags and other containers of radioactive waste material were not labeled appropriately. Labeling of all waste containers in this area would constitute satisfactory posting of the area.

20. Personnel Monitoring

Film badges are supplied weekly to all employees of the Martin Company who work with radioactive materials or in areas associated with this work. Personnel monitoring dosimeters are also available for use by all employees who have need for these devices. Film badge results were examined for the year 1957 and it was noted that no overexposures were received by personnel working with radioactive material.

On 3/9/57, a Mr. Clark received an exposure of 3700 mr. This exposure was due entirely to x-rays, as Mr. Clark was doing no work with radioactive material.

21. Records

Satisfactory records of isotope purchase, inventory, film badge results, and survey results where surveys have been conducted (see Item 15) are maintained. No results of leak tests of the Sr^{90} [illegible]

Marvin M. Mann, Assistant Director
Division of Inspection, Washington

Robert [illegible] Kirkman, Director
Inspection Division, [illegible]

DEC 31 1957

[illegible] - 10 CFR 30

[illegible] : [illegible] :PBK

Transmitted herewith is the following inspection report involving "non-compliance":

The [illegible] Company
Baltimore 3, Maryland

License No. 19-13[illegible]-1 through 9 except -4 which is superseded by -6

w/amend #1, 2 to -1
w/amend #1 to -2
w/amend #1 to -3
w/amend #1 to -6
w/amend #1 to -7
w/amend #1 to -[illegible]
w/amend #1 to -9

The following items of non-compliance were brought to the attention of Mr. Paul Guinn, who stated that these items will be corrected:

20.[illegible] "Caution signs, labels and signals" -(f)(1) "Containers": labeling of waste containers in waste storage area.

3[illegible].3 "License requirements": Licensee possesses a 1 millicurie Tm^{170} source not presently covered by a specific license.

Violation of Condition 14 of license 19-13[illegible]-2 and Condition 13 of license 19-13[illegible]-9 requiring leak testing of Tr^{90} sealed sources.

We feel that a slight hazard exists from the licensees failure to leak test Tr^{90} sources as required by licenses -2 and -9. We feel that essentially no hazard exists from the licensees failure to label [illegible] containers and acquire a license for the one millicurie Tm^{170} source.

It should be noted that this licensee 19-13[illegible]-2 has not been cited for failure to provide a visible or audible alarm system as required by [illegible]. In view of the physical set-up of the

A/

DEC 31 1957

adioisotope laboratory and associated facilities; and the fact that Mr. [illegible] stated that door "[illegible]" to the radiography cubicle is either locked [illegible] a man [illegible] at this door during all radiographic exposures, we do [illegible] feel that this type of device is necessary. Door "[illegible]" to the cubicle [illegible] locked during all radiographic exposures (See item 13, [illegible]).

[illegible] letter [illegible] to the [illegible] Company - Attention: [illegible] Paul Guinn, [illegible] Safety [illegible] - requiring correction of [illegible] items of non-compliance.

Director
Division of Licensing and Regulation
U. S. Atomic Energy Commission
Washington 25, D. C.

Attention Mr. Lyall Johnson
Chief, Licensing Branch

Dear Mr. Johnson:

Reference is made to our letter of December 12, 1957 transmitting three copies of an application for a general license to handle special nuclear material pursuant to Part 70, Title 10, Code of Federal Regulations.

In Appendix B of the referenced application, the following statement appears under item (2):

> "A description of the process is contained in the confidential manual, MND-1069 which is furnished as a supporting document to this application, (Appendix F)."

Enclosed are three copies of an unclassified Appendix F providing an unclassified description of the process for item (2). We now desire to withdraw the two copies of MND-1069 which were originally transmitted as Appendix F and we shall appreciate their immediate return.

See Reports File

There are also enclosed three copies of the revised Martin Criticality Precautions Manual, MND-1063, as Appendix A to the application. As noted in our letter of December 12, 1957 this revised manual was under preparation at the time of filing of the application.

UNITED STATES ATOMIC ENERGY COMMISSION

COMPLIANCE INSPECTION REPORT

1. Name and address of licensee or permit holder

The Martin Company
Baltimore 3, Maryland

2. Date of inspection

October 22, 1957

3. Type of inspection

Initial

4. 10 CFR part(s) applicable

20-40

5. License (or permit) number(s) and expiration date(s)

Number	Date	Exp. date	Number	Date	Exp. date
C-3572 w/amend #1,2	(Mr. E.R.McDonald Mr. C.A.Wendel)	6/1/58			
C-3147 and Rev. #1, w/amend #2	(Mr. T.F.Nagey)	6/1/58			
C-3508 and Rev. #1,2,3 w/amend #3,4	(Mr. C.A.Wendel)	6/1/58			

6. Scope of license(s) and permit

C-3572 - Authorized use of two hundred (200) pounds of Magnesium-thorium alloys, one gram of uranium metal and two grams of thorium metal for use, during the term of this license, in connection with work under government contracts.
C-3147 - Licensee authorized to receive possession of and title to one hundred and fifty (150) kilograms of refined source material during the term of this license for use in development studies and fabrication of experimental fuel elements. This license extends to the Nuclear Engineering Laboratories, and pilot manufacturing plant located at Middle River, Maryland.(CONT

7. Special conditions and limitations of license(s) or permit

C-3508 C-3147 C-3572
Licensee is required to maintain records of inventories, receipts and transfers of refined sour material. Neither this license nor any right under this license shall be assigned or otherwise transferred in violation of the provisions of the Atomic Energy Act of 1954.

8. Inspection findings

The Martin Nuclear Division engages in research and development and production activities at their facilities in Baltimore, Maryland. The facilities for use and handling of source material and radiation detection instrumentation are adequate. The Nuclear Materials Control Committee discussed, in Part 30 inspection report dated December 30, 1957, reviews, approves operating procedures, and s vested with managerial authority on health-safety and accountability to ensu that responsibilities of operating departments are carried out effectively. Procurement procedures, accountability, health and radiation safety, and source security were found to be adequate. Personnel monitoring, air and direct radiation surveys, and waste disposal records are satisfactory. All of the areas performing work under the above licensees were properly (CONT'D)

9. Items of noncompliance

20.203 "Caution signs, labels and signals" -(f)(2) failure of licensee to label with proper sign and symbol 6.6 lbs. container of uranium oxide. License C-3147.

10. Give date of last previous inspection: None

11. Is "Company Confidential" information contained in this report? No

ITEM 6 CONT'D

Licensed to receive possession of and title to, and to transfer to authorized licensees, seven (7) pounds of refined source material for use in research and development.

C-3503 - Licensee authorized to receive possession of and title to thirty-five hundred (3500) pounds of magnesium-thorium alloys during the term of this license for use in connection with the Navy Vanguard Program.

ITEM 8 CONT'D

posted in accordance with 10 CFR 20. However, under license C-3147, a fibre pak container containing 6.6# of UO_2 was labeled with radiation caution sign and symbol (Paragraph 18).

PART 40 INSPECTION

The Martin Company
Baltimore 3, Maryland

Date of Inspection: October 22, 1957

Persons Contacted:

C-3508 C-3147 C-3572

Mr. C. A. Wendel, Licensing Officer, Nuclear Division
Mr. L. D. Bradley, Assistant Contract Manager, Vanguard
Mr. Joe Kalb, Superintendent, Material Control
Mr. Robert Spangler, Superintendent, Production Activity
Mr. Maxwell, Chief, Engineering Laboratory
Mr. Bierds, Jr., Assistant Chief, Engineering Laboratory

12. Organization and Administration

C-3508 C-3147 C-3572

Same as described in Part 30 inspection report dated December 30, 1957.

13. Facilities and Uses of Source Material

C-3508

The Thorium Magnesium obtained under this license is for a secret project for the Department of Defense. The material in use is kept guarded in an exclusion area within Plant #2, in which authorized personnel perform assembly work and a small amount of scrap chipping. The material is marked with the words, "Magnesium and Thorium." The weight of this material (2' x 3' x 1/8") is less than that requiring posting and labeling according to the requirements in Part 20. The operations are performed in the Sheet Metal Department of Plant #1, and involve the following:

1. Forming of shapes.
2. Dimpling and drilling holes.

No film badges are worn by personnel working on this project.

C-3147

Under this license 65% of Uranium oxide plus aluminum powder is used to manufacture bushings .238 id x .248 od x 3/4 inch long. The powder metallurgy operations involved are:

1. Pouring powder into a die and pressing.
2. Sintering pressed powder.
3. Stringing bushings into a 24 inch length.
4. Grading the bushings.
5. Pouring into aluminum jackets and hot pressing.

The bushings are fabricated under contract for Phillips Petroleum Company. The operations are done inside a locked and posted metallurgy laboratory which contains hoods, hydraulic presses, two Stanet powder rolling mills, a large rolling mill, Fenn swaging unit, vacuum furnaces, induction furnaces, and other allied equipment. The floor of the room is covered with asphalt tile and the work benches are covered with stainless steel.

C-3572

Work under this license has been completed. Facilities used are the same described as for license C-3147.

14. Radiological Safety Precautions and Procedures

C-3508 C-3147 C-3572

Same as Part 30 write-up, December 30, 1957.

C-3147 C-3572

Film badges are worn by personnel working under these licenses. See Part 30 report dated December 30, 1957.

C-3508

Personnel do not wear film badges.

15. Instrumentation

C-3508 C-3147 C-3572

Instrumentation is listed as Appendix "A" to Part 30 report of December 30, 1957.

16. Procurement Procedures and Control

C-3508 C-3147 C-3572

See Paragraph 16 of Part 30 report dated December 30, 1957.

17. Waste Disposal

C-3147

According to Mr. Guinn, Health Physicist, a waste disposal area is presently under going construction. The waste disposal area includes a recovery and incineration area. To date, according to Mr. Guinn, there has been no incineration, inasmuch as no filter system was available to contain any ashes. Wastes awaiting incineration are presently being stored in posted, sealed 55 gallon drums until the wastes can be disposed of. A waste recovery building is undergoing construction. When the recovery system is completed all radioactive waste waters will be pumped into a sump and then pumped through a filter system into holding tanks for storage. If the stored waste samples are found to contain less than 220 dpm per liter, they are released to the sewer system. The average flow from the Martin Plant is 4 million gallons of water per day.

Mr. Guinn stated that his Health Physics Office monitors the flow of water into the sewer system and submits monthly reports to the Maryland State Department of Health Sanitation Engineering Department.

C-3508

No disposal has been made to date of the Thorium Magnesium scrap. The scrap materials, according to Mr. Spangler, are stored in a 55 gallon container.

Mr. Guinn stated that until the recovery facilities are completed, the wastes will be contained in 55 gallon drums immediately adjacent to the recovery area. These were inspected and noted to be properly labeled, with radiation warning sign and symbol. The area was posted with radiation sign and symbol.

18. Posting

C-3147

A fiberpak container shipped to the licensee by Mallinckrodt Chemical Works, St. Louis, Missouri, contained 6.6 lbs. of UO_2 sources and was not labeled with the proper radiation sign and symbol. The large cabinets in which the source material was contained were properly labeled.

C-3508

The magnesium thorium sheets were not marked with radiation sign. This material, received from Dow Chemical Company had written on each of the containers the words "Magnesium Thorium Alloy". Neither the individual sheets or the area required posting at the time of this inspection.

19. Records

C-3508 C-3147 C-3572

Records of inventory, procurement purchase, disposal, film badge results and results of surveys are maintained.

20. Surveys

C-3508 C-3147

Mr. Guinn stated that both direct radiation and air surveys have been taken at the facilities used by both licensees. A letter stating the results of these surveys is included in the licensee's file. The survey results were all negative.

DOCKET

70-58

File C

January 12, 1958

Manager
U. S. Atomic Energy Commission
Schenectady Operations Office
P. O. Box 1069
Schenectady, New York

Attention: Mr. V. V. Hendrix
Director
Reactor Eng. & Technical Services Division

Gentlemen:

On October 25, 1957, I sent you a letter requesting an opinion on raising the allowable storage capacity of our vault to six hundred kilograms of U235.

Attached is a sheet containing a sketch of our vault storage area and calculations regarding the maximum quantities of U235 which can be stored in the various storage devices to be used. For consistency with a figure submitted to the Licensing Branch, we are revising our maximum limit to 500 kilograms of contained U235.

I trust that the data presented will enable you to respond to our inquiry.

Very truly yours,

THE MARTIN COMPANY

Marvin [illegible], Assistant Director
Division of Inspection, Washington

Robert [illegible], Director
Inspection Division, [illegible]

[illegible] - [illegible] 40

[illegible]

Transmitted herewith is the following inspection report involving "technical non-compliance":

The Martin Company
Baltimore 3, Maryland

Licence Nos. C-3508
C-3147
C-3572

No items of non-compliance were found for C-3508 and C-3572.

For licence C-3147, the licensee was found in non-compliance with the following item, which he agreed to correct.

20.203(f)(2) "Caution signs, labels and signals": failure of licensee to label with proper sign and symbol 6.6 lbs. container of uranium oxide.

We feel that essentially no hazard exists with the licensee's failure to label containers.

We recommend that a letter be sent to the licensee requiring him to label containers.

Enclosure:
Insp. rpts. (2)

Washington 25, D. C.

Attention Mr. Lyall Johnson
Chief, Licensing Branch

Dear Mr. Johnson:

Pursuant to Mr. Delaney's request, there are enclosed additional copies of each of three documents relating to The Martin Company's application for a general license, reference Mr. Nagey's letter of January 13, 1958.

The enclosures are:

(1) Criticality Precautions Manual, MND-1063
(2) Mr. Nagey's letter of January 13, 1958, attaching
(3) Appendix F (unclassified)

It is now understood that instead of returning the two classified copies of MND-1069 to The Martin Company as we requested, you will destroy these and so advise us in a letter.

Very truly yours,

THE MARTIN COMPANY

Attention Mr. Lyall Johnson
Chief, Licensing Branch

Dear Mr. Johnson:

Three copies of the revised copy of the Criticality Precautions Manual, MND-1063 were transmitted to you on January 13, 1958 under cover of a letter signed by Mr. Nagey.

In the meantime it has come to our attention that three deletions in the manual should be made. These are as follows:

Page 9 - line 17 - delete last word

Page 12 - line 18 - delete next to last word

Page 12 - line 31 - delete eighth word

Kindly make these deletions not only in the four copies of the revised manual in your possession but in the copy of the original manual transmitted under cover of Mr. Nagey's letter of April 22, 1957.

Very truly yours,

THE MARTIN COMPANY

Office Memorandum • UNITED STATES GOVERNMENT

TO : H.L. Price, Director,
Division of Licensing and Regulation

DATE: FEB 7 1958

FROM : Marvin M. Mann, Assistant Director for Compliance
Division of Inspection

SUBJECT: THE MARTIN COMPANY, LICENSE NOS. 19-1398-1 through 9 except -4 which is superseded by -6
(10 CFR 30)

SYMBOL: INS:CCP

Attached is a copy of the inspection report, prepared by the New York Operations Office Inspection Division, concerning activities of the subject licensee.

Information gathered during inspection shows that the licensee was in non-compliance with the following:

License Condition No. 14 of License No. 19-1398-2 and Condidition No. 13 of License No. 19-1398-9. "Leak-testing of sealed sources".
Strontium 90 sealed sources are not tested as required.
(Paragraphs 8 and 15, page 6 of report)

10 CFR 20.203(f)(1) Caution signs, labels and signals.
Radioactive waste containers are not labeled as specified in this section. (Paragraphs 8 and 19-9, Part 30 Inspection of report, page 7).

10 CFR 30.3 License requirements.
Company possess 1 mc Thulium source without a license. (Paragraphs 8 and 13, page 5 of report).

Your attention is invited to the memorandum of transmittal prepared by the office that conducted the inspection. It is suggested that a letter be addressed to the licensee to inform him of the above non-compliance items and request that appropriate action be taken to correct or overcome these deficiencies. When corrective action has been completed on this matter, please furnish the office that conducted the inspection with copies of pertinent correspondence and these items will be checked during the next regularly scheduled inspection.

DOCKET NO. 40-2308

THE MARTIN COMPANY

Baltimore 3, Maryland

February 12, 1958

Director
Division of Licensing and Regulation
U. S. Atomic Energy Commission
Washington 25, D. C.

Attention Mr. Joseph Delaney

Gentlemen:

Reference is made to Source Material Licenses No. C-3508, Amendment No. 4 dated May 9, 1957 and C-3572, Amendment No. 2 dated May 7, 1957.

Request is hereby made for the consolidation of these two licenses into a single one under which The Martin Company will be authorized to receive possession of and title to 10,000 pounds of magnesium-thorium alloys for developmental and production purposes at its Middle River, Maryland facilities.

In addition to projects of the Martin Baltimore Division, it is contemplated that some fabrication work will be performed for the Denver Division of the Martin Company under transfers from Denver's Source Material License No. C-3670, Revision 3 dated February 19, 1957. Later similar services may be done for Martin Orlando Division if that unit obtains thorium alloys under AEC license.

The Martin Company has now centralized control of thorium-magnesium materials used at its Middle River facilities. These materials are now retained in inventory in a special enclosed area and are distributed under strict accountability procedures to various operating projects. Monitoring of activities under direction of the Martin Health Physics Supervisor, Mr. Paul Guinn, is performed to ensure that requirements of Part 20 CFR 10 are followed.

Very truly yours,

THE MARTIN COMPANY

Gentlemen:

Pursuant to the Atomic Energy Act of 1954 and Section 40.21 of the Code of Federal Regulations, Title 10 - Atomic Energy, Chapter 1, Part 40 - Control of Source Material, you are hereby licensed to receive possession of and title to ten thousand (10,000) pounds of thorium-magnesium alloys, one gram of uranium metal and two grams of thorium metal for use, during the term of this license, in connection with your work under government contracts.

You are further licensed to transfer and deliver possession of and title to refined source material to any person licensed by the Atomic Energy Commission, within the limits of his license.

As a condition of this license, you are required to maintain records of your inventories, receipts and transfers of refined source material.

This license is subject to all the provisions of the Atomic Energy Act of 1954 now or hereafter in effect and to all valid rules and regulations of the U. S. Atomic Energy Commission, including 10 CFR 20, "Standards For Protection Against Radiation."

Neither this license nor any right under this license shall be assigned or otherwise transferred in violation of the provisions of the Atomic Energy Act of 1954.

This license shall expire February 28, 1959.

STANDARD FORM NO. 64

Office Memorandum • UNITED STATES GOVERNMENT

TO : Files
(THRU) J. G. Delaney, Chief, Materials Section

DATE: February 27, 1958

FROM : C. P. McCallum

SUBJECT: THE MARTIN COMPANY APPLICATION FOR SPECIAL NUCLEAR MATERIAL LICENSE - DOCKET NO. 70-58

ANALYSIS AND FINDINGS

An analysis of the application for a special nuclear material license executed December 6, 1957, submitted by The Martin Company has resulted in the following observations, conclusions and findings. The application has been considered as a request for amendment to The Martin Company's License SNM-53.

The applicant requests that it be licensed to receive five hundred kilograms of U-235 contained in uranium of any enrichment of the U-235 isotope for use in the development and fabrication of reactor fuel elements.

The proposed use of the special nuclear material is for the conduct of research and development activities of the type specified in Section 31 of the Act.

Based upon our review of the information furnished by the applicant, it is hereby determined that the applicant is qualified by reason of training and experience to use the special nuclear material for the purpose requested and that the applicant's procedures, facilities and equipment are adequate to protect health and minimize danger to life or property. The applicant's procedures to avoid accidental criticality have been found to be adequate.

The application contains adequate financial and corporate data.

The application has been notarized.

No allocation of special nuclear material is required.

It is therefore determined that the application meets the requirements of the Act and the regulations of the Commission and that a license may be issued authorizing the activities proposed by the applicant.

APPROVED:

Lyall Johnson
Chief, Licensing Branch

THE MARTIN COMPANY

Baltimore 3, Maryland

February 28, 1958

Refer to:
AJS:W-711

Mr. W. O. Miller
Isotopes Branch
Division of Licensing and Regulations
1717 H Street
U. S. Atomic Energy Commission
Washington 25, D. C.

Dear Mr. Miller:

You have brought to our attention that during the last AEC isotopes inspection, there were three items of deficiencies. These were (1) a Strontium 90 source authorized under license no. 19-1398-2 was being used by Health Physics, (2) a 1000 mc Thulium source purchased in March of 1955 and authorized by license no. 19-1398-2 was being kept by Health Physics in their storage well to decay, and (3) bags of radioactive waste stored in our waste room unmarked.

We have corrected these deficiencies in the following manner:

Item I. The Strontium 90 source has been removed from license no. 19-1398-2 and placed on Health Physics license No. 19-1398-9. This change was made 20 December 1957.

Item II. The Thulium source was returned to the Radioisotopes Lab where all sources authorized by license no. 19-1398-2 are kept. Since this source is of no use to us, we are planning to return it to the vendor.

Item III. All containers of radioactive wastes are being properly marked before storage.

Very truly yours,

THE MARTIN COMPANY

ATOMIC ENERGY COMMISSION

SPECIAL NUCLEAR MATERIAL LICENSE

Pursuant to the Atomic Energy Act of 1954 and Title 10, Code of Federal Regulations, Chapter 1, Part 70, "Special Nuclear Material Regulations," a license is hereby issued authorizing the licensee to receive and possess the special nuclear material designated below; to use such special nuclear material for the purpose(s) and at the place(s) designated below; and to transfer such material to persons authorized to receive it in accordance with the regulations in said Part. This license shall be deemed to contain the conditions specified in Section 70.32(a) of said regulations, and is subject to all applicable rules, regulations, and orders of the Atomic Energy Commission now or hereafter in effect and to any conditions specified below.

Licensee

1. Name: The Martin Company

2. Address: Baltimore 3, Maryland

3. License No.: SNM-53, as amended

4. Expiration Date: February 28, 1961

5. Docket No.: 70-58

6. Special Nuclear Material

Uranium enriched in the U-235 isotope

7. Maximum quantity of special nuclear material which licensee may possess at any one time under this license

Five hundred (500) kilograms of U-235 contained in uranium enriched in the U-235 isotope as UO_2 and metal.

8. Authorized use: For the development and fabrication of reactor fuel elements in accordance with the procedures described in the licensee's application dated October 11, 1956, as amended October 24, 1956, and as amended by amendments executed December 6, 1957 and January 15, 1958.

9. Quantity of special nuclear material allocated to licensee pursuant to Section 70.31(b) of said part

None

CONDITIONS

10. Unless otherwise specified, the authorized place of use is the licensee's address stated in Item 2 above.

Place of use: licensee's Middle River Plant, Maryland.

APPENDIX A

	Procedure for Calculating Maximum Allowable Fissionable Material Masses	A-1

2.001.0 INTRODUCTION

2.001.1 Special nuclear materials in certain configurations and masses are capable of initiating a nuclear reaction. Such a reaction could result in a nuclear incident involving the release of radioactive fission products and other radioactivity with possible damage to personnel and surrounding property.

2.001.2 United States Atomic Energy Commission, (AEC), regulations, based on the Atomic Act of 1954, require industrial firms engaged in the handling of nuclear materials to establish procedures to protect the health and safety of the public. The procedures outlined here are designed to comply with all applicable AEC requirements in this connection.

2.002.0 APPROACH TO PROBLEM

2.002.1 A Nuclear Materials Controls Committee shall review and approve standards and procedures for the handling of all nuclear materials in the Martin Nuclear Division. The Committee is composed of representatives of the following:

General Manager's Office; (Chairman) Martin Nuclear
Engineering Department; Martin Nuclear
Finance Department; Martin Nuclear
Manufacturing Department; Industrial Relations, Martin Baltimore
Health Physics Services; Martin Nuclear
Quality Control Department; Quality Division, Martin Baltimore
Security Department; Industrial Relations, Martin Baltimore

2.002.2 Approved general standards and procedures are set forth with respect to criticality precautions in Sections 2.003 through 2.005 of this manual. Specific procedures for various facilities are included in Sections beginning with 2.006.

2.002.3 Copies of the Criticality Precautions Manual, after approval by the AEC, shall be distributed to corporate officers, all senior managerial personnel of the Martin Nuclear Division, and selected operating personnel. These manuals will be used for reference whenever necessary.

2.002.4 Additions to and revision of standards and procedures shall be the responsibility of the Nuclear Materials Controls Committee. These changes shall be forwarded to the AEC for review.

2.003.0 ENFORCEMENT

2.003.1 Enforcement of criticality procedures with respect to movement of special nuclear materials between work areas shall be the responsibility of the Accountability Representative. Responsibility for handling of these materials in accordance with approved procedures within work areas shall rest with the facility supervisors.

2.003.2 The Accountability Representative may delegate responsibility to his area supervisors. Upon delegation of responsibility, the Accountability Representative must assure himself that the area supervisors are fully informed regarding the procedures as set forth.

2.003.3 Infractions of criticality procedures shall be reported by the Accountability Representative, the Criticality Engineer, or the Facility Supervisors. The Nuclear Controls Management Committee shall make appropriate recommendations, after learning the circumstances, as to any action required to prevent recurrences of such incidents.

2.004.0 MEANS OF CONTROL

2.004.1 The basic criteria shall be in terms of grams of special nuclear material per square foot of Work Area or in terms of grams of special nuclear material per unit volume. Separate work areas are established with specific allowable limits for amounts of special nuclear material to be present at any one time.

2.004.2 Critical Work Areas - A work area is an area where there can be no nuclear interaction of material from one zone to another, (i.e., the perimeter of the zone may be shielded or the distance between material inventories within criticality zones is so great as to preclude the possibility of forming a critical mass).

Effective physical control is maintained with regard to the transfer of special source material into or out of the zone.

The Accountability Representative, or his designee who is aware of the criticality precautions, shall monitor material flow and storage between work areas.

A sign or suitable visible record shall be present indicating the allowable limit of nuclear material, present inventory of nuclear material, and the name of the supervisor charged with responsibility for the zone.

2.004.3 Allowable Limits for Special Nuclear Materials - The allowable limit for nuclear materials for each work area will be established on the basis of nuclear calculation as set forth in Ref. 1.

Each work area shall have its perimeter indicated by a two-inch band of paint unless otherwise designated. Off-spots for carriers of special nuclear material will be similarly designated in each critical work area.

The Criticality Engineer shall calculate the allowable limits for special nuclear materials for the various forms and configurations in which it will be used.

2.005.0 EMERGENCY PROCEDURES

2.005.1 Prominent signs at each facility shall outline rules for the employee action in the event of an emergency incident. In case of an accident the Emergency Director of the Facility, Accountability Representative, Security Officer, Criticality Engineer, and Health Physicist shall be notified immediately.

2.005.2 Person in charge - A qualified individual (with an alternate) shall be designated as Emergency Director for each facility to assume immediate responsibility in any emergency which may develop. The Emergency Director shall immediately consult with the Health Physics Representative, the Security Officer, the Criticality Engineer, and the Accountability Representative and assign responsibilities for implementing emergency procedures.

2.005.3 Control and monitoring of personnel - The area will be evacuated immediately and all personnel monitored for radioactive contamination. All personnel re-entering the area will be equipped to cope with the emergency situation. Dependent on the nature of the emergency, further medical checks as deemed necessary by the Health Physicist or Medical Director will be accomplished.

2.005.4 Movement of fuel - All special nuclear material in any work area affected by an emergency will, dependent on accessibility, be removed to a fireproof repository or returned to the storage vault. Should it be necessary to remove special nuclear material from more than one work area, insofar as possible the quantities will be kept segregated in carriers or birdcages to prevent criticality conditions. In any event, no more than a quantity equivalent to the combined allowable limits of any two work areas will be placed in proximity to each other without being in a carrier or birdcage. An emergency team assigned by the Plant Protection Department, the Emergency Director, or Plant Superintendent acting under the direction of the Criticality Engineer, will remove all materials.

2.005.5 Theft or losses - If theft or loss of radioactive material[1] is suspected, the Emergency Director of the facility involved shall immediately notify the Health Physics Supervisor (or in his absence, the Licensing Officer) and the Nuclear Division Security Officer. Upon their determination

that an actual theft, or an unaccountable loss of such quantity that a substantial hazard exists which might seriously affect persons in unrestricted areas, the General Manager of the Nuclear Division and the Corporate Director of Information Services of the Martin Company will be immediately advised of all pertinent details by the Health Physics Supervisor.

If it is suspected that the theft or loss involves radioactive material furnished under governmental contract, the Health Physics Supervisor (or in his absence, the Licensing Officer) will report the incident immediately by telephone and telegraph to the Manager, (or the Nuclear Materials Management Officer) of the Schenectady Operations Office, AEC; telephone Schenectady EXpress 3-6611. Both communications will contain pertinent facts including type of loss and manner of suspected theft.

If the incident should involve licensed radioactive nuclear material, the Licensing Officer (or in his absence, the Health Physics Supervisor) will report this immediately by telephone to the Manager of the New York Operations Office, AEC, New York City; telephone PLaza 7-3600 and also send a confirming telegram to the same office, address 70 Columbus Avenue, New York 23, New York.

2.005.6 Accidents - In case of an accident involving radioactive materials, the stipulated emergency procedures for the facility shall be followed. An immediate report by telephone shall be made and a confirming telegram shall be sent as outlined for theft or losses. The Manager of the Schenectady Operations Office shall be informed when licensed material is involved.

The Health Physics Supervisor, with the assistance of others concerned, will make a written report to the Director of the Division of Civilian Application, AEC, Washington 25, D. C. within thirty days of the occurence of an accident involving licensed radioactive materials pursuant to Part 20, Title 10 CFR as amended 10 May, 1957.

A similar report prepared by the Health Physics Supervisor will be made to the Schenectady Operations Office of any accident involving radioactive materials obtained under governmental contract.

2.005.7 Information to public - All information for public dissemination will be cleared through Martin Information Services monitored by AEC approval.

2.005.8 Critical Experiment Facility - The detailed emergency procedures covering the critical experiment facility are outlined in Operational Procedures Manual, Martin Critical Experiment Facility, MND-1111. Procedures for reporting are the same as those for the other nuclear facilities of The Martin Company.

1 - Includes source material, special nuclear material and by-product material (radioisotopes).

2.006.0 DESCRIPTION OF FACILITIES AND PROCESSES FOR PILOT MANUFACTURING PLANT

2.006.1 Description of Facilities - Physical layout of the manufacturing plant is shown on the floor plan. For reference, the adjoining nuclear engineering laboratory is now shown. The manufacturing area is partitioned from the remainder of the building by masonry walls extending from floor to ceiling. The floor is reinforced concrete. Sole entry is through a set of double doors which are either locked or under guard at all times.

The storage vault is a fully-enclosed room, 22 feet 8 inches long by 13 feet 9 inches wide and 11 feet high. Walls will be a minimum of nine inches thick and made of reinforced concrete. Ceiling and floor will be of the same construction.

Sole entrance to the vault will be through a $1\frac{1}{2}$-inch solid steel door equipped with an approved combination lock.

There will be no water conduits or other service piping and no drains within the vault.

2.006.2 Storage Containers - The birdcage for storing and transporting uranium dioxide powder and powder blends of uranium dioxide with non-fissionable materials will be a skeletal box-like device enclosing a cavity for holding the containers for the uranium dioxide powder and blends. The birdcages will be of welded metal construction and so dimensioned that there will be a minimum distance of six inches from the cavity walls to the outer boundaries of the birdcage. They will be provided with means to hold the container firmly in the cavity and for locking the lid of the birdcage. Dimensions of the Martin UO_2 powder birdcage are 16 5/8 inches by 16 5/8 inches by 21 3/8 inches high.

The containers for the special nuclear material powders will be smooth, spherical-bottomed, stainless steel cylinders provided with firm attachable stainless steel covers capable of affecting an airtight seal.

The birdcages for holding fuel element tubes and special nuclear material other than powders are 12 inches by 12 inches by 30 inches high. These will be of the same general type of construction as that for the retention of powders except that the internal container will be a wooden cradle designed to hold fuel element tubes, fuel element plates, bundles of

tubes, or boxes of fuel element plates. The type of cradle for the MPR tubular elements will be 9 1/2 inches by 11 3/4 inches by 23 3/4 inches and will provide for the storage of 50 separate tubes.

The dimensions for the type of birdcage used to hold annealing boats, sintering boats, and scrap containers are 12 inches by 12 inches by 39 3/4 inches. The dimensions of the cradle centered within the birdcage which holds the various boats and scrap container are 9 1/2 inches by 11 3/4 inches by 26 inches.

The transport vehicle will be a four-wheeled cart modified by the addition of a metal framework superstructure to hold securely the birdcage carriers while being moved.

2.006.3 Allowable Limits for Work Areas - The Criticality Engineer has determined the theoretical limits for the amounts of special nuclear materials in the various material forms relating to the fabrication of stainless steel clad enriched uranium dioxide tubular fuel elements. Reference, Appendix A.

These limits are based on the theoretical limits for the various forms using the optimum mixture of water and fuel-bearing aggregates. For this reason, the results are used as allowable limits and no additional factor is applied for "double batching" except in Form III. Limits for other forms have been determined using either similar calculations or provision for accidental "double batching" in the presence of a moderator. These limits are shown on pages 10 and 11.

2.006.4 Procedures for Specific Work Areas - All manufacturing operations will be performed in accordance with the detailed instructions set forth in the Manufacturing Manual. The allowable limits in 2.006.3 apply to the forms indicated for specific work areas. Additional limits for combinations of forms present at the same time are shown.

WORK AREA I (VAULT AND VAULT ANNEX ROOM)

Vault Room (1 A)

Floor Area ---------- 312 square feet

Forms: I, IIa, IIb, IV, V, VI, VII, VIII, IX, X, XI

FORM	ENRICHMENT OF URANIUM IN ISOTOPE U235	TYPE OF MATERIAL	ALLOWABLE LIMIT IN ANY WORK AREA (grams of contained U235)
I	highly enriched	UO_2 powder, density when loose approx. 5 gr/cc	800 grams
IIa	highly enriched	UO_2 and stainless steel mixture, density approx. 8.4 gr/cc	1600 grams
IIb	highly enriched	Sintered cermet of UO_2 and stainless steel density approx. 8.4 gr/cc	1850 grams
III	all enrichments	Uranium in aqueous solution	2 grams/liter [1]
IV	highly enriched	Stainless steel clad tubes, with Form IIb as fuel marrow	2000 grams
V	highly enriched	Stainless steel clad plates with uranium metal as fuel marrow	1600 grams
VIa	over 20.0%	Uranium metal in thin forms; ribbon, foil wire, etc.	500 grams
VIb	over 20.0%	Uranium metal in fine cuttings, dust., etc.	500 grams
VIIa	all enrichments	UO_2 and powdered Al mixture, approx. density 2.5 gr/cc	800 grams
VIIb	all enrichments	Pressed or sintered UO_2 and Al mixture in (VIIa) approx. density 5.0 gr/cc	800 grams

1 Except when amount in any one container in all forms does not exceed 400-grams of U-235

FORM	ENRICHMENT OF URANIUM IN ISOTOPE U235	TYPE OF MATERIAL	ALLOWABLE LIMIT IN ANY WORK AREA (grams of contained U235)
VIIIa	all enrichments	Aluminum alloy clad tubes with Form VIIb as fuel marrow	800 grams
VIIIb	over 20.0%	Iron-aluminum alloy clad tubes with Form VIIb as fuel marrow	800 grams
IX	over 20.0%	Uranium metal in buttons, derbies, etc.	10,000 grams [2]
X	over 20.0%	Uranium metal in ingots, bars, machined shapes, smallest dimension > 0.25 inches	2000 grams
XI	0.72% to 20.0%	Stainless steel clads filled with solid pellets of Form Ib or Ic	2000 grams

2 Subject to review regarding minimum dimensions and reflectors

Allowable Capacities of:

Total in storage devices	500 kilograms U-235
Form I, per storage device	600 grams U-235
Form IIa, per storage device	800 grams U-235
Form IIb, per storage device	900 grams U-235
Form IV, per storage device	1000 grams U-235
Form V, per storage device	800 grams U-235
Form VIa, per storage device	1000 grams U-235
Form VIb, per storage device	500 grams U-235
Form VII, per storage device	800 grams U-235
Form VIII, per storage device	800 grams U-235
Form IX, per storage device	10,000 grams U-235
Form X, per storage device	3000 grams U-235
Form XI, per storage device	2000 grams U-235

Receipt and Storage of Special Nuclear Material (SNM): It is planned that the special nuclear material will be transferred from the processor in lots each comprising one birdcage shipping device containing five polyethylene bottles, each holding two pounds of dry enriched uranium oxide. The birdcage is roughly cubical with dimensions of 3 feet 9 inches by 3 feet 7 inches by 3 feet 8 inches and provides 12 inches of air space around each container.

Upon receipt of a shipment from Railway Express, it will be taken to the vault annex room, to be received by the Accountability Representative and a member of the Health Physics Group. Containers will be removed one at a time from the birdcage in the annex room and placed in the glove box in the annex room. The UO_2 powder will be transferred to a Martin container which will convey the following information: Container number, tare weight, net weight, and lot number. The material will be repacked and stored in wide-mouthed metal bottles of approximately 150 cubic centimeters capacity. No more than 600 grams of uranium oxide, enriched, will be stored in each metal bottle. One and only one bottle will be suspended inside each cubical birdcage-type structure, and no portion of the bottle can be closer than six inches to the outside of the structure. These birdcages may then be stacked in any manner and the uranium oxide in any metal bottle will be separated from any other SNM by at least 12 inches. The birdcages will be placed along the

22-foot 8-inch walls of the vault in a single line. One layer will store approximately 18 kilograms of UO_2. As more storage space is required a second or third layer will be added.

Vault Annex Room (1 B)

Floor Area ---------- 120 square feet

Forms: I, II, VI, VII, IX, X, per vault limits

IV, V, VIII, XI, XII, XIII, in transit per vault limits

Combined allowable capacity of U-235 in Forms I, IIa, IIb and VII------ 800 grams (This limit may be increased to 4000 grams when necessary to handle special lots, provided precautions are taken regarding containment and presence of moderators and reflectors). Special procedures will be followed as directed in writing by the Chairman of the Committee.

Issuing Special Nuclear Material: On receipt of an approved requisition form, the courier shall fill the order only after making the checks outlined in the Accountability Manual.

Only after establishing the propriety of the requisition, a designee of the Accountability Representative shall remove from the vault a Martin storage birdcage holding a Martin container of UO_2 powder to the annex room. In the annex room, a designee of the Accountability Representative shall transfer the container of UO_2 powder from the storage birdcage to a carrier designed specifically for the work area to which the UO_2 powder is being consigned. When the UO_2 powder must be transferred from the storage container in its entirety, or in part to another work area container, the two containers shall be placed in the glove box and the transfer of UO_2 powder made therein. The storage container will be placed back in the storage birdcage and returned to the vault. The work area container will be placed in the carrier made specifically for the work station to which this particular order is being consigned and signed out by the courier for delivery to the consigned work area.

WORK AREA 2 (POWDER ROOM)

Floor Area ---------- 480 square feet

Forms: I, IIa, VII

Combined Allowable Capacities in:

Forms Ia and IIa with Form I not to exceed 500 grams of this amount ---------- 1075 grams U-235

Forms I and VIIa, Form I < 550 grams ----- 800 grams U-235

Work Description:

Weighing of UO_2, BN, and metal powders

Sieving of UO_2, and metal powders

Calcining of UO_2 powder

Blending of UO_2, BN, and metal powder mix

Powder rolling of UO_2, BN, and metal powder mix

WORK AREA 3 (PARTIAL SINTER AREA)

Floor Area ----------156 square feet

Forms: IIa, IIb, IV

Combined Allowable Capacity of Material: 1600 grams U-235

Work Description: Partial sintering of UO_2, BN, metal powder compact

WORK AREA 4 (SHEAR, BRAKE, SWAGING, AND ASSEMBLY AREA)

Floor Area ---------- 650 square feet

Forms: IIa, IIb, IV, VIIb, VIII, XI

Combined Allowable Capacity in:

Forms IIa, IIb, and IV ---------- 1600 grams U-235
Forms VIIb and VIII---------- 800 grams U-235

Work Description: Shearing of core to rough blank size
Shearing of core to finish blank size
Forming of core blank into tubes
Swaging of core tube
Assembly of core, inner and outer cladding on to mandrel
cutoff of fuel elements to length

WORK AREA 5 (PRESS AND SINTER AREA)

Floor Area ---------- 400 square feet

Forms: IIa, IIb, IV, VIIa, VIIb

Combined Allowable Capacity in:

Forms IIa, IIb and IV ---------- 1600 grams U-235

Forms VIIa and VIIb ---------- 800 grams U-235

Work Description: Pressing dead ends onto core blanks
Full sintering of core blanks

WORK AREA 6 (ROLLING AND DRAWING AREA

Floor Area ---------- 1000 square feet

Forms: IIa, IIb, IV, VIIb, VIII

Combined Allowable Capacity in:

Forms IIa, IIb and IV ---------- 1600 grams U-235

Forms VIIb and VIII ---------- 800 grams U-235

Work Description:

Cold rolling of core blanks
Annealing of core blanks
Drawing of tubular fuel element assemblies
Annealing and bonding of tubular fuel element assemblies
Removal of mandrels from tubular fuel element assemblies

WORK AREA 7 (RADIOGRAPHY ROOM)

Floor Area ---------- 418 square feet

Forms: IIb, IV, V, VIII, XI

Combined Allowable Capacity in:

Forms IIb, IV, V, and XI ---------- 1600 grams U-235

Forms IIb, IV and VIII ---------- 800 grams U-235

Work Description:

Radiographic inspection of core blanks
Layout of core blanks
Radiographic inspection of fuel elements
Layout of fuel elements
Identity marking of core blanks and fuel elements

WORK AREA 8 (MACHINE SHOP AREA)

Floor Area ---------- 1430 square feet

Forms: IIb, IV, V, VI

Combined Allowable Capacities in:

Forms IIb and IV alone ---------- 1850 grams U-235

Forms IIb, IV and V (in absence of Form VI) ---------- 1600 grams U-235

Forms V and VI alone with maximum in Form VI of 350 grams ---------- 1000 grams U-235

Forms X and VI with maximum in Form VI of 350 grams ---------- 3000 grams U-235

Work Description:

Edge milling of core blanks
Cutting cladding free of draw mandrel
Finish-machining fuel elements to length
Resistance welding of dead ends to cermet strip
Seam welding of plates

WORK AREA 9 (CHEMICAL CLEANING AND PLATING ROOM)

Floor Area ---------- 637 square feet

Forms: IIb, III, IV, VI, X

Combined Allowable Capacities in:

Solid materials in Forms IIb and IV alone ------ 600 grams U-235

Solid materials in Forms IIb, IV and VI with maximum in Form VI of 400 grams ---------- 500 grams U-235

Form III, per liter ---------- 2 grams U-235

Work Description:

Chemical cleaning and surface preparation of tubular cores and cladding
Chemical polishing of fuel elements

WORK AREA 10 (WELDING AREA)

Floor Area ---------- 518 square feet

Forms: IIb, IV, V, VI

Combined Allowable Capacities in:

Forms IIb and IV alone ---------- 1850 grams U-235

Forms IIb, IV and V (in absence of Form VI) ---- 1600 grams U-235

Forms V and VI with maximum in Form VI of 350 grams ---------- 1000 grams U-235

Forms VI and X with maximum in Form VI of 350 grams ---------- 3000 grams U-235

Work Description:

Seal welding of fuel element ends
Seam welding of plates

WORK AREA 11 (INSPECTION AREA)

Floor Area ---------- 428 square feet

Forms: IIb, IV, V, VIII, VI

Combined Allowable Capacity in:

Forms IIb, IV and V ---------- 1600 grams U-235

Forms IIb, IV, V, VIII ---------- 800 grams U-235
Forms IIb, IV, V and VI, Form VI, 350 grams - 1000 grams U235

Work Description:

In-process inspection
Layout
Final inspection

WORK AREA 12 (RESEARCH AND DEVELOPMENT AREA)

Floor Area ---------- 673 square feet

Forms: IIa, IIb, IV, V, VII, VIII, XI

Combined Allowable Capacity in:

Forms IIa, IIb, IV, V ---------- 1600 grams U-235

Forms IIa, IIb, IV, V, VIIa, VIIb, VIII, XI -- 800 grams U-235

Work Description:

Research and development

WORK AREA 13 (TRANSPORT LANES)

Floor Area ---------- 1070 square feet

Forms: all forms

The capacity of a birdcage or carrier of material as specified under Work Area 1

Work Description:

On receipt of a carrier containing special nuclear material (UO_2) the courier shall transport the carrier to its consigned work area via the established transportation lane ONLY, NEVER ACROSS WORK AREAS. At the consigned work area, the courier shall first check the amount of special nuclear material in the consigned work area and then shall place the carrier in the OFF SPOT location within the consigned work area. At the OFF SPOT will be a bulletin board and a signal.

The courier shall post the signal as soon as he deposits the carrier in the OFF SPOT. The bulletin board shall carry information pertaining to the work area such as:

Allowable weight of U-235 or of material ------ XXXX grams
Allowable number of units ---------- XXXX pieces
Weight of U-235 or material currently in work area ---------- XXXX grams
Number of units in work area ---------- XXXX pieces
Weight of U-235 in solution ---------- XXXX grams
Concentration of U-235 in solution ---------- XXXX grams per liter

The courier shall first check to see that the amount of special nuclear material he is delivering does not exceed the allowable amount for the consigned work area in either weight of U-235 or of material or number of pieces. The courier shall then mark on the bulletin board the weight of U-235 or number of pieces that he has delivered to the consigned work area. The Plant Superintendent or his designated representative shall sign a receipt acknowledging delivery of the material to the work area. This receipt shall be returned immediately to the courier for recording the information in the log book.

NOTE: Only the courier is authorized to change the information on the bulletin board as to the amount of U-235 within a work area. Except in emergency, only the courier is authorized to deliver or remove special nuclear material to or from a work area. In any event this must be in accordance with established transportation controls.

Work Description:

Transporting of SNM between vault and work area and between work areas

WORK AREA 14 (SCRAP STORAGE AREA)

Floor Area ---------- 194 square feet

Forms: all forms

Allowable capacities of materials in individual repositories
same as Work Area 1

Work Description:

Storage of U-235 containing solid and liquid scrap

WORK AREA 15 (TRANSPORT TO CRITICAL FACILITY)

Forms: IV, V, VI, VIII, XI

Allowable capacity of U-235 in any form per birdcage transporting device ---------- 800 grams

Work Description:

Movement of finished fuel elements from Main Plant to Critical Experiment Facility by guard-escorted motor vehicle.

WORK AREA 16 (WASTE DISPOSAL AREA)

Forms: Disposable solid waste, III

Allowable Capacities in:

Form III and solid wastes in any one container ------- 400 grams U-235

Per liter ---------- 2 grams U-235 *

In solid wastes ---------- 200 grams U-235

Work Description:

Concentration of accountable liquid wastes
Incineration of contaminated accountable and non-accountable wastes

* Provided uranium is uniformly dispersed and no sludge formation or settling out can possibly occur

WORK AREA 17 (WASTE STORAGE AREA)

Forms: III, Solid wastes

Allowable Capacities in:

Same as Work Area 16

Work Description:

Storage of carboys or drums containing concentrated liquid wastes

WORK AREA 18 (WEIGHING STATION)

Forms: all forms except III

Capacities: As specified in 2.006.3 of this chapter, when handled alone and with the exception of material in birdcage devices

Work Description:

Weighing and measuring of materials for accountability purposes

WORK AREA 19 (ENGINEERING MATERIALS LABORATORY)

Forms: all forms

Allowable capacities in all forms combined with maximum in Form VI of 350 grams ---------- 800 grams U-235

Work Description:

Chemical analysis of samples and engineering tests
Development of fuel elements and experimental fabrication

WORK AREA 20 (POROSITY TEST AREA)

Floor Area ---------- 250 square feet

Forms: III, IV, V

Combined Allowable Capacities in:

Form IV and V ----------1600 grams U-235

Form III ---------- 100 grams U-235

WORK AREA 21 (FURNACE AREA)

Floor Area ---------- 500 square feet

Forms: IIa, IIb, IV, VIII

Combined Allowable Capacity in:

Forms IIa, IIb, and IV ----------1600 grams U-235

Work Description:

Diffusion bounding, sintering, pre-cleaning, annealing

WORK AREA 22 (AUTOCLAVE AREA)

Floor Area ---------- 160 square feet

Forms: IV, V, (totally immersed in H_2O)

Combined Allowable Capacity in Forms IV and V --------1600 grams U-235

Work Description:

Autoclaving of sealed fuel elements at 300 degrees Fahrenheit

WORK AREA 23 (VACUUM FURNACE AREA)

Floor Area ---------- 300 square feet

Forms: IX, X

Capacities: Allowable capacity in Form IX and X --------- 10,000 grams U-235

Work Description:

Melting, pouring and casting of uranium metal in vacuum

WORK AREA 23a (COOLING AREA)

Floor Area ---------- 150 square feet

Forms: X

Allowable capacity in Form X ---------- 10,000 grams U-235

Work Description:

Cooling and preliminary deslagging of cast ingots

WORK AREA 24 (SAWING AREA)

Floor Area ---------- 100 square feet

Forms: VI, IX, X

Combined Allowable Capacities in:

Forms VI, IX, and X with maximum in Form VI
of 350 grams ---------- 10,000 grams U-235

2.007.0 DESCRIPTION OF PROCEDURES FOR CRITICAL EXPERIMENT FACILITY

MND Report 1110, Part III, describes the Critical Experiment Facility. A detailed plan of the facility is shown in this report.

For purposes of accountability, the entire Critical Experiment Facility is a Materials Balance Area as described in MND-1111, Chapter IX, and in the Nuclear Materials Control Manual, MND-1069.

For purposes of criticality control, there will be two critical work areas in the facility:

WORK AREA 101 - The storage vault

WORK AREA 102 - The work area adjacent to the vault

The test cells, Work Areas 103 and 104 respectively, are not considered criticality control areas. Experimental test work involving critical quantities of special nuclear materials will be conducted under specific Class 104 Facilities Licenses issued pursuant to Part 50, Title 10, CFR using procedures described in Reports MND-1110, 1111, 1112 and others to follow.

Except for transit of special nuclear material to Work Areas 101, 102, 103, and 104, no special nuclear material will be handled in any other room or area of the facility.

WORK AREA 101 (VAULT ROOM)

Floor Area ---------- 176 square feet

Forms: IV, V, VI

Allowable Capacities of:

U-235 total in storage devices ---------- 100 kilograms

U-235 in any form per storage device ------- 800 grams

RECEIPT AND STORAGE OF SPECIAL NUCLEAR MATERIAL

As described, fuel tubes or plates will be moved to the Critical Experiment Facility in birdcage transportation and storage devices. These birdcage devices are 12 inches by 12 inches by 30 inches and retain in a center position wooden cradles 9 1/2 inches by 11 3/4 inches by 23 3/4 inches which hold the fuel tubes or plates. After

verification by the Accountability Designee of the Facility of the number of tubes or plates delivered (as described in MND-1069) the birdcages will be placed in the storage vault and arranged in rows along the back wall.

WORK AREA 102 (WORK ROOM ADJACENT TO VAULT)

Floor Area ---------- 460 square feet

Forms: IV, V, VI

Allowable capacity of U-235:

Forms IV and VI with maximum of 400 grams of U-235 in Form VI ---------- 2000 grams

Forms IV, V and VI with a maximum of 400 grams in Form VI ---------- 1600 grams

Work Description:

Assembly of Form IV tubes into bundles of 37 tubes each

Assembly of Form V plates into boxes of 18 plates each

Following assembly, the fuel elements (bundles or boxes) will be placed in wooden cradles which are held in the birdcage storage devices. The dimensions of the cradle holding a bundle of 37 MPR tubes are 9 1/2 inches by 11 3/4 inches by 23 3/4 inches.

The birdcage devices are then transferred to the storage vault for retention until withdrawal for authorized experimental work.

APPENDIX A

PROCEDURE FOR CALCULATING MAXIMUM ALLOWABLE FISSIONABLE MATERIAL MASSES

Basic Formulas

1. $k_\infty = 1 + M^2B^2$
2. $B^2 = (\frac{\pi}{\bar{R}})^2$
3. $\bar{R} = R + 7$
4. ρ = fuel density grams per cubic centimeter
5. y = volume per cent of fuel
6. Mass = $4/3\ \pi R^3\ y\ \rho$

Basic Systems

1. UO_2
2. UO_2 in stainless steel with boron (25 per cent UO_2, 1/4 per cent BN, remainder stainless steel Type 18-8)
3. U in water

List of Constants

			Atomic Weight
$\sigma_a\ (U_{235})$	= 670b		235
σ_a (O)	= 0.0002b	σ_s = 4.2b	16
σ_a (B)	= 750b	σ_s = 4b	10.82
σ_a (H)	= 0.33b	σ_s = 20b	1
σ_a (Fe)	= 2.4b	σ_s = 11b	55.85
σ_a (Cr)	= 2.9b	σ_s = 3b	52.01
σ_a (Ni)	= 4.5b	σ_s = 17.5b	58.69

Step 1 $\quad k_\infty = \eta f \qquad \eta = 2.08$ for U_{235}

System 1

$$f = \frac{\Sigma\ U_{235}}{\Sigma\ U_{235} + \Sigma\ H_2O}$$

$$= \rho\ y\ x\ \frac{0.93\ x\ \frac{235}{267}\ x\ 670}{235}$$

$$= \frac{}{\rho y \times \frac{0.93 \times \frac{235}{267} \times 670}{235} + (1-y) \times \frac{2 \times 0.33}{18}}$$

$$= \frac{1}{1 + (\frac{1-y}{\rho y}) \times 0.0156}$$

System 2

$$f = \frac{\Sigma U_{235}}{\Sigma U_{235} + \Sigma B + \Sigma H_2O \Sigma ss}$$

$$f = \frac{\rho y \times \frac{0.25 \times 0.93 \times \frac{235}{267} \times 670}{235}}{\rho y \left[\frac{0.25 \times 0.93 \times \frac{235}{267} \times 670}{235} + \frac{0.0025 \times 750}{24.8} + \frac{0.75 \times 0.74 \times 2.4}{55.8} + \frac{0.18 \times 0.75 \times 2.9}{52} + \frac{0.08 \times 0.75 \times 4.5}{58.7} \right] + (1-y) \frac{2 \times 0.33}{18}}$$

$$f = \frac{0.584 \rho y}{\rho y \left[0.584 + 0.0755 + 0.0238 + 0.0075 + 0.0046\right] + (1-y) \ 0.0367}$$

$$f = \frac{0.584 \rho y}{0.6954 \rho y + (1-y) \ 0.0367}$$

$$f = \frac{1}{1.19 + (\frac{1-y}{\rho y}) \ 0.0628}$$

System 3

$$f = \frac{\rho y \ \frac{670}{235}}{\rho \frac{670}{235} + (1) \frac{2 \times 0.33}{18}}$$

$$f = \frac{1}{1 + (\frac{1}{\rho}) \frac{0.66}{18} \times \frac{235}{670}}$$

$$f = \frac{1}{1 + \left(\frac{1}{\rho}\right) 0.0129}$$

Values of k_∞

System 1

$$k_\infty = \frac{2.08}{1 + \left(\frac{1-y}{\rho y}\right) 0.0156}$$

System 2

$$k_\infty = \frac{2.08}{1.19 + \left(\frac{1-y}{\rho y}\right) 0.0628}$$

$$k_\infty = \frac{1.75}{1 + \left(\frac{1-y}{\rho y}\right) 0.0528}$$

System 3

$$k_\infty = \frac{2.08}{1 + \left(\frac{1}{\rho}\right) 0.0129}$$

Step 2 $k_\infty = 1 + M^2 B^2$

assume $M^2 = T + L^2 = 35$ square centimeters

$$\frac{k_\infty - 1}{35} = \frac{\pi^2}{(R + 7)^2}$$

Step 3

1. Assume value of ρ and y;
2. Find k_∞ from proper formula (Equation 2);
3. Find R from formula (Equation 3);
4. Find mass allowable from formula (Equation 1);
5. Plot curves of mass (Step 4) versus y (Step 1) holding ρ constant (Step 1);
6. Plot curves of minimum mass from Step 5 versus ρ (Step 1).

2308

APR 1 1 1958

The Martin Co.
Baltimore 3, Maryland

Attention: Mr. Paul Guinn

Gentlemen:

This refers to the inspection conducted on October 22, 1957 of your activities authorized under Source Material License Nos. C-3572 with Amend. #1 and 2; C-3147 with Amend. #1; and C-3508 with Amend. #1,2,3,and 4; and Byproduct Material License Nos. 19-1398-1,2,3,5,6,7,8,and 9.

It appears that certain of your activities were not conducted in full compliance with the conditions of your Byproduct Material and Source Material Licenses and the requirements of the AEC's regulations in Parts 20 and 30, Title 10, Code of Federal Regulations in that:

1. The carton containing the 6.6 pounds of UO_2 was not labeled with the proper radiation signs as required by Section 20.203(f).

2. The 1 mc Thulium 170 source was not covered by a specific license as required in Section 30.3 of 10 CFR 30.

3. Leak tests of the Strontium 90 sealed sources were not carried out as required by Condition 14 of License No. 19-1398-2.

It is noted that these deficiencies were called to your attention and you agreed to take the necessary corrective action and verified in your letter of February 28, 1958 the action which would be taken. Particular attention will be given these items during the next inspection of your activities.

There were no other items of noncompliance reported to us as a result of this visit. We appreciate the cooperation given to the AEC representative.

Very truly yours,

James H. Mason, Chief
Isotopes Branch
Division of Licensing and Regulation

September 12, 1958

U. S. Atomic Energy Commission
Division of Licensing and Regulation
Washington 25, D. C.

Attention: Mr. J. C. Delaney
Chief, Materials Section
Licensing Branch

Gentlemen:

As you may know, the Denver Division of The Martin Company is engaged in the development and fabrication of the Titan missile, pursuant to a prime contract with the Air Force. The Baltimore Division of the Company will support this effort by producing certain of the missile components, an undertaking which will require the procurement of substantial quantities of thorium-magnesium alloy.

Specifically, it is anticipated that approximately 50,000 pounds of HK-31A alloy will be required during the next twelve months. I shall, therefore, appreciate it if you will issue a source material license for this quantity of thorium-magnesium alloy in accordance with the provisions of Section 40.21 of Title 10 of the Code of Federal Regulations. I shall, of course, be glad to furnish any additional information which may be required relative to this Application.

In connection with the same program, it will be necessary for us to procure additional quantities of the alloy during the remainder of 1959 and during 1960 and 1961. Applications for these additional quantities will be submitted on a timely basis.

Very truly yours,

THE MARTIN COMPANY

Gentlemen:

Pursuant to the Atomic Energy Act of 1954 and Section 40.21 of the Code of Federal Regulations, Title 10 - Atomic Energy, Chapter 1, Part 40 - Control of Source Material, you are hereby licensed to receive possession of and title to, at the above stated location, fifty thousand (50,000) pounds of thorium magnesium alloy containing not more than 4% thorium for fabrication.

You are further licensed to transfer and deliver possession of and title to refined source material to any person licensed by the Atomic Energy Commission, within the limits of his license.

As a condition of this license, you are required to maintain records of your inventories, receipts and transfers of refined source material.

This license is subject to all the provisions of the Atomic Energy Act of 1954 now or hereafter in effect and to all valid rules and regulations of the U. S. Atomic Energy Commission, including 10 CFR 20, "Standards For Protection Against Radiation."

Neither this license nor any right under this license shall be assigned or otherwise transferred in violation of the provisions of the Atomic Energy Act of 1954.

This license shall expire September 30, 1959.

DEC 1 [illegible]
Maa

Gentlemen:

You will recall that some time ago we discussed by telephone some of the problems relating to the handling of thorium-magnesium (containing 4% or less thorium) that have been encountered in the Baltimore Division of this Company. I explained at that time that this Division has made extensive use of this alloy in the past in connection with the fabrication of such Martin products as the Vanguard and Matador and that we anticipate using substantially increased amounts in connection with the Titan Missile. I also pointed out that because of this increased usage, and because of the minimal hazards presented, we believe it necessary to adopt a set of procedures which would be applicable to this particular alloy as distinguished from other types of source material.

Our Management Engineering Department has now prepared, and I am enclosing herewith, three copies of a document entitled "Proposed Procedure for Handling of Magnesium-Thorium." The document has been reviewed and approved by our Health Physics Department. Although this procedure is self-explanatory, I would like to call your attention to certain of the accountability aspects. While the procedure calls for very strict accountability with regard to scrap materials, we have not made provision for detailed accounting with respect to thorium-magnesium material which is fabricated into components. The weighing of such material would be wholly impracticable, in our particular circumstances, for the reason that the fabricated components are incorporated into complex assemblies containing various non-source materials before being shipped to Denver for final installation in the missile. It should be recognized, however, that all of the 4% thorium-magnesium procured by this Company is utilized in the performance of contracts with the Government. Consequently, the difference between the quantities purchased and the scrap realized represents, at any time, the amount that has been or will be delivered to the Government in the form of fabricated end items.

A/32

THE MARTIN COMPANY
Baltimore 3, Maryland

I shall appreciate it if you will review the enclosure and confirm to me that the proposed procedure set forth therein satisfies existing AEC requirements relative to the handling and accountability of 4% thorium-magnesium. While this procedure would be applicable only to the Baltimore Division, we would expect, subject to AEC concurrence, to institute substantially similar procedures in our other Divisions. We shall be glad to meet with you in your office if you desire any further information or if you have any questions regarding the proposed procedures.

Very truly yours,

THE MARTIN COMPANY

Ross G. Macaulay
Licensing Officer
Nuclear Division

PROPOSED 11-17-58
NO. 44.43
REVISION
ISSUED
PAGE 1 OF

☐ OPERATING INSTRUCTION
☒ STANDARD PROCEDURE

SUBJECT: Proposed Procedure For Handling Of Magnesium-Thorium

FUNCTIONS AFFECTED:
Material & Procurement
Manufacturing
Quality
Health Physics - Safety
Property Accountability

40-3296

REMARKS:

This procedure establishes the method of handling and processing alloys of Magnesium-Thorium containing 4% or less Thorium. Since this material is a licensed Source Material controlled by The United States Atomic Energy Commission, it is important that all raw material, work in process, offal, scrap, rejected parts, and surplus material be handled separately from other materials in accordance with the provisions of this procedure.

The Memorandum Procedure issued by this department on January 6, 1958 subject "Thorium Alloy - Accountability" is superseded by this Standard Procedure.

Additional copies of this Standard Procedure may be obtained by calling 9295 or 9327.

R. E. Weber
Management Engineering

DEC 1

AP-3 (9-58)

I Materiel & Procurement

A Purchasing

Specify in the purchase of all Magnesium-Thorium materials that material must be so designated and that all shipping papers must be marked with the net weight of the material.

B Stores

All Magnesium-Thorium material in Stores must be properly designated and may not be mixed with other types of materials.

NOTE: This means separate racks but does not necessarily mean separate rooms or cages.

C Material Control

1 Keep detailed perpetual inventory records on all orders, receipts, and issues, returns and excess materials.

2 Initiate Termination Inventory Schedules on obsolete, canceled, and terminated raw sheet stock.

II Manufacturing

A Production Planning

Provide special colored and stenciled Shop Order folders marked Magnesium-Thorium to identify that the detail parts are to be made from Magnesium-Thorium alloy.

B Production Project

1 Deliver Magnesium-Thorium materials with the color coded Magnesium-Thorium folder to DETAIL MANUFACTURING. Return all excess material larger than 8"x10" to RAW STORES.

2 Initiate Termination Inventory Schedules on obsolete, canceled, and terminated parts in process and completed assemblies.

3 Process cancellations on details and assemblies that are canceled by Engineering design changes.

4 Have all parts moved as an integral package - do not permit losses of material due to rejections, split folders, or other reasons.

C Manufacturing Engineering & Research

1 Flag all primary data sheets where there are detail parts to be made from Magnesium-Thorium.

2 Mark each page of the Process Planning Sheets in bold letters "MAGNESIUM-THORIUM".

3 Before each operation that will require removing material such as cuttings, chips or other residue, a step will be added to the process plan stating "clean machine and floor thoroughly before performing the next operation".

II-C (Cont'd)

4 After each operation that requires removing material such as cutting, chips, or residual remnant material, a step will be added to the process plan stating "clean machine and floor thoroughly and put all cuttings, chips, residual material in designated Magnesium-Thorium container".

5 A step will be included in the process plan requiring that all completed parts be identified with a Magnesium-Thorium identification spot.

D Factory

1 Handle Magnesium-Thorium in accordance with instructions in process plan, Safety Bulletins, and instructions of the Health Physics Representative.

2 Account for all material and parts as finished parts, rejected parts, scrap, or ofall.

E Conservation

1 Provide containers for Magnesium-Thorium material, cuttings, trimmings, clippings, and floor sweepings.

2 Store Magnesium-Thorium material until sufficient quantity is available for shipment to a designated scrap dealer.

3 Package the Magnesium-Thorium in containers to insure against loss.

4 Weigh all scrap and notify MATERIAL CONTROL of the weight of scrap sold.

NOTE: All rejected parts, scrap, ofall, or surplus materials will be kept separate from other materials and will be disposed of only to a licensed scrap dealer or in accordance with normal Government excess and surplus disposition procedure.

III Quality

A Inspect incoming material to assure that the proper quantity is received and material is identified as Magnesium-Thorium.

B Any portion of Magnesium-Thorium required for test purposes must not be disposed of in regular scrap material but must be returned to Magnesium-Thorium containers.

C Notify CONSERVATION whenever scrap is generated indicating the contract number involved.

IV Health Physics - Safety

A Monitor the handling of Magnesium-Thorium as required to assure prescribed safety measures are followed and that no health hazards exist. In particular, monitor all operations involving welding, grinding, polishing, etc., to insure that no harmful fumes or dusts are present in work areas.

B Monitor scrap metal containers to prevent accidental mixing of Magnesium-Thorium with other materials.

V Property Accountability

Process terminations and cancellations for Magnesium-Thorium as required.

FORMS USED

Termination Inventory Schedule A	-	Form 060830
Termination Inventory Schedule B	-	Form 060831
Termination Inventory Schedule C	-	Form 060832

THE MARTIN COMPANY
BALTIMORE 3, MARYLAND

DOCKET NO. 70-14 & 70-58

Mail No. M-722
Nuclear Division

filed

Director
Division of Licensing and Regulation
U. S. Atomic Energy Commission
Washington 25, D. C.

Attention: Mr. Joseph Delaney

Gentlemen:

Pursuant to Title 10 Code of Federal Regulations, Part 70 - SPECIAL NUCLEAR MATERIAL - amended November 11, 1958, we are submitting our plans for the installation of the radiation monitoring system and a description of our procedures for evacuating personnel in the event of any emergency.

I understand from the conversation between you and Joe Lockpert that we can expect your comments, probably in about a month, regarding the plans and procedures enclosed. Since it was requested that a tentative date for installing the system be submitted at this time, our estimate of time is based upon the receipt of your reply. Because the equipment to be employed is a Martin capital investment, amounting to a significant quantity, procurement action will be initiated as soon as we hear from your office. Allowing a maximum of 90 days for delivery plus an additional 30 days for installation and testing, it can be assumed that approximately four (4) months will elapse from the time of ordering equipment and materials to the time of accepted usage.

The enclosed floor plan shows the entire wiring scheme and the location of the currently planned stations. The receptacles, noted in red, are plug-in types which can accommodate one monitoring unit each.

For example, in the Waste Disposal Area work is performed only a few days per month. Any permanent station would therefore remain idle for the most part. Whenever work is to be performed in this area, a portable unit will be employed. By this means it will reduce our total inventory of monitoring units and allow flexibility in operations. Six permanent stations are currently planned with an additional two portable units to be used to monitor work in the areas where work is sporadic.

A/33

Enclosed is a listing of the units to be employed in the Manufacturing and Research Areas, and the Critical Facility Vault. We have not enclosed a plan for the Critical Facility. At the present time our test reactors are equipped, as required, with monitoring devices. The only additional coverage will be to install a unit in the Critical Facility Vault and include it in the circuit system now employed.

A copy of emergency procedures is also enclosed for your review and comment.

Very truly yours,

THE MARTIN COMPANY

/S/ F. G. Myers

F. G. Myers
Operations Manager

DOCKET NO. 70-14 & 70-58 (7) File

EMERGENCY PROCEDURES

I High radiation fields

Created as a result of a criticality incident or removal of an intense radiation source from a shielded to unshielded position.

A. Detected by observing the audible and visual alarms of the radiation monitoring equipment.

B. Personnel involved will:

1. Immediately leave the area taking advantage of all possible shielding and using nearest exit.

2. Notify Health Physics.

3. Keep other personnel from entering the area.

D. Health Physics will:

1. Establish the magnitude of the hazard by making appropriate instrument surveys.

2. Keep personnel at a safe distance from the source.

3. Check area for radioactive contamination.

4. Assist operating personnel in taking corrective action.

II High level spill

Created as a result of the breaking of a container of highly radioactive liquids or fine solids or as a result of an explosion, failure of ventilation system, etc.

A. The spill is detected by being observed by one or more operating personnel or by the audible-visual alarms of the radiation monitors.

B. Personnel involved in the spill will:

1. Leave the area and warn other personnel of the spill. If floor contamination is suspected, remove shoes to avoid spreading of contamination.

2. Call Health Physics.

3. Permit no one to enter the spill area until cleared by Health Physics.

DOCKETED USAEC Division of Licensing & Regulation OCT 6 1958 Docket Officer

C. Health Physics will:

1. Monitor the area to determine levels of contamination and to evaluate the potential hazards.

2. Establish the protective clothing that is needed and whether respirators should be worn.

3. Aid personnel in decontamination.

4. Determine the levels of radiation exposures and initiate urinalysis requests if internal exposures are suspected.

III Low level spills

Created by the dropping or breaking of a container of lowlevel radioactive liquids or solids or due to failures in ventilation system, fires, etc.

A. Detected by observation of operating personnel. May or may not be alarms from radiation monitoring equipment.

B. Personnel involved will:

1. Take immediate corrective action such as covering the spill with paper.

2. Leave the area taking precautions to minimize the spread of contamination.

3. Notify Health Physics.

4. Prevent other personnel from entering the area until cleared by Health Physics.

C. Health Physics will:

1. Establish the magnitude of the hazard.

2. Establish controls to prevent the spreading of contamination.

3. Assist in decontamination of personnel and equipment.

4. Determine the levels of radiation exposures and initiate urinalysis requests if internal exposures are suspected.

IV Air contamination

Created by fires, explosions, spills, failure in the ventilation system, etc.

A. Detected by the constant air monitors which give an audible and visual alarm. May or may not be alarms [illegible]

monitoring equipment in the area.

B. Personnel involved will:

1. Leave the area immediately and shut doors behind them.

2. Notify Health Physics.

3. Keep other personnel out of the area until cleared by Health Physics.

4. Decontaminate the entire area.

C. Health Physics will:

1. Evaluate the hazard and make recommendations concerning respiratory protection.

2. Aid operating personnel in finding the source of air contamination.

3. Establish controls to prevent the spread of contamination.

4. Aid in decontamination of personnel and equipment.

5. Determine levels of radiation exposures and initiate urinalysis requests if internal exposures are suspected.

V Fires involving radioactive materials

Fires of this type are divided into two categories:

A. Those that occur in areas containing low level sources and materials and,

B. Those that occur in areas containing high level sources and materials.

The procedures to be followed are as follows:

(A) Low level sources and materials:

These areas are all posted with a radiation sign reading, "CAUTION RADIOACTIVE MATERIALS";

1. Personnel involved will:

a. Notify fire department.

b. Attempt to extinguish fire by using approved fire fighting methods.

c. Avoid breathing of fumes or dusts created by the fire. Scott Air PAC respirators should be worn if air contamination is suspected.

d. Keep all personnel not needed to fight fire away from the scene.

e. Decontaminate area after fire is out.

2. Health Physics will:

a. Determine as quickly as possible the air contamination levels.

b. Check all personnel and equipment for contamination before they are permitted to leave the area.

c. Assist personnel in decontamination of area.

d. Determine levels of personnel exposures and initiate urinalysis requests if internal exposures are suspected.

(E) High level sources or materials:

These areas are all posted with a radiation sign reading, "CAUTION - RADIATION HAZARD".

1. Personnel involved will:

a. Notify Health Physics.

b. Notify fire department.

c. Attempt to extinguish blaze if there is good reason to believe that external radiation levels or air contamination levels are not excessive. Otherwise leave area immediately.

d. Keep all personnel away from scene except those needed to combat fire.

e. Decontaminate area after fire is out.

2. Health Physics will:

a. Determine radiation levels as quickly as possible. Stay with fire fighting crew until fire is out.

b. Determine contamination levels of entire area and of all fire fighting equipment.

c. Assist personnel in decontamination of area and equipment.

d. Determine levels of personnel exposures. If internal exposures are suspected, initiate urinalysis requests.

VI Emergencies during off shift hours

The outlined procedures will expedite emergency situations during off-shift hours by permitting firemen and others to safely enter certain areas without unnecessary and perhaps costly delays. The areas are identified as follows:

Radioactive Material Areas

These areas are identified by a 8" x 10½" magenta and yellow sign at each entrance reading RADIOACTIVE MATERIALS. The only conceivable way during off-shift hours of receiving an over-exposure to radiation in these areas is by breathing or swallowing dusts, fumes, or liquids, during such emergencies as a fire, an explosion, or failure in the ventilation system. Thus, the only protection needed by emergency personnel would be a Scott Air Pack, or similar type, respirator. Emergency personnel may enter these areas without waiting for the approval of the responsible supervisor. Emergency directors in each area will be notified by the Dispatcher after notifying emergency crews.

All personnel, before leaving these areas or removing any equipment following an emergency, must contact a Health Physics representative who will make any necessary contamination checks. These Radioactive Materials Areas are listed on the attached sheet.

Radiation Areas

These areas are identified by a 8" x 10½" yellow and magenta sign at each entrance reading RADIATION AREA. <u>These areas must not be entered by emergency personnel unless authorized by the responsible supervisor or a Health Physicist.</u> These areas are identified on the attached sheet.

All other areas not marked by one of the two signs above, will be free of radiation hazards and normal emergency procedures will apply.

EMERGENCY PROCEDURES IN AREAS CONTAINING RADIOACTIVE MATERIALS AND SOURCES

Radioactive Material Areas

1. Identified by a 8" x 10½" magenta and yellow radiation sign at each entrance reading "RADIOACTIVE MATERIALS".

2. May be entered in emergencies if Scott Air Pac or similar type respirators are worn. Respirators must be worn until the responsible supervisor or Health Physicist determines they are not needed.

3. Dispatcher must notify responsible supervisor after sending emergency crews to the scene.

4. Personnel must notify Health Physics before removing equipment or leaving the area.

5. Location:

   (1) The Nuclear Engineering Materials Laboratory and Pilot Plant Manufacturing Area, except for the Vault. Located in "D" building basement.

   (2) The Waste Room. This is an annex outside the south side of "D" building basement.

   (3) The Filter Room. This is an annex outside the south side of "D" building basement.

Radiation Areas

1. Identified by 8" x 10½" magenta and yellow radiation sign at each entrance reading "RADIATION AREA".

2. Must not be entered except on approval of the responsible supervisor or a Health Physicist.

3. Dispatcher must notify responsible supervisor immediately of any emergencies in these areas.

4. Personnel must notify Health Physics before removing equipment or leaving the area.

5. The door to all radiation areas are locked during "off shift" hours.

5. Location:

(1) The Vault. Located in the Pilot Plant Manufacturing Area.

(2) The test cell in the Radioisotopes Laboratory. Located in the SW corner of the "D" building basement annex.

(3) KC building or "C" test facility.

(4) The Gamma Pool. Located at column E-2, "D" building basement. The Gamma Pool has a special warning instrument outside the entrance door. A sign over the instrument explains how this area may be entered in the event of an intermittent alarm. If the Gamma Pool alarm sounds continuously, no entrance should be permitted without authorization from the responsible supervisor or a Health Physics representative.

DESCRIPTION OF MONITORING SYSTEM FOR

NUCLEAR FACILITIES (D BLDG.)

Nomenclature	Description
Basic Control Unit Victoreen Model 712	Provides power for up to 20 detector stations
Auxiliary chassis Victoreen model 713	Provides extra space for 6-10 detectors in addition to the 5 in the basic control unit
Scaling elements (detectors) Victoreen Model 716A	Gamma detectors Range 0.1 to 100 mr/hr built in calibration source. Logarithmic output, monitors 3 adjacent decades of radiation intensity on a single scale. Complete with audio-visual alarm
Sensing element (detector) Victoreen Model 716A	Gamma detector Range 1 to 10,000 mr/hr built in calibration source. Logarithmic output, monitors 3 adjacent decades of radiation intensity on a single scale. Complete with audio-visual alarm.
Plug in stations Victoreen Model 715B	Contains indicating and alarm meter, indicator light, remote calibration button. Should contain buzzer alarm.

AEC 318 (Rev. 9-53) GOVERNMENT PRINTING OFFICE 16—62701-3

THE MARTIN COMPANY

Baltimore 3, Maryland

January 16, 1959

DOCKET NO. 40-3296

U. S. Atomic Energy Commission
Division of Licensing and Regulation
Washington 25, D. C.

Attention: Mr. J. C. Delaney
Chief, Materials Section
Licensing Branch

Gentlemen:

I wish to acknowledge and thank you for your letter of January 7, 1959 relative to our procedures for handling and processing alloys of thorium-magnesium containing 4% or less thorium. While your letter very adequately covers the radiation safety aspect, we still have some concern with respect to the AEC's requirements for the maintenance of records.

As you know, the source material licenses covering these alloys require the licensee to maintain records of inventories and all receipts and transfers of refined source material. Insofar as I am aware, the AEC has not defined, with any greater particularity, the character of the records which are required for such material. In pursuance of the general requirement, our procedures do, of course, provide for the maintenance of strict records of the quantities of alloy procured and of the quantities disposed of as waste. At the same time we have, as explained in my letter to you dated December 1, 1958, found that it would be an extremely difficult and impractical task for us to maintain records of the quantities actually transferred in the form of fabricated items. However, we believe, and trust that you will agree, that such transfer records should not be regarded as essential, in our particular circumstances, because of the fact that all items fabricated by this Company which contain thorium-magnesium alloys are ultimately delivered to agencies of the Government.

In order that the matter may be clarified, I shall appreciate it if you will review the procedures previously submitted and let me know whether they satisfactorily meet the records requirements presently imposed by the applicable source material licenses. Please let me know if any additional information is desired.

STANDARD FORM NO. 64

Office Memorandum • UNITED STATES GOVERNMENT

DATE: Feb. 20, 1959

TO : Lyall Johnson, Chief, Licensing Branch
Division of Licensing and Regulation

FROM : Lester R. Rogers, Chief, Radiation Safety Branch
Division of Licensing and Regulation L.R. Rogers

SUBJECT: THE MARTIN COMPANY - DOCKET NO. 40-3296

The subject company has requested in their letter of January 16 that we review their accountability procedures for 4% thorium-magnesium alloy to determine if they meet the requirements of the condition of their source material license regarding record-keeping.

The Standard Procedures #44.43 dated November 17, 1958 appear to meet the requirements of the condition of license No. C-4283 regarding the maintenance of records of inventories, receipts, and transfer of refined source material. They had previously been advised that these procedures were satisfactory from the radiation safety standpoint. (Letter January 7, 1959).

As long as the company has records of receipt, and scrap disposal of thorium alloy, and the remainder is fabricated into missile components, records of the amount of thorium in each part and the total number of parts manufactured should not be required by the AEC. We would suggest, however, that records of transfer to various agencies be kept. It would seem as if this would be done in the normal course of business. Since only 4% alloy in fabricated parts is involved, a record of the names of the agencies to whom such transfers are made will probably be sufficient.

OPTIONAL FORM NO. 10

UNITED STATES GOVERNMENT

Memorandum

TO Lyall Johnson, Chief
Licensing Branch

DATE: March 16, 1960

FROM Charles D. Luke
Hazards Evaluation Branch

SUBJECT: MARTIN CO.

Re: February 9, 1960 application

The subject application included a revised manual. It is, of course, time consuming to review such a manual, when only a few changes from previously approved procedures are involved.

I talked with Mr. Fred Perella of Martin Co. here at Headquarters last week, and Mr. Lane and I spoke with Mr. Wm. Wachtel of Martin Co. by telephone today. Mr. Wachtel agreed to submit a list of specific changes from the previously approved procedures.

We will review these when received. No further action on Docket 70-58 is necessary at this time, and it is returned herewith.

Gentlemen:

It is requested that an appropriate amendment be issued to Byproduct Material License No. 19-1398-10A60 which will permit The Martin Company to transfer, own, and possess up to a maximum of 15 grams of irradiated Hastelloy C, in accordance with the provisions of Part 30 of Title 10 of the Code of Federal Regulations. In support of this request, we have completed and I am enclosing herewith three copies of AEC Form-313.

Please give me a call at MUrdock 7-3800, extension 595, if you desire any further information with respect to the enclosed application for amendment.

Very truly yours,

September 3, 1959

DOCKET NO. 40-3296

U. S. Atomic Energy Commission
Division of Licensing and Regulation
Washington 25, D. C.

Attention: Mr. J. C. Delaney
Chief, Materials Section
Licensing Branch

Gentlemen:

Pursuant to the provisions of Section 40.26 of the Code of Federal Regulations, Title 10 - Atomic Energy, Chapter 1, Part 40, The Martin Company hereby requests that Source Material License No. C-4283, dated September 15, 1958, be extended for a period of one year from September 30, 1959 to September 30, 1960.

We anticipate that we shall have to procure an additional 25,000 pounds of HK31A alloy during the one year period ending September 30, 1960. Accordingly, it is requested that said license be further revised to increase the amount of Thorium-magnesium alloy (containing not more than 4% Thorium) from 50,000 pounds to 75,000 pounds.

Very truly yours,

THE MARTIN COMPANY

Attention: Mr. Ross G. Macaulay

Gentlemen:

Pursuant to the Atomic Energy Act of 1954 and Section 40.21 of the Code of Federal Regulations, Title 10 - Atomic Energy, Chapter 1, Part 40 - Control of Source Material, you are hereby licensed to receive possession of and title to , at the above stated location, seventy-five thousand (75,000) pounds of thorium magnesium alloy containing not more than 4% thorium for fabrication.

You are further licensed to transfer and deliver possession of and title to refined source material to any person licensed by the Atomic Energy Commission, within the limits of his license.

As a condition of this license, you are required to maintain records of your inventories, receipts and transfers of refined source material.

This license is subject to all the provisions of the Atomic Energy Act of 1954 now or hereafter in effect and to all valid rules and regulations of the U. S. Atomic Energy Commission, including 10 CFR 20, "Standards For Protection Against Radiation."

Neither this license nor any right under this license shall be assigned or otherwise transferred in violation of the provisions of the Atomic Energy Act of 1954.

This license shall expire September 30, 1960.

Mr. R. G. Macaulay
Licensing Officer
The Martin Company
Baltimore 3, Maryland

Dear Mr. Macaulay:

We are enclosing License No. 19-1398-19 in response to your application of August 25, 1959.

We have not amended License No. 19-1398-10 to include this material as requested by your letter of August 25, 1959, because of our current policy of licensing the radiography use of byproduct material separate from other uses of by-product material.

Very truly yours,

Robert E. Brinkman
Senior Licensing Reviewer

Attention: Mr. James R. Mason, Chief
Isotopes Branch

Gentlemen:

It is requested that License No. 19-1398-10 heretofore issued to The Martin Company be amended to extend the expiration date and to reflect the changes noted in the enclosed form AEC-313.

Since License No. 19-1398-10 expires on January 31, 1960, it is requested that you extend the validity of the license for a period sufficient to allow your evaluation of the enclosed application. It is also requested that License No. 19-1398-19 be cancelled since the work involved in that license is covered in the enclosed application.

Enclosed, in triplicate, are AEC Forms 313 detailing the changes requested. Any additional information will be submitted upon request. You can contact me at MUrdock 7-3800 - Extension 8281 or 9668.

Very truly yours,

THE MARTIN COMPANY

Form AEC-313 (5-58)

'OMIC ENERGY COMMISSION

APPLICATION FOR BYPRODUCT MATERIAL LICENSE

Form approved. Budget Bureau No. 38-R027.3.

INSTRUCTIONS.—Complete Items 1 through 16 if this is an initial application. If application is for renewal of a license, complete only Items 1 through 7 and indicate new information or changes in the program as requested in Items 8 through 15. Use supplemental sheets where necessary. Item 16 must be completed on all applications. Mail three copies to: U. S. Atomic Energy Commission, Washington 25, D. C. Attention: Isotopes Branch, Division of Licensing and Regulation. Upon approval of this application, the applicant will receive an AEC Byproduct Material License. An AEC Byproduct Material License is issued in accordance with the general requirements contained in Title 10, Code of Federal Regulations, Part 30 and the Licensee is subject to Title 10, Code of Federal Regulations, Part 20.

1. (a) NAME AND STREET ADDRESS OF APPLICANT. *(Institution, firm, hospital, person, etc.)*

The Martin Company
Nuclear Division
Baltimore 3, Maryland

(b) STREET ADDRESS(ES) AT WHICH BYPRODUCT MATERIAL WILL BE USED. *(If different from 1 (a).)*

Radioisotope Laboratory, "D" Bldg.
Middle River, Maryland
(Radiograph Room)

2. DEPARTMENT TO USE BYPRODUCT MATERIAL

Materials Service Unit,
Nuclear Components Department

3. PREVIOUS LICENSE NUMBER(S). *(If this is an application for renewal of a license, please indicate and give number.)*

19-1398-10

4. INDIVIDUAL USER(S). *(Name and title of individual(s) who will use or directly supervise use of byproduct material. Give training and experience in Items 8 and 9.)*

C. E. Hollens

5. RADIATION PROTECTION OFFICER *(Name of person designated as radiation protection officer if other than individual user. Attach resume of his training and experience as in Items 8 and 9.)*

Richard H. Boutelle
(Resume previously submitted)

6. (a) BYPRODUCT MATERIAL. *(Elements and mass number of each.)*	(b) CHEMICAL AND/OR PHYSICAL FORM AND MAXIMUM NUMBER OF MILLICURIES OF EACH CHEMICAL AND/OR PHYSICAL FORM THAT YOU WILL POSSESS AT ANY ONE TIME. *(If sealed source(s), also state name of manufacturer, model number, number of sources and maximum activity per source.)*
A. Ir^{192}	Sealed sources, Technical Operations Inc., Model A424 - 62 curies max., 31 curies/source max.
B. Sr^{90}-Yt^{90}	Sealed sources, Tracerlab model RA-2 150 millicuries max. Tracerlab model S-1 - 150 millicuries/source max.
C. Co^{60}	Sealed sources, Technical Operations, Inc., Model A-424 10 curies max., 5 curies/source max.
D. Tm^{170}	Sealed Sources, Technical Operations, Inc., Type A capsules, 120 curies max., 60 curies/source max.
E. Any byproduct material between Atomic #3 and 83 inclusive.	Irradiated metal samples, 2000 millicuries max. total of byproduct material between Atomic Nos. 3 & 83 inclusive.

7. DESCRIBE PURPOSE FOR WHICH BYPRODUCT MATERIAL WILL BE USED. *(If byproduct material is for "human use," supplement A (Form AEC-313a) must be completed in lieu of this item. If byproduct material is in the form of a sealed source, include the make and model number of the storage container and/or device in which the source will be stored and/or used.)*

(A) Ir^{192} to be used in Technical Operations Model 412 projector for industrial radiography at the Martin Plant, Middle River; (B) Sr^{90}-Yt^{90} to be used for instrument calibration and for research and development programs in the radioisotope laboratory. (C) Co^{60} to be used in Technical Operations Model 402 projector for industrial radiography at the Martin Plant, Middle River; (D) Tm^{170} to be used for instrument calibration and for research and development programs in the radioisotope laboratory. (E) Atmoic Nos. 3 & 83 inclusive - experimental tool wear studies and sea water corrosion tests conducted in the radioisotope lab.

FOR DIV OF INSP

23795

Question No. 11 - Method, Frequency, and Standards used in calibrating instruments listed above (Question 10)

Calibration of Health Physics survey instruments is performed in the Calibration Facility located in the Waste Storage Room outside the Nuclear Manufacturing and Engineering Laboratories at Plant No. 1. Each instrument is calibrated once a month. Repaired instruments are calibrated when they are returned to Health Physics.

The sources are located in one corner of the Waste Room behind a four foot high, eight-inch thick, cement block wall. A one curie Co-60 source contained in a lead-steel shielded container is used for calibrating "Cutie-Pie" and similar type instruments.

The source is calibrated so that at given distances the dose rate in mr/hr is known. The instrument can be remotely placed at a given distance from the source and calibrated to read the field of radiation at that distance. Where possible, each instrument is calibrated on each scale or range setting.

Smaller sources include an eight millicurie Co-60 source and a one millicurie Ra-226 source. These are also stored behind the shielding wall and used to calibrate low range (up to 20 mr/hr) instruments.

Neutron survey instruments are calibrated by using a five curie Po-Be neutron source of known flux (determined by foil activation) and setting the instrument to read the correct level.

Counting room instruments are calibrated by using standard calibrated sources of uranium alpha and beta-gamma. The first step is construction of a "plateau" to determine correct operating voltages. The counter efficiency is then determined by comparing the counter countrate with that of the standard source.

23705

Question No. 12 - Film Badges, Dosimeters, and Bio-Assay Procedures Used.

A. General:

All personnel working with radioactive materials permanently or temporarily, are required to wear a film badge and two pocket chambers sensitive to beta-gamma radiation.

Personnel working in areas where fast and/or thermal neutron radiation is prevalent are required to wear a film badge sensitive to beta, gamma and fast neutrons and pocket chambers sensitive to thermal neutrons.

Film badges are changed either weekly, biweekly, or each 13 weeks depending upon the radiation levels in the work areas. Pocket chambers are changed and read daily. Self-reading dosimeters are also available and used under the discretion of Health Physics.

A film badge service is contracted on a yearly basis to supply and process film and badges for the program. The present supplier is Health Physics Services, Baltimore, Maryland

B. Dosimetry Information:

Special film badge changes are made by Health Physics when any of the following conditions exist:

(1) Both pocket chambers off scale.

(2) Exposure in excess of 100 mr/wk is recorded from daily pocket chamber readings.

(3) Inexplicable exposure in excess of 50 mr per day is recorded.

Permanent records are maintained of all film badge and pocket chamber results.

The upper limit of dosimetry response is as follows:

FILM BADGES	UPPER LIMIT (rem)
Gamma	1000
Beta	500
Neutrons	100
POCKET CHAMBERS	
Gamma	200 mr
Neutrons	200 mrem

23735

(Question No. 12 - Cont'd.)

C. Bioassay

All facility personnel are required to submit bioassay samples at periodic intervals. In the case of unusual incidents, including exposure to airborne concentrations of radioactive materials exceeding the maximum permissible concentrations for personnel without respiratory protection, or other suspected ingestion of radioactive material, special samples are collected from all personnel involved.

All urinalysis results are filed as permanent records in the Health Physics office and are available to responsible persons upon request.

23795

Question No. 14 - Radiation Protection Program

A. Health Physics Responsibilities:

1. Plans and administers the radiation protection program to provide adequate protection to Company and to personnel from ionizing radiation.

2. The inspection and monitoring, with the aid of various detection instruments, of personnel, machinery, furniture, ventilating equipment, gamma and neutron irradiation test facilities, radioisotopic laboratories, etc., to detect and prevent spread of radioactivity, measure levels of radiation or concentrations of radioactive materials present.

3. The review and approval of all working areas and facilities.

4. The evaluation of radiation hazard control methods for adequacy and compliance with recommendations of the National Committee on Radiation Hazards and pertinent government regulations.

5. The promotion of the Health Physics program through the proper indoctrination and training of personnel engaged in handling or working with materials or equipment that emit ionizing radiation.

6. Determines radiation monitoring equipment requirements in all areas.

7. The internal control and enforcement of licensing regulations pertaining to receiving, possession, use, transfer and disposal of nuclear source, special nuclear, or by-product materials.

8. The investigation of accidents and personnel radiation exposures to determine the cause and recommend corrective action to be taken to eliminate future occurrences.

9. The continual monitoring of personnel engaged in handling or working with radioactive materials and x-ray equipment for compliance with recommended procedures and regulations of good housekeeping and work habits.

10. The issuance of appropriate personnel monitoring devices (film badges, pocket chambers, etc.), scheduling of pre-exposure and follow-up physical examination, and the establishment and maintenance of detailed employee records of cumulative doses of radiation exposure, biological assays, laboratory reports, etc., to form the basis of permanent Company records and to conform to Atomic Energy Commission regulations.

11. The conducting of laboratory tests of environmental sample analyses and biological assays to determine the quantity of radioactivity disdharged to the environs and the quantity received by the individual through inhalation, ingestion, wounds, etc.

22795

Question 14 - Cont'd.

12. Collaborates with representatives of the various divisions and departments concerned on reactor site surveys, design of facilities, power reactors and associated control systems for hazard evaluation and control to assure protection of personnel and facilities.

13. Maintains liaison with representatives of the Atomic Energy Commission, National Committee on Radiation Hazards, Federal, State and Local government health and welfare agencies, and various divisions and departments, to resolve areas of common health physics interest.

14. Prepares and revises as necessary Health Physics bulletins outlining procedures to be followed to assure compliance with all pertinent National Committee or radiation hazards recommendations and government regulations.

15. The calibration of all Health Physics monitoring instruments where radiation sources must be used to perform the calibration.

B. Leak Testing

Leak tests are performed on all sealed sources when they are received and at least once every three months thereafter. The source, or source shield depending upon the strength of the source, is wiped with a filter paper disc. The disc is then counted in the proper radiation counter to detect and measure any leakage of alpha or beta-gamma contamination.

Radium sources are leak tested by wrapping the source in cotton for approximately three days, removing the cotton and counting it with a beta-gamma detector.

Leak tests are performed by Health Physics technicians who have had three years of on-the-job Health Physics training with The Martin Company.

Maintenance, service and repairs to all sources are performed by the source supplier.

C. See also supplementaty report MND 2109.

23795

Question No. 15 - Waste Disposal

Solid waste is currently stored in 55 gallon steel drums awaiting disposal through an AEC approved, licensed waste disposal service. A record is maintained by Health Physics concerning the contents, radiation and number of each drum.

Liquid waste is monitored to assure that the levels of radioactivity are below the tolerances established in Title 10, Part 20 Code of Federal Regulations for disposal into sanitary sewers. All liquid waste with activity above those levels is evaporated and concentrated for eventual solid waste disposal through AEC approved and licensed waste disposal services.

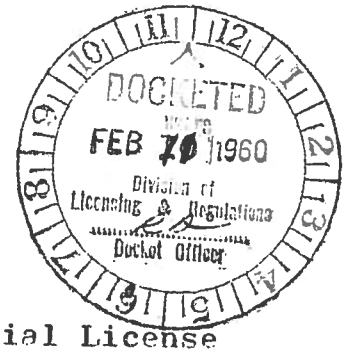
Refer to: NMC-5

Director
Division of Licensing and Regulation
United States Atomic Energy Commission
Washington 25, D. C.



Attention: Mr. Lvall Johnson
Chief, Licensing Branch

Gentlemen:

Reference is made to our Special Nuclear Material License SNM-53 as amended. We desire to further amend this license in order that we can (1) proceed to fabricate an additional element type not previously described and (2) receive and use a Plutonium-Beryllium neutron source in connection with our critical facility experiments.

Accordingly, we wish to add to Appendix B of our License application the process description and SN material flow chart, Attachment (1).

The Plutonium-Beryllium source will be used to supply neutrons for starting the ERDL critical assembly and it is anticipated that it will be kept by The Martin Company for an indefinite period of time for use in other critical experiments. For details on the Martin Critical Facility see reports MND-1110, 1111, 1112 and MND-E-1157.

The source consists of Beryllium intimately mixed with Plutonium and seal welded in an inner tantalum capsule. This inner capsule is in turn welded in an outer capsule of stainless steel whose dimensions are 1.55 inch diameter by 3.4 inch length. The source contains 160 grams of Plutonium isotope 239. Reference the Mound Laboratory catalog of Polonium and Plutonium sources, November 1, 1959, pages 24 through 26.

The source will be stored in the original shipping container and kept in a controlled area until it is installed in the source shield in the critical assembly tank. The source

A/44

will be raised to operating position for start-up of the assembly. Swipe tests will be performed no less frequently than once once every three months. The Martin Company has been using a Polonium-Beryllium Source as covered under License Number 19-1398-1.

Since there have been revisions in our facilities and handling of SNM materials we are enclosing the latest revised copy of our Criticality Manual, MND-1063, revised as of February 1, 1960. Please return our Criticality Manual that you now have in your possession.

I certify that the statements made in this letter and the referenced enclosures are true, complete and correct to the best of my knowledge and belief, and are made in good faith.

Very truly yours,

THE MARTIN COMPANY

J. V. Lonnert
Operations Manager

ALUMINUM CLAD [illegible]-ZIRCONIUM ALLOY FUEL PLATE UNIT ELEMENTS
(Part VI-c)

A predetermined quantity of uranium metal (enrichment range 5 to 20 weight percent) and [illegible] are melted in Work Area 33. A billet is then formed and hot rolled (Work Area 17) into a billet approximately 1/4 inch thick. Fuel cores are punched (Work Area 35) from the billet, and identified. The fuel cores are then reassembled into cladding (picture frames) and hot rolled to a reduction of about 90 percent. Aluminum cladding sheets are tack welded on each side of the pre-rolled core and the elements are reduced to final size causing bonding to occur between the aluminum cladding and the uranium-aluminum core. Radiography, non-destructive testing and blister-annealing are done in Work Areas 23, 25 and 27 respectively. The fuel plates are assembled into fuel elements in Work Area 41.

Attention: Mr. Lyall Johnson
Chief, Licensing Branch

Reference: (a) Amendment dated February 9, 1960 to License SNM-53
(b) Criticality Precautions Manual, revised February 1, 1960

Gentlemen:

In order to assist you in reviewing our Amendment, Reference (a), we are submitting the following information which outlines differences in the Criticality Precautions Manual in your possession and the revised manual, Reference (b).

2.002.0 Approach to Problem

The procedure for making additions to the manual is clarified. Work description and allowable limits for each fuel element process and associated work areas will be prepared as Appendicies to the basic manual.

2.003.0 Enforcement

Responsibility for enforcing criticality procedures now lies with the accountable person, i.e. Accountability Representative, Facility Supervisor or designee.

2.004.0 Means of Control

Paragraphs 2.004.2 and 2.004.3 are revised in the referenced manual.

A/48

2.005.0 Emergency Procedures

Health Physics emergency procedures have been removed from the referenced manual, however, Health Physics procedures outlined in the original manual are still applicable.

2.006.0 Procedures for Fuel Element Development and Manufacture

Description of Facilities - Current manufacturing and engineering shop arrangements and criticality areas are presented in Figures 1 and 2 in the referenced manual.

Allowable Limits for Work Areas - Additional material forms have been added to the Table of Allowable Limits for Work Areas as follows: Ib, IIc, IId, IIe, IIf, IVb, VIc, VIIIc and XIb. Forms IX and X are redefined.

Storage Containers - Three additional types of storage containers have been added as follows: ERDL Foil Containers; PM-1 Fuel Element Containers; Inserts for ANPP Fuel Element Storage Containers.

Procedures for Special Work Areas - Work area descriptions as applicable to specific projects have been deleted. Descriptions of general procedures are given as follows in the referenced manual:

	Paragraph
Receipt and Storage	2.006.4
Issuing of Special Nuclear Material	2.006.5
Transfer of Nuclear Materials	2.006.6
Transport Lanes	2.006.7
Shipping	2.006.8
Procedures for Specific Work Areas	2.006.9

2.007.0 Procedures for Critical Experiment Facilities

Work area 105, Counting Room, was added.

2.008.0 References

Additional references given in the referenced manual include:

TID-7016 - Nuclear Safety Guide
TID-7019 - Guide to Shipment of U-235 Enriched Uranium Materials

Refer to: NMC-109

cy this request sent Inspection 3/30/60

Director
Division of Licensing and Regulation
United States Atomic Energy Commission
Washington 25, D. C.

Reference: Our letter NMC-5 dated February 9, 1960

Gentlemen:

In the referenced letter we applied for an additional amendment to our Special Nuclear Material License, SNM-53. Due to certain misunderstandings which have held up approval of this amendment we request that the referenced application be replaced by this letter.

We desire to amend License SNM-53 in order that we can (1) proceed to fabricate uranium-aluminum alloy fuel elements and (2) receive and use a Plutonium-Beryllium neutron source in connection with our critical facility experiments.

Since our License as it currently stands does not cover fabrication of uranium-aluminum alloy fuel elements, we are enclosing a report, MND-2330, which covers the Nuclear and Health Safety aspects of this fabrication.

The Plutonium-Beryllium source will be used to supply neutrons for starting the ERDL critical assembly and it is anticipated that it will be kept by The Martin Company for an indefinite period of time for use in other critical experiments. For details on the Martin Critical Facility see reports MND-1110, 1111, 1112 and MND-E-1157.

The source consists of Beryllium intimately mixed with Plutonium and seal welded in an inner tantalum capsule. This inner capsule is in turn welded in an outer capsule of stainless steel whose dimensions are 1.55 inch diameter by 3.4 inch length. The source contains 160 grams of Plutonium isotope 239. Reference the Mound Laboratory catalog of Polonium and Plutonium sources, November 1, 1959, pages 24 through 26.

A/49

THE MARTIN COMPANY

Baltimore 3, Maryland

The source will be stored in the original shipping container and kept in a controlled area until it is installed in the source shield in the critical assembly tank. The source will be raised to operating position for start-up of the assembly. Swipe tests will be performed no less frequently than once every three months. The Martin Company has been using a Polonium-Beryllium Source as covered under License Number 19-1398-1.

I certify that the statements made in this letter and the referenced enclosures are true, complete and correct to the best of my knowledge and belief, and are made in good faith.

Very truly yours,

THE MARTIN COMPANY

NUCLEAR AND HEALTH SAFETY
CONTROLS FOR FABRICATION OF
URANIUM-ALUMINUM FUEL PLATES

March 23, 1960

DOCKETED
USAEC
Division of
Licensing & Regulation
1960
Docket Officer

INTRODUCTION

This report outlines nuclear material control requirements for the fabrication of uranium-aluminum alloy fuel elements as described below. Two cores consisting of 46 fuel elements 11 fuel plates each, are planned to be fabricated. The total feed requirement is approximately nine kilograms of 93 % enriched uranium metal. The process involves alloying uranium and aluminum, hot rolling the ingots to one-quarter inch slabs and punching fuel core slugs. These core slugs are then pressed into aluminum picture frames and hot rolled. Cladding of 1100 aluminum will then be applied, followed by further hot and cold rolling to achieve bonding. Each fuel plate will contain 13.2 ± 1.0 grams of U-235. The anticipated final scrap consists of uranium aluminum alloy and will include approximately 10% of the feed material.

The table below shows the form of uranium to be utilized in the process and the allowable limits. These limits are based upon the theoretical limits for the form calculated using the optimum mixture of water and fuel bearing aggregate and based on Appendix A of NMD-1053. These limits are conservative with respect to recommendations presented in TID-7016 (Nuclear Safety Guide) and TID-7029 (Guide to Shipment of U 235 Enriched Uranium Materials).

Form	Limits U-235
(1) Uranium metal in fine cuttings, dust, etc.	500 gms
(2) Uranium-Al alloys in this form	700 gms
(3) Uranium-Al alloy clad shapes in this form	500 gms
(4) Uranium in aqueous solutions	2 gms/liter

Total quantities will be kept under 350 grams

The actual quantities of U 235 used in the process below will fall under the above theoretical limits.

Reject plates will be chemically milled (etched) in 170 liters caustic solution. A maximum of 24 plates will be etched at one time (equivalent of 338 grams U-235). The plates will be under-etched leaving about 2 mils of aluminum cladding on the core. However, samples of the caustic solution will be taken after each batch to determine uranium content. Should all the plates in one batch dissolve in the caustic solution the maximum concentration would be less than two grams per liter.

Storage and shipping of scrap and finished fuel elements will be covered in a forthcoming amendment.

HEALTH PHYSICS AND INDUSTRIAL HYGIENE

A. Health Physics

The entire manufacturing operation will be conducted under the surveillance of the Health Physics Section of the Employment and Personnel Department.

Specific health physics requirements for each operation are contained in the Nuclear Materials Control Manual issued for the program. All processes will be surveyed by Health Physics Section to insure compliance with standards of 10 CFR 20 or better in all aspects.

B. Industrial Hygiene

Safety and industrial hygiene services at The Martin Company are handled by the Safety Section of the Security Division of The Martin Baltimore Division. This Section provides various safety and industrial hygiene consulting services, specified equipment and approved processes for all operations not involving radioactive material. The following precautions will be taken throughout the process in order to maintain safe working conditions for personnel involved in the manufacturing of fuel elements:

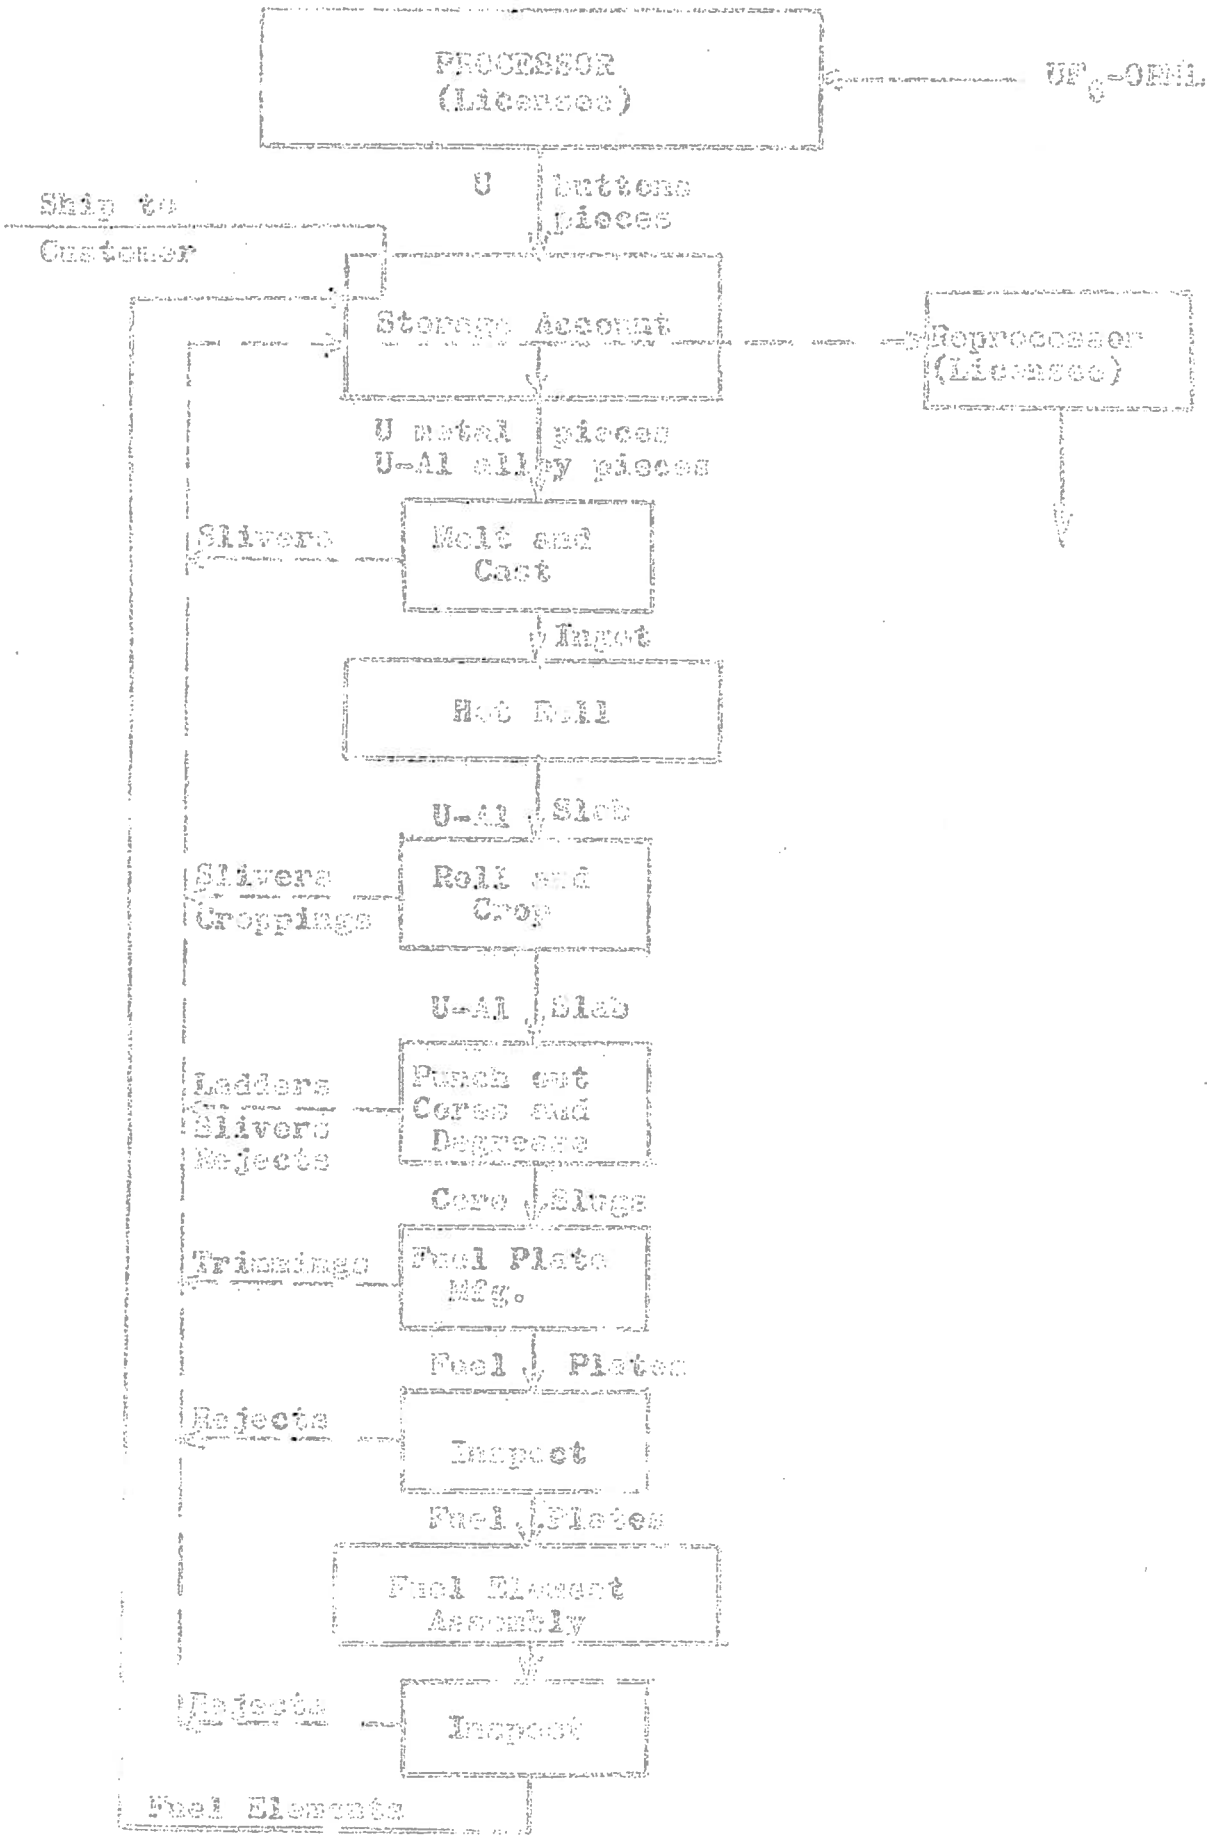
1. Ventilation will be provided for all operations involving hazardous vapors if necessary.

2. Personnel protective equipment, including acid resistant rubber gauntlets, aprons, acid type goggles and approved respirators, will be worn during all cleaning and degreasing operations. Similar equipment, with the addition of heat resistant gloves, will be worn during aluminum melting operations.

3. Processes and equipment will be evaluated prior to being put into operation to insure the incorporation of necessary safety and health precautions.

4. All operations will be surveyed routinely and any corrective action taken as needed.

S. MATERIAL & MANUFACTURING FLOW CHART



STORAGE BIRD CAGE

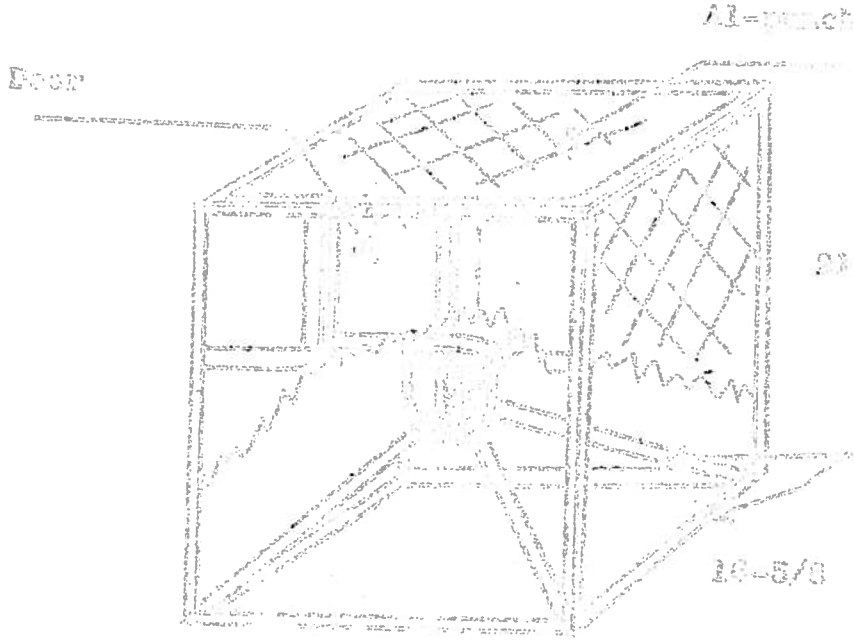


Figure 9

The birdcage for storing and transporting mealing parakeets is a skeletal box-like device, a cavity for holding the SS material. The birdcage is of welded aluminum construction. The birdcage is 16-5/8 inches by 16-5/8 inches by 21-3/8 inches high. The cavity is 4-1/4 inches in diameter by 6-3/4 inches deep and is situated so as to provide 4 inches from its outer diameter to the sides, front, rear and bottom of the birdcage and 10-1/2 inches to the top of the birdcage.

The containers for powder, border blends and broken kernels are constructed of 1/16 inch stainless steel and are smooth, spherical bottomed cylinders with flat screw type stainless steel covers capable of effecting an airtight seal. The smaller cylindrical container is 3-7/16 inches inside depth by 2 inches inside diameter with a 1 inch inside spherical radius bottom. The larger cylindrical container is 5-15/16 inches inside depth by 3-3/16 inches inside diameter with a 2.062 outside spherical radius bottom.

Containers for holding fuel tubes, fuel plates and other SS fuel materials are 12 inches by 12 inches or 12 inches by 15 inches and vary in length from 30 inches to 36 inches. These are of welded aluminum construction to facilitate handling. Handling eyelets of [illegible] are provided to hold the SS feed material, [illegible] and flat-head pullout.

Stock scrap is generated at [illegible] Company, Nuclear Materials [illegible] and [illegible] Mallinckrodt (as described [illegible]) [illegible] [illegible] [illegible]

STORAGE VAULT

As discussed in MID-1003, the storage vault is a fully enclosed room, 22 feet 6 inches long by 15 feet 9 inches wide and 11 feet high. Walls are nine inches thick and made of reinforced concrete. Ceiling and floor will be of the same construction. Sole entrance to the vault is through a 1/2 inch solid stainless steel door equipped with an approved combination lock. There are no water conduits or other service piping or drains within the vault.

The storage cartridges will be stored along three walls of the vault in a pile array. The lowest rows are placed on platforms about 12 inches above the floor to decrease the probability of flooding. Storage racks for fuel elements are located in the center of the vault. An aisle with a minimum width of 3 feet separates these racks from bird-cage array along the walls.

CORE SLAB SAMPLING PROCEDURE

SAMPLING PROCEDURE

Each slab will have 9 specimens, (numbered 1 to 9) punched in the areas shown on the attached, "Slab Sampling Plan".

Specimens 1, 2, 3, 4, 5 and 6 will be chemically analyzed individually for uranium content.

Specimens 7, 8 and 9 from the core area will be chemically analyzed together.

A permanent record of each slab as split based on above information will be maintained.

OPTIONAL FORM NO. 10

UNITED STATES GOVERNMENT

Memorandum

TO : Lyall Johnson, Chief
Licensing Branch

DATE: March 25, 1960

FROM : Clifford K. Beck, Chief
Hazards Evaluation Branch

SUBJECT: MARTIN CO.

We have reviewed the Martin application dated March 23, 1960, describing a process for the fabrication of uranium-aluminum fuel elements.

The proposed operations include receiving and storage of raw materials, melting and casting of the uranium-aluminum alloy, hot rolling, cropping and punching, final rolling and trimming of the fuel plates and assembly into fuel elements. Rejected fuel plates will be etched in caustic to remove most of the aluminum cladding, after which the material will be recycled to the melting operation. Shipping of the scrap and finished fuel elements will be covered in a subsequent amendment.

Martin proposes to insure safety from criticality by limiting the mass of U-235 in each individual work area and, in the case of solutions by limiting U-235 concentration to 2 g/liter. A maximum of 500 g U-235 will be charged to each casting operation. During subsequent processing steps the maximum U-235 handled in any operation (work area) will be limited to 700 or 800 g U-235 in the uranium-aluminum alloy. Uranium aqueous solutions will be limited to a maximum of 350 g U-235 in any batch and also the concentration will be limited to 2 g U-235/liter. During the etching process the U-235 in the caustic solution will be limited so that if all 24 plates being etched in one batch were to be completely dissolved in the caustic solution the maximum U-235 concentration would be less than 2 g/liter. Batches of dry scrap will contain a maximum of 500 g U-235.

Vault storage procedures have been previously approved in connection with the basic application. However, we have again reviewed vault dimensions and storage arrays and believe that there is no undue risk of criticality in the storage vaults.

We believe that the mass limits and concentration controls proposed by Martin are conservative. Consequently, we recommend approval of the application amendment.

UNITED STATES GOVERNMENT

Memorandum

TO : Files

DATE: March 30, 1960

FROM : J. J. Lane

SUBJECT: THE MARTIN COMPANY REQUEST DATED FEBRUARY 9, 1960 AS AUGMENTED MARCH 23, 1960 FOR AMENDMENT TO THEIR SPECIAL NUCLEAR MATERIAL LICENSE SNM-53 - DOCKET NO. 70-58

ANALYSIS AND FINDINGS

An analysis of the subject application for amendment to their special nuclear material license has resulted in the following observations, conclusions and findings.

The applicant requests that it be authorized to receive, possess and use one hundred sixty (160) grams of Pu-239 for the starting of their ERDL critical assembly and other critical experiments, and to fabricate uranium - aluminum fuel elements. The proposed use of the special nuclear material is for the conduct of research and development activities of the type specified in Section 31 of the Act.

Based on our review of the information furnished by the applicant, it is hereby determined that the applicant is qualified by reason of training and experience to use the special nuclear material for the purpose requested and that the applicant's proposed procedures, facilities and equipment are adequate to protect health and minimize danger to life and property. The applicant's procedures to avoid a condition of accidental criticality are adequate.

The application contains adequate corporate data.

It is, therefore, determined that the application meets the requirements of the Act and the regulations of the Commission and that the license may be amended to authorize the additional activities proposed, and that the required allocation may be granted.

UNITED STATES
ATOMIC ENERGY COMMISSION

SPECIAL NUCLEAR MATERIAL LICENSE

Pursuant to the Atomic Energy Act of 1954 and Title 10, Code of Federal Regulations, Chapter 1, Part 70, "Special Nuclear Material Regulations," a license is hereby issued authorizing the licensee to receive and possess the special nuclear material designated below; to use such special nuclear material for the purpose(s) and at the place(s) designated below; and to transfer such material to persons authorized to receive it in accordance with the regulations in said Part. This license shall be deemed to contain the conditions specified in Section 70.32(a) of said regulations, and is subject to all applicable rules, regulations, and orders of the Atomic Energy Commission now or hereafter in effect and to any conditions specified below.

Licensee

1. Name **The Martin Company**

2. Address **Baltimore 3, Maryland**

3. License No. **SNM-53, as amended**

4. Expiration Date **April 30, 1963**

5. Docket No. **70-58**

6. Special Nuclear Material

Uranium enriched in the U-235 isotope, and plutonium.

7. Maximum quantity of special nuclear material which licensee may possess at any one time under this license **500 kgs U-235 contained in uranium enriched in the U-235 isotope as UO_2 and metal, and 160 grams Pu-239 as a Pu-Be neutron source.**

8. Authorized use: **For the development and fabrication of reactor fuel elements in accordance with the procedures described in the licensee's application dated Oct. 11, 1956, as amended Oct. 24, 1956, and as amended by amendments executed Dec. 6, 1957; Jan. 15, 1958 and March 23, 1960.**

9. Quantity of special nuclear material allocated to licensee pursuant to Section 70.31(b) of said part

0.16 kg Pu-239 encapsulated as a Pu-Be neutron source.

CONDITIONS

10. Unless otherwise specified, the authorized place of use is the licensee's address stated in Item 2 above.

Place of Use: Licensee's Middle River Plant, Maryland

Mail No. W-756
May 3, 1960

U.S. Atomic Energy Commission
Division of Licensing and Regulation
Washington 25, D. C.

Attn: Mr. James R. Mason, Chief
Isotopes Branch

Gentlemen:

It is requested that Byproduct Material License No. 19-1398-19 be amended as follows:

Item 8A - Change maximum amount of radioactivity to read: Two sources not to exceed 50 curies per source.

This change is requested to permit use of a 50 curie Iridium 192 source in the Technical Operations, Inc. Model 412 projector. It is understood that the manufacturer of this projector has filed specifications with your office and that the use of the projector with a 50 curie source will conform to standards of Title 10 CFR Part 20.

Should you require any further information contact me or Mr. Richard H. Boutelle, X-9517-8.

Very truly yours,

THE MARTIN COMPANY

J. V. Loppert

Gentlemen:

Pursuant to the Atomic Energy Act of 1954 and Section 40.21 of the Code of Federal Regulations, Title 10 - Atomic Energy, Chapter 1, Part 40 - Control of Source Material, you are hereby licensed to receive possession of and title to, at the above stated location, one hundred thousand (100,000) pounds of thorium magnesium alloy containing not more than 4% thorium for fabrication.

You are further licensed to transfer and deliver possession of and title to refined source material to any person licensed by the Atomic Energy Commission, within the limits of his license.

As a condition of this license, you are required to maintain records of your inventories, receipts and transfers of refined source material.

This license is subject to all the provisions of the Atomic Energy Act of 1954 now or hereafter in effect and to all valid rules and regulations of the U. S. Atomic Energy Commission, including 10 CFR 20, "Standards For Protection Against Radiation."

Neither this license nor any right under this license shall be assigned or otherwise transferred in violation of the provisions of the Atomic Energy Act of 1954.

This license shall expire September 30, 1960.

Memorandum

TO : Lyall E. Johnson, Chief
Licensing Branch

DATE:

FROM : Clifford K. Beck, Chief
Hazards Evaluation Branch CKB

SUBJECT: MARTIN COMPANY

We have reviewed the Martin Company application dated April 18, 1960, requesting approval of procedures for shipping fuel elements.

Martin proposes to ship four aluminum clad elements (156 g U-235 each, 624 g total) per container. Each fuel element will be enclosed in corrugated cardboard, and the four elements will be packed in a 6" x 7" x 28" wood box which is supported in the center of a 55 gallon steel drum by means of plywood supports. Any one shipment (to either the University of California or the University of Washington) will comprise a maximum of six containers (24 elements, 3.74 kg U-235).

We recommend approval of the shipping containers, on the basis of acceptable mass per unit and spacing between individual units, which would protect against accidental criticality in case the array is wetted or flooded.

The actual shipping procedures are not described in the application. We request further information on the mode of shipment, including applicant's arrangements to insure that his material will not be brought into proximity enroute with other shipments of special nuclear material.

Info on shipping given to Wachtl on 6/13/60 (office visit. Martin will submit the additional info. JJS

Licensing Branch

Gentlemen:

Reference is made to our Special Nuclear Material License SNM-53 as amended. Under a recent amendment dated 4/5/60 The Martin Company was authorized to receive and use 0.16 Kg Pu-239 encapulated as a Pu-Be neutron source. We request to further amend this license to receive and use a Plutonium-Alpha Source.

The requested Pu-Alpha Source will be used by our Health Physics Section for instrument calibration purpose. The use, restrictions and proposed health-safety precautions are attached to this request.

The Pu-Alpha Source is a Mound Laboratory Catalog Item No. IX-B (Mound Laboratory Catalog of Polonium and Plutonium Sources, November 1, 1959, pages 22, 23 and 24). The source will consist of no more than 0.7 milligrams (10^8 disintegrations per minute) deposited in the form of PuO_2 on stainless steel. The stainless steel plate is a circular disk, 1/8 inches thick by two (2) inches in diameter. The PuO_2 is deposited in a un-sealed well 0.02 inches deep by one (1) inch in diameter.

I certify that the statements made in this letter and enclosure are true, complete and correct to the best of my knowledge and belief and are made in good faith.

Very truly yours,

THE MARTIN COMPANY

Plutonium Handling - Unclad - Procedure

This unclad, Pu source will be used by members of the Health Physics Section to calibrate alpha counters. It will be handled with tongs and when not in use will be stored in a metal container and placed in a wooden source holder. When handling, care will be taken not to scratch the source surface.

Procedure:

1. Keep source in container when not in use.
2. Use tongs to handle source, never bare hands as it is unclad.
3. Do not scratch source surface.

Gentlemen:

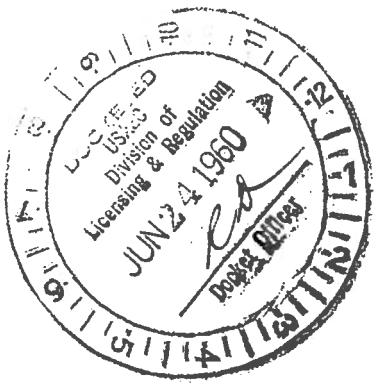
Reference is made to our Special Nuclear Material License SNM-53 as amended. On January 26, 1959, you sent a letter to the Martin Company amending our License by adding the following item:

> "Item 10: Unless otherwise specified, the authorized place of use is the address stated in Item 2 above. Authorized place of use, the licensee's plant at Middle River, Maryland. As a further condition of this license, the licensee shall, within 120 days of the date of this letter, comply with the provisions of his application filed with the Commission December 16, 1958 regarding the plans for compliance with Section 70.21 10 CFR 70, and shall advise the Commission in writing when the installation of the radiation monitoring system is complete".

We complied with the request as called for in the above item in February, 1959, but inadvertently did not notify you of our compliance. We regret the delay and request that you accept our notification of compliance at this time.



Very truly yours,

THE MARTIN COMPANY

W. W. Wachtl,

Memorandum

TO : Lyall Johnson, Chief
Licensing Branch

DATE:

FROM : Clifford K. Beck, Chief
Hazards Evaluation Branch

SUBJECT: MARTIN COMPANY - DOCKET 70-58, PROJECT S-16

We have reviewed the Martin Company application dated June 21, 1960 describing shipping procedures for transporting fuel elements to the Universities of California and Washington.

We have commented on the Martin Company shipping container (my memo 6/10/60). Martin describes in the present application a procedure designed to prevent comingling enroute of the Martin shipment with other shipments of SNM. This proposed procedure is limited to a notation typed on the bill of lading which is to be acknowledged by signature of the Railway Express driver.

We do not believe that printing of the request (not to ship other radioactive materials in the same car) on the bill of lading and the driver signature will adequately protect against comingling unless the Railway Express Company will certify that such procedures are adequate for this purpose. Until we have such assurance we cannot recommend approval of this proposed plan.

SUBJECT: THE MARTIN COMPANY REQUESTS DATED JUNE 17, 1960, AND APRIL 18, 1960, AS AUGMENTED JUNE 21, 1960, FOR AMENDMENT TO THE SPECIAL NUCLEAR MATERIAL LICENSE NO. SNM-53 - DOCKET NO. 70-58

SYMBOL: LRL:TGM

ANALYSIS AND FINDINGS

Reference is made to the memorandum to the files dated March 30, 1960, regarding the observations, conclusions and findings resulting from the review of The Martin Company's request for amendment to their Special Nuclear Material License.

By letter dated June 17, 1960, the licensee requests authorization to receive, possess and use .7 milligrams of plutonium fabricated as an alpha source as a calibration standard.

By letter dated April 18, 1960, as augmented June 21, 1960, the licensee requests ~~that~~ authorization to ship uranium-aluminum type fuel elements to the Universities of California and Washington.

From a review of the request of June 17, 1960, it has been determined that the licensee has adequate training and procedures for safely handling the requested source.

Reference is made to the memoranda in the file from HEB dated June 10, and June 28, 1960. A review of the proposed shipping containers and procedures have been determined to adequately meet the requirements of the Act and the regulations of the Commission with the possible exception of the licensee's ability to assure that comingling of material in transit will not occur. It does appear, however, that the licensee proposes to take all practical measures to insure that comingling will not occur.

It is therefore recommended that the licensee's requests be granted and the license be amended to include the requested alpha source and that the cover letter for the amended license grant one time authority for the shipping of the uranium-aluminum fuel elements to the Universities of California and Washington.

Gentlemen:

Pursuant to 10 CFR 71, you are hereby authorized under your License SNM-53 to ship on a one-time-only basis, uranium-aluminum fuel elements to the Universities of California and Washington in accordance with the procedures submitted in your application dated April 18, 1960, as augmented June 21, 1960. This authorization expires when shipment is completed or on December 31, 1960, whichever is earlier.

Enclosed is Special Nuclear Material License No. SNM-53 as amended to authorize the receipt, possession and use of 0.7 milligrams of plutonium fabricated as an alpha source, as requested in your letter of June 17, 1960. For information regarding procurement prior to June 30, 1961, of the allocated alpha source, you should communicate with the Dayton Area Office, U. S. Atomic Energy Commission, P. O. Box 66, Miamisburg, Ohio, Attention: Mr. W. B. Creamer, Area Manager.

ATOMIC ENERGY COMMISSION

SPECIAL NUCLEAR MATERIAL LICENSE

Pursuant to the Atomic Energy Act of 1954 and Title 10, Code of Federal Regulations, Chapter 1, Part 70, "Special Nuclear Material Regulations," a license is hereby issued authorizing the licensee to receive and possess the special nuclear material designated below; to use such special nuclear material for the purpose(s) and at the place(s) designated below; and to transfer such material to persons authorized to receive it in accordance with the regulations in said Part. This license shall be deemed to contain the conditions specified in Section 70.32(a) of said regulations, and is subject to all applicable rules, regulations, and orders of the Atomic Energy Commission now or hereafter in effect and to any conditions specified below.

Licensee	
1. Name The Martin Company	3. License No. [illegible], as amended
2. Address Baltimore 3, Maryland	4. Expiration Date April 30, 1961
	5. Docket No. 70-[illegible]

6. Special Nuclear Material

Uranium enriched in the U-235 isotope, and plutonium

7. Maximum quantity of special nuclear material which licensee may possess at any one time under this license 500 kgs U-235 contained in uranium enriched in the U-235 isotope as UO_2 and metal, 160 grams Pu-239 as an encapsulated Pu-Be neutron source, and .7 milligrams Pu-239 as a Pu-alpha source.

8. Authorized use: In accordance with the procedures described in the licensee's applications dated Oct. 11 and Oct. 2[illegible], 1956; applications executed Dec. 6, 1957, and Jan. 15, 1958; procedures filed Dec. 16, 1958; applications dated March 23 and June 17, 1960.

9. Quantity of special nuclear material allocated to licensee pursuant to Section 70.31(b) of said part

0.7 milligrams of plutonium fabricated as Pu-Alpha source herein allocated.

CONDITIONS

10. Unless otherwise specified, the authorized place of use is the licensee's address stated in Item 2 above.

Notice of Special Meeting of Stockholders

TO THE STOCKHOLDERS:

Notice is hereby given that a Special Meeting of the stockholders of The Martin Company will be held on October 9, 1961 at 11:00 o'clock a.m., Eastern Daylight Saving Time, at the offices of the Company, Middle River, Baltimore County, Maryland, for the following purposes:

(1) To consider and take action upon the proposed Articles and Plan of Consolidation (the Plan) of The Martin Company with American-Marietta Company, an Illinois corporation, declared advisable by the Board of Directors, pursuant to which a new corporation to be designated Martin-Marietta Corporation will be formed under the laws of the State of Maryland. The new corporation when so formed will issue shares of its stock to stockholders of The Martin Company and American-Marietta Company in accordance with the Plan, and will succeed to all of the assets of The Martin Company and American-Marietta Company and assume all of their respective liabilities.

(2) To transact such other business as may properly come before the meeting.

Only stockholders of record at the close of business on August 30, 1961, the record date fixed by the Board of Directors, will be entitled to vote at the Special Meeting.

By Order of the Board of Directors

W. L. LUCAS, *Secretary*

Middle River, Maryland

August 30, 1960

Approval by the holders of a majority of the total number of shares outstanding on August 30, 1961 is required to approve the proposed consolidation. Whether or not you plan to attend the Special Meeting of the stockholders, you are requested to sign and return at once the accompanying Proxy. If you do attend the meeting, you may vote there in person should you so desire.

A/69

PROXY STATEMENT
FOR SPECIAL MEETING OF STOCKHOLDERS
TO BE HELD OCTOBER 9, 1961

There is enclosed herewith a Notice of a Special Meeting of Stockholders of The Martin Company (herein called "Martin") to be held at the offices of the Company, Middle River, Baltimore County, Maryland, at 11 o'clock A.M. Eastern Daylight Saving Time October 9, 1961, and a proxy for the special meeting. The meeting has been called to take action on the proposed consolidation of Martin with American-Marietta Company (herein called "American-Marietta"), an Illinois corporation, into a new corporation to be designated Martin-Marietta Corporation (herein called the "Consolidated Company") which will be formed under the laws of the State of Maryland, the Consolidated Company to succeed to all of the assets of Martin and American-Marietta and assume all of their respective liabilities.

At the Special Meeting Articles and Plan of Consolidation will be submitted to the stockholders for adoption.

REASONS FOR CONSOLIDATION

During the past decade, Martin has experienced rapid growth in the fields of missiles, aerospace and allied electronics and nucleonics activities. The management of Martin is confident that it has the technological capability to remain in the forefront of these activities.

Martin management feels that it now has reached the size and financial position where, for the long term, it should broaden the base of its operations to include major participation in the industrial and commercial growth of the economy. Diversification now and new growth areas for the future are the primary factors which influenced the directors of both companies to approve the proposed consolidation.* American-Marietta's sales in the past decade have grown from $66 million to $368 million and its profits have increased from $2.8 million to $24 million. It is a leading factor in a number of basic growth industries, including paints, industrial finishes, household cleaning products, synthetic resins and adhesives, chemicals as more fully described below, cement, printing inks and a wide variety of building and construction materials. The proposed consolidation offers a unique opportunity to establish a broadly diversified company and there are additional benefits mentioned below that Martin's management believes will result from the consolidation.

Research and New Markets

Both Martin and American-Marietta maintain strong research programs in the development of new materials and products, but to date, Martin because of its lack of commercial outlets, has not been able to translate the application of its technical activities in the commercial market. Its management envisages new opportunities in research and product dvelopment that should result in the application of some of Martin's technical developments for civilian application. There can be no assurance, however, that the consolidation will enable Martin to find commercially profitable outlets for the application of its technical activities. Likewise, American-Marietta's improvements in materials and structural design may fill some of the complex needs of aerospace technology.

Depth of Management

It is believed there is strength and depth of management in both companies—each fully competent in its primary fields of activity and each able to complement the other in achieving the objectives of the Consolidated Company. Under the leadership of Mr. Grover M. Hermann, American-Marietta management has accomplished the growth set forth above.

In the organization and operating structure of the Consolidated Company, it is contemplated that Martin and American-Marietta will each maintain its identity with respect to the management, conduct of its business and customer relations. It is presently contemplated that all of the executive officers of each company will be retained in an executive or administrative capacity and that the various divisions of each of the companies will continue to be operated as separate divisions under the supervision of

* Announcement of these approvals on June 23, 1961 was the first public disclosure of the proposed consolidation.

the persons presently charged with primary responsibility for the conduct of the same. The existing employment agreements between Martin and Messrs. George M. Bunker and Clarence W. Miles (hereinafter on page 22 more fully described) will be assumed by the Consolidated Company which becomes responsible for the compliance with the terms and conditions thereof.

Stronger Corporate Structure

The financial structure of the Consolidated Company, with estimated annual sales based on present operations in excess of $1 billion and total assets of over $500 million, will provide a strong base for such future activities as may be desirable to permit the further growth of the company's business. In addition, the consolidation will generate a cash flow of sizeable proportion, a total of $68 million for the two companies in 1960.

Benefits To Martin Stockholders

Under the terms of the consolidation, Martin stockholders would receive 1.3 shares of common stock of the Consolidated Company for each share presently held, and American-Marietta common stockholders would receive a share-for-share exchange. In arriving at such exchange ratios, consideration was given to the diversity of the businesses of the constituent companies, the earnings of each company for the current and preceding five (5) years, the market values of the shares of each company prevailing during the said period, the book value of each company's common stock and the prospective earnings for each company for 1961 and 1962. Such consideration resulted in the conclusion by the respective managements of the two companies that the aforementioned basis of exchange was an equitable one. (See pages 17-19 hereof with respect to Per Share Earnings, Book Value of Common Stocks and Price Range of Common Stocks). The American-Marietta Class B stock would be eliminated and its holders would receive 4½% Cumulative Preferred Stock (non-convertible) of the Consolidated Company. The book value of such stock at November 30, 1960 was $13.09 per share or an aggregate book value of $42,106,637. It was the best judgment of the respective managements of the two companies, having in mind the dividend limitation (See page 24) and the lack of a market for the Class B Common Shares, as well as the probability that the 4½% Cumulative Preferred Stock to be issued would have a market value less than the par value thereof, that a fair and equitable basis of exchange would be one whereby holders of Class B Common Shares would receive shares of 4½% Cumulative Preferred Stock (non-convertible) of the Consolidated Company representing approximately 90% of the book value of said Class B Common Shares or $38,000,000. This basis of exchange represents approximately 12/100ths of a share of the new preferred stock for each Class B Common Share. American-Marietta will redeem its outstanding 5% Cumulative Preferred Shares prior to the consolidation.

The effect of the consolidation at the outset would be a reduction in Martin's anticipated per-share earnings for 1961 to about the level of last year's per-share earnings which reflected an increase of 70 per cent over the past five years. However, the consolidation would provide Martin stockholders with an immediate 30 per cent increase in cash dividends based on the recent historical dividend record of both of the constituent companies, increased book value and prospects of long-term stability through immediate diversification and possible future expansion into new growth areas. Payment of dividends by the Consolidated Company is, of course, subject to future business conditions, the Company's earnings and financial condition.

It is the considered opinion of Martin's directors and management that the consolidation is in the best interest of all stockholders.

SUMMARY OF THE PLAN

At meetings held on August 3, 1961, the Boards of Directors of Martin and American-Marietta approved and recommended an Agreement of Consolidation dated as of August 1, 1961 (the Agreement), pursuant to which Martin and American-Marietta (the constituent companies) will be consolidated into a new Maryland corporation to be known as Martin-Marietta Corporation. At the same meeting the Martin Board of Directors adopted a resolution approving proposed Articles and Plan of Consolidation of the constituent companies (the Articles), setting forth the terms of such consolidation and declaring that the proposed consolidation is advisable substantially upon the terms and conditions set forth in the Articles. Copies of the Agreement and the Articles are attached hereto and marked

as Appendix 1 and Exhibit A to Appendix 1, respectively. The American-Marietta Board has approved the Agreement and the Articles.

Briefly stated, the Agreement provides that the title to all of the assets of the constituent companies will devolve upon the Consolidated Company, and the Consolidated Company will assume all of the liabilities of the constituent companies. The Consolidated Company will issue new shares of its capital stock to the holders of the common stock of the constituent companies. The presently outstanding 5% Cumulative Preferred Shares of American-Marietta will be redeemed and retired prior to the consolidation.

Capital Stock Outstanding before and after the Consolidation

On July 31, 1961 Martin had outstanding 6,258,829 shares of Common Stock without par value, which will be converted (on a 1.3 for 1 basis) into 8,136,478 shares of Common Stock of the par value of $1 per share of the Consolidated Company. Arrangements will be made for the matching and combination or the purchase and sale of fractional interests in respect of Martin certificates surrendered for exchange within 60 days after the consolidation becomes effective.

On July 31, 1961, American-Marietta had outstanding: (a) 200,599 5% Cumulative Preferred Shares, $100 par value per share. These shares will be redeemed. (b) 3,191,189 Class B Common Shares, $2 par value. It is anticipated that prior to the consummation of the consolidation but after the approval thereof by the stockholders of the constituent companies, 70,314 of these shares will be converted into an equal number of Common Shares and simultaneously therewith 70,314 of the outstanding Common Shares of American-Marietta will be surrendered to it as a capital contribution, with the result that there will be no net increase in the number of American-Marietta Common Shares outstanding. The remaining 3,120,875 Class B Common Shares will be converted into 380,000 shares of 4½% Cumulative Preferred Stock, $100 par value of the Consolidated Company. (c) 13,199,875 Common Shares, $2 par value, which will be converted into a like number of shares of Common Stock, $1 par value of the Consolidated Company.

The preferred stock to be issued by the Consolidated Company will not be convertible into shares of Common Stock. The terms, conditions and provisions of the 4½% Cumulative Preferred Stock are fully set forth in Article IV, subdivision SIXTH, of the Articles hereto attached.

Warrants and Stock Options

Holders of Warrant Certificates issued by Martin pursuant to its Indenture dated as of November 1, 1958, to Fidelity-Baltimore National Bank, as Trustee, will be entitled to subscribe for shares of Common Stock of the Consolidated Company in accordance with the terms of the Indenture.

Each Warrant upon the consolidation becoming effective will entitle the holder to subscribe for 2.73 shares of Common Stock of the Consolidated Company for $40 to and including November 1, 1963, and for $45 thereafter and to and including November 1, 1968. Shares of Common Stock will be reserved by the Consolidated Company for issuance upon the exercise of such Warrants.

Holders of stock options granted by Martin, upon the consolidation becoming effective, will be entitled to purchase from the Company 1.3 shares of Common Stock of the Consolidated Company in the place and stead of each share of Common Stock without par value of Martin which such holder was entitled to purchase immediately prior to the consolidation, subject, however, to such minor adjustment as may be necessary to preserve the "restricted" status of the stock options under the United States Internal Revenue Code. Shares of Common Stock will be reserved by the Consolidated Company for issuance upon the exercise of such stock options.

Effective Date

The consolidation will become effective after approval by the stockholders of the constituent companies at the special meetings to be held on October 9, 1961, and upon compliance with the laws of the States of Maryland and Illinois in relation to the filing of the Articles with the public authorities in those states.

Termination and Abandonment of the Consolidation

The Agreement may be terminated and the consolidation abandoned by resolution of the Board of Directors of either of the constituent companies if certain conditions of that company's obligations set forth in the Agreement are not satisfied. The Agreement may be terminated and the consolidation abandoned by the two constituent companies (each acting by its Board of Directors) by mutual consent, at any time before the consolidation becomes effective. In the event of any termination of the Agreement and abandonment of the consolidation, neither of the constituent companies shall have any liability to the other for costs, expenses, loss of anticipated profits, or otherwise, in connection with the Agreement.

It is not contemplated that the Agreement will be terminated or abandoned for any reason other than the failure on the part of either of the constituent companies to comply with its covenants and obligations thereunder.

BUSINESS AND PROPERTIES OF AMERICAN-MARIETTA

American-Marietta is engaged directly and through subsidiaries in the production, manufacture and sale of construction materials and products, a wide variety of chemicals and chemical products sold to numerous industries, and other miscellaneous products, all as more fully described below. The approximate percentage contribution of these three groups to consolidated net sales for the fiscal year ended November 30, 1960 were as follows: construction materials—44%, chemicals and chemical products—41%, miscellaneous products—15%. The number of persons employed by American-Marietta as of June 30, 1961 was 16,247.

Construction Materials

Cement. Portland cement is widely used in many types of construction. It is sold in bulk to ready-mix concrete producers and to contractors for use in building highways, airports, bridges, dams, waterways, military installations and other structures. Portland cement and mortar cement, used in brick and stone construction, are also sold to independent distributors and dealers.

Cement is produced by the following divisions of American-Marietta: Dragon Cement, with plants in Northampton, Pennsylvania, and Thomaston, Maine; Standard Lime & Cement, with a plant at Martinsburg, West Virginia; Southern Cement, with two plants near Birmingham, Alabama; and Dewey Portland Cement, with plants in Dewey and Tulsa, Oklahoma, and Davenport, Iowa. American- Marietta believes that reserves of limestone and cement rock adjacent to its various plants are sufficient for many years of operations at current levels.

Concrete products. These include machine and precast concrete pipe for sewers, culverts, water mains, irrigation lines and other uses; pre-stressed concrete bridge sections; concrete cribbing; and other structural elements of precast concrete. American-Marietta and its subsidiaries operate a large number of concrete products plants in the United States and Canada. The cement for American-Marietta's concrete products is largely purchased from other suppliers and not from American-Marietta's own plants. The products are generally sold direct to contractors and to states, municipalities and other governmental units.

Aggregates. Aggregates, meaning crushed stone, sand and gravel, are used in building highways, in other types of heavy construction and in making concrete. American-Marietta's principal quarries and crushing plants for producing these products are in North Carolina and Iowa.

Other construction materials and products. These include common and face brick; hollow and drain tiles; aluminum and architectural products and electrical construction products of American-Marietta's subsidiary, Steel City Electric Company, such as electrical outlet and switch boxes, floor boxes, conduit and cable fittings, and pipe and conduit hangers. The Master Builders Company division produces "Pozzolith", an additive to promote dispersion in concrete, which American-Marietta classifies as a chemical product.

Chemicals and Chemical Products

Paint, finishes and coatings. These products include primers, surfacers and finishes for use on automobiles, trucks, buses, farm machinery, railroad cars, prefabricated houses, office equipment, furni-

ture and appliances; heavy duty maintenance paint for industrial use; and chemical coatings made by the Stoner-Mudge division for lining cans and other metal containers for foods and beverages. A large part of the products in this group are produced to customers' specifications and sold directly to manufacturers, not only in the United States and Canada but also to a limited extent in France, Holland and other foreign countries.

Chemical lime, refractories and silica sand. The Standard Lime & Cement and Southern Cement divisions produce chemical lime, which is sold to the chemical and paper industries and to municipalities and industries for water and waste treatment; fluxing lime, crushed stone and magnesite for the steel industry; and clinkered dolomite used in refractories. Other divisions produce silica sand used in the manufacture of glass and for other purposes. As in the case of cement, American-Marietta believes that its reserves of raw materials for these products are adequate for many years of operations.

Printing inks. Many types of printing inks are manufactured by the Sinclair and Valentine division for use in printing and packaging. This division has numerous plants in the United States, a number in Canada, and operations in Mexico, Germany, Switzerland and South America.

Adhesives, resins and chemicals. This group of products includes synthetic resins, glues and adhesives which are sold to the plywood, paper and hardboard industries for bonding purposes.

Dyestuffs. The Southern Dyestuff ("SODYECO") division manufactures ready-to-use sulphur and vat dyes and other coloring materials for the textile industry.

Miscellaneous Products

Other industrial products. American-Marietta and its subsidiaries also manufacture sealants for the aircraft, automotive, construction, electrical communications, foundry, and household appliance industries; metallurgical products such as metal powders, pigments, abrasives and alloys used in the aircraft, missile, and automotive and other industries; machinery and equipment used in heavy construction and metal fabrication; and industrial cleaning products.

Consumer Products. Latex, Alkyd and oil base paints for use by consumers are produced and sold under a variety of trade names, including "American-Marietta", "Arco", "Valdura", "Rev Satin", "Jelled Magic", "Sewall", "O.P.W." and "Berry Bros." Sales are principally to jobbers and retail outlets. The O-Cedar division manufactures mops, polishes, waxes and other household institutional cleaning products.

Federal Trade Commission Proceedings

American-Marietta's business in cement, concrete products and aggregates and in lime and limestone products herein described stems originally from its acquisitions of numerous companies engaged in these businesses, although the acquired properties have been substantially enlarged under American-Marietta's ownership. On January 27, 1961 the Federal Trade Commission issued a complaint under Section 7 of the Clayton Act charging that American-Marietta's acquisitions may lessen competition or tend to create a monopoly in the above lines of commerce in various sections of the country and constitute unfair methods of competition under Section 5 of the Federal Trade Commission Act. To date, no hearings have been held, and American-Marietta has advised Martin that it cannot predict the outcome of the proceedings at this time. If the charges in the complaint were sustained, the remedies available to the Commission might include divestiture of certain of the acquired businesses. Under the provisions of American-Marietta's long term notes, if such a divestiture involved sale of a substantial part of the company's assets, the company would have to offer to apply the proceeds to retirement of an equal amount of its long term debt.

Research

American-Marietta puts substantial emphasis on research. New products and product improvements are sought through a program related closely to customer activities and requirements. To implement this program research activity is decentralized in 25 laboratories run by the operating divisions and subsidiaries. The approximate dollar amount spent on reasearch during the 1960 fiscal year was $4,150,000 not including dues paid trade associations, a substantial portion of which is spent on research in their respective industries.

Plants and Facilities

The plants of American-Marietta and its subsidiaries differ greatly in size and importance, depending upon the nature of the product manufactured. Its management considers them to be well maintained and in satisfactory condition. Most of the manufacturing facilities of American-Marietta are owned by it and, for the most part, are unencumbered. However 32 of the printing ink plants, 16 of the concrete products plants, 26 of the aggregates plants and 1 other plant are operated in leased premises. The locations of the principal plants and facilities are listed below.

BUSINESS AND PROPERTIES OF MARTIN

General

Martin is now primarily engaged in the design, development and production of guided missiles, electronics equipment, communications equipment, aerospace vehicles, and nuclear products.

Martin's military sales and sales to other customers for the past five calendar years and for the first six months of 1961 were as follows:

Year	Military		Other	Total
	Missiles, Electronics and Nuclear	Aircraft		
1956	$126,171,000	$231,869,000	$ 922,000	$358,962,000 *
1957	245,796,000	177,054,000	1,075,000	423,925,000
1958	287,347,000	192,390,000	3,907,000	483,644,000
1959	410,125,000	111,083,000	2,499,000	523,707,000
1960	601,306,000	48,676,000	1,246,000	651,228,000
January } June } 1961...	398,739,000	8,611,000	843,000	408,193,000

* Before adjustment of $2,387,891 as a result of renegotiation for the year 1956.

Martin's backlog of military and other orders at the end of each of the past five calendar years and at June 30, 1961 were as follows:

Year	Military		Other	Total
	Missiles, Electronics and Nuclear	Aircraft		
1956	$ 521,866,000	$289,148,000	$ 379,000	$ 811,393,000
1957	496,978,000	297,900,000	176,000	795,054,000
1958	597,934,000	232,071,000	1,514,000	831,519,000
1959	814,563,000	85,623,000	368,000	900,554,000
1960	1,004,081,000	22,283,000	414,000	1,026,778,000
June 30, 1961....	996,663,000	14,886,000	705,000	1,012,254,000

As the above tables indicate, missiles, associated equipment, electronic systems and nuclear products accounted for approximately 98% of Martin's total backlog of orders at June 30, 1961.

Martin's missile business includes a variety of products and weapons, those capable of massive destruction and usable as aerospace vehicles, and those capable of use in limited warfare. The missiles include those powered with jet engines, those powered with liquid fueled rockets and those powered with solid fueled rockets.

Mace

The Mace is an outgrowth of the Matador, one of the earliest missiles produced by Martin. The Mace is a highly mobile surface-to-surface tactical missile designed in two types (the Mace A and the Mace B) both of which have self-contained guidance systems. Associated with the Mace is a substantial volume of ground support equipment produced by Martin.

Bullpup

The Bullpup is a short-range, air-to-surface missile first developed and produced by Martin under contracts with the Navy. Versions of the missile are produced for use by the Air Force as well as the Navy, and it is now in operational use with the Navy, Marine Corps and Air Force. The function of the missile is to provide light attack aircraft with greater capability than was formerly available against tactical targets.

Lacrosse

The Lacrosse is a mobile and highly accurate surface-to-surface guided missile developed as a close support weapon for combat troops. The missile and its associated ground equipment have been

in production since 1957. The missile is propelled by a solid fuel rocket motor and is capable of delivering both nuclear and conventional warheads.

Titan

The Titan Intercontinental Ballistic Missile is a two-stage liquid fueled rocket powered missile designed to deliver a thermonuclear warhead to a predetermined point more than 6,000 miles from the launching site. Martin is responsible for the airframe, controls and associated ground support and launching equipment, as well as for the functioning of the system as a whole. Martin holds contracts with the Air Force for two types of the Titan missile. The first type, Titan I, is in production and is undergoing advanced flight tests. The Titan II will be larger than Titan I and will be able to carry a heavier payload over even greater distances than the Titan I. It is designed to utilize storable fuels which will make it possible to maintain the missile in a ready-firing condition for long periods of time at ordinary temperatures. It is also being designed for firing from underground sites.

Pershing

Pershing is the United States Army's selective range, surface-to-surface ballistic missile system having a "built-in" jam-proof guidance system. It consists of two stages employing solid propellants and is lighter, smaller, and more mobile than the Army's Redstone system which it is scheduled to replace. As systems contractor, Martin is responsible for research and development, reliability, testing and production of the missile and associated ground equipment.

Dyna-Soar

Dyna-Soar is an advanced boost-glide space vehicle. The Air Force has retained responsibility for the integration of the complete system. Martin has been selected to build the booster portion of the program and holds a contract for the Dyna-Soar launch rocket. The Titan II design will be modified to meet the requirements of the Dyna-Soar Program.

Electronics

Martin's capability in the field of electronics is founded on intensive research and development work begun during World War II and many years of experience in the design, testing, packaging, manufacture and field support of a wide diversity of electronic systems and components.

Martin's electronics activity is staffed by over three thousand five hundred engineers, supported by a full complement of technicians, apart from manufacturing and field service personnel. The engineers average five years of electronics experience with Martin. Electronic engineers in supervisory capacities average more than ten years of experience with Martin.

Major electronics programs have been conducted at Baltimore since 1946, at the Denver Division since its founding in 1956 and at the Orlando and Cocoa Divisions since 1957. A complete electronics staff and facility has been established in Baltimore.

One of Martin's major programs is the electronic system known as Missile Master, developed, produced and serviced under contract with the Army. The function of the system is the integration of anti-aircraft missile batteries for the air defense of the nation's principal industrial and population centers. Martin has completed delivery of the systems originally ordered, and now has an order for additional systems known as "BIRDIE", more compact but similar to the Missile Master.

Nuclear Activities

Martin's nuclear activities are centered at Baltimore where the Nuclear Division was formed in 1954 to provide emphasis on and control over those activities. Today the Division is organized in five product departments. During 1961 the Nuclear Powerplant Department is scheduled to complete two "packaged powerplants" under contract with the Atomic Energy Commission. The first of those, designated PM-1, will be installed at an Air Force radar station near Sundance, Wyoming. The other, known as PM-3A, will be shipped to McMurdo Sound, Antarctica. The advanced Reactor Systems Department is engaged under contract in research and development for a liquid fluidized bed reactor, the goal of which is to provide basically simpler operating techniques and significantly lower fuel costs than those involved in existing systems. The propulsion Systems Department is at work on several classified government projects, including its contribution to a study contract for the National Aeronautics and Space Agency in the RIFT (Reactor in Flight Test) program, under which plans are

being formulated for the flight testing of the first nuclear rocket engine. The Auxiliary Power Systems Department is producing a variety of direct conversion generators which require no moving parts. SNAP-3, the first such generator to use the decay heat of radioisotopes as a basic energy source, was delivered to the AEC early in 1959. As a result of the pioneer efforts in the development of SNAP-3, the Company has since developed similar generators that have been used in the first nuclear powered satellite (the Transit) and in the world's first radioisotope fueled weather station.

Research and Development

Martin's business depends greatly upon technological progress and great emphasis is placed upon research, engineering, development and testing. Therefore Martin has spent and expects to continue spending substantial sums of money in these areas. In addition to the programs described above, Martin has other research and development programs, some of which are in the very early research stage preparing Martin for future competitions for military products, while other programs have reached the stage of development, including the design and building of prototype military equipment. Among the outgrowths of these research and development efforts are two study contracts received within the past year: Project Apollo, designed to provide the capability for manned reconnaissance flights to the vicinity of the moon; and a contract for a study of SLOMAR, seeking the solution to the problems of providing freight, passenger, maintenance and rescue service for orbiting satellites and space stations.

As a part of its activities in the field of research, Martin's RIAS division is staffed with a selected group of scientists who create and conduct their own programs of research, including both theoretical and experimental studies.

Government Contracts

Substantially all of Martin's contracts with the Government are either the cost reimbursement type (cost-plus-a-fixed-fee) or the fixed priced incentive type.

The cost reimbursement type contract provides for reimbursement of costs (with certain exceptions) incurred in connection with the performance of the contract and a fixed fee specified in each contract. The fixed price incentive type contract provides for participation by Martin and the Government in either savings or excess costs with relation to an established target price.

Under fixed price incentive type contracts, Martin receives progress payments, generally in an amount equal to 70% of costs incurred. Martin's definitive cost reimbursement type contracts now provide for current reimbursement by the Government of 100% of costs incurred, and during the period of negotiation letter contracts provide for reimbursement of 70% of costs incurred.

The Renegotiation Act of 1951 as amended makes subject to renegotiation by the Government substantially all of Martin's profits through June 30, 1962, the present expiration date of the Act. Clearances under the Renegotiation Act have been received through the year 1952 with no refunds being required. Reference is made to Note A to Martin's earnings under "Summaries of Earnings" regarding required refunds and other information with respect to years subsequent to 1952 and for the year 1957.

Property

The Company's principal manufacturing plants are located near Baltimore, Maryland; Denver, Colorado and Orlando, Florida. Corporate offices, the Baltimore Division, and the Nuclear Division are located at Middle River, Maryland, approximately 12 miles east of the center of Baltimore. The facilities there provided comprise approximately 3,240,000 square feet owned by the Company and 157,000 square feet owned by the Government and operated by the Company under a Use Agreement. Property owned by the Government is made available to the Company without payment of rental unless the facilities are used for other than Government purposes. The land at Middle River owned by the Company aggregates approximately 1,000 acres and includes a modern military airport. In addition to the property at Middle River, the Company leases in the Baltimore area approximately 284,000 square feet of space for office and storage purpose. A new Corporate Administrative Headquarters is presently being constructed at Baltimore Friendship International Airport. The building will contain approximately 80,000 square feet.

The Company in 1955 acquired by purchase approximately 3,860 acres of land near Denver, Colorado, which has been improved by the construction of administration, engineering and manufacturing

buildings containing in the aggregate approximately 1,396,000 square feet. The Company leases approximately 2,500 acres of land adjacent to the Denver plant site and also for its activities in the Denver area, office and storage space containing approximately 540,000 square feet. Some 140,000 square feet of government-owned space is used by the Company in the Denver area.

The Company acquired in 1956 by purchase approximately 6,770 acres of land near Orlando, Florida for use of the Orlando Division in the production of guided missiles and electronics. A fully integrated plant containing approximately 760,000 square feet has been completed at this location. In addition to the property owned by the Company, the Orlando Division utilizes for office and storage purposes leased areas containing approximately 371,000 square feet.

Leased offices are maintained at Cocoa Beach, Florida for the Cocoa Division, and at Boston, Massachusetts; Chicago, Illinois; Cleveland and Dayton, Ohio; Los Angeles, California; New York City; Honolulu, Hawaii; Washington, D. C.; Hampton, Virginia; Huntsville, Alabama; Red Bank, New Jersey; Omaha, Nebraska; Rome, New York, and Wiesbaden, Germany, for representatives of the Company in those areas. The Company also leases facilities at Quehanna, Pennsylvania, for the use of its Nuclear Division.

During the five years ended December 31, 1960 the Company and its subsidiaries made gross property additions of $76,492,905 and property retirements aggregating $6,037,814.

Substantially all of the above buildings are of modern fireproof construction and have been maintained in good operating condition.

The Company knows of no material defects in title to any material portions of the properties owned by it nor of any material encumbrances thereon. No special examinations of title to properties have been made in connection with this offering.

CAPITALIZATION

The capitalization of the Constituent Companies (Martin as of June 30, 1961, American-Marietta as of May 31, 1961) and pro-forma of the Consolidated Company based on the combination of the foregoing is as follows:

	(In Thousands)		
	Martin	American-Marietta	Consolidated Company
Long Term Debt (exclusive of amounts payable within one year)			
Unsecured notes held by financial institutions		$ 67,930(1)	$ 67,930
5½% Sinking Fund Debentures due November 1, 1968 held by the public	$ 15,500(2)		15,500
Other		956	956
Preferred Stock			
5% Cumulative, $100 par value, 200,599 shares outstanding		20,060(3)	
4½% Cumulative, $100 par value, 380,000 shares outstanding			38,000(4)
Stockholders' Equity			
Common Stock, No Par value, 6,258,387 shares outstanding	3,129(5)		
Common Stock, $2 par value, 13,200,796 shares outstanding		26,402(6)	
Class "B" Common Stock, $2 par value, 3,191,189 shares outstanding		6,382(7)	
Common Stock, $1 par value, 21,336,699 shares outstanding			21,337
Additional paid-in capital	40,367	88,926	105,869
Earnings reinvested	58,322(8)	94,474(9)	151,793
	$117,318	$305,130	$401,385

NOTES:

(1) Consists of long term debt of American-Marietta, which will be assumed by the Consolidated Company. The interest rates, maturities and payments required in the next five years are shown in the Notes to American-Marietta's balance sheet in this Proxy Statement.

(2) Consists of long term debt of Martin, which will be assumed by the Consolidated Company. The sinking fund requirements are shown in the Notes to Martin's balance sheet in this proxy statement.

(3) To be redeemed prior to consolidation.

(4) The terms of the 4½% Cumulative Preferred Stock provide for an annual sinking fund of $1,150,000 and limit dividends and other payments in respect of the Common Stock to net income subsequent to November 30, 1961 plus $45,000,000.

(5) Each share to be exchanged for 1.3 shares of Common Stock, $1 par value, of the Consolidated Company.

(6) Each share to be exchanged for 1 share of Common Stock, $1 par value, of the Consolidated Company

(7) To be exchanged for 380,000 shares 4½% Cumulative Preferred Stock, $100 par value.

(8) Under the terms of the Debenture Agreement covering the 5½% Sinking Fund Debentures, $13,707,517 of the earnings reinvested are not available for the payment of dividends.

(9) Under the terms of notes payable to financial institutions, payments which may be made for the payment of dividends (other than on preferred shares) and for the acquisition of capital shares were limited to $14,000,000.

(10) The Consolidated Company, by operation of law, will assume the obligations of Martin in respect of the warrants and options described in the Notes to Martin's balance sheet herein. The number of shares of the Consolidated Company's Common Stock covered by the warrants will be 1.3 times the number of Martin's shares now covered. The number covered by the options will be approximately 1.3 times the number now covered, with such adjustment as may be necessary to preserve the "restricted" status for purposes of the Internal Revenue Code. All figures are based on shares outstanding June 30, 1961 as to Martin and May 31, 1961 as to American-Marietta, and would be changed by exercise of options, warrants and conversion rights after those dates.

PRO FORMA COMBINED SUMMARY BALANCE SHEET

(Giving effect to the proposed consolidation of The Martin Company and American-Marietta Company)

The pro forma combined summary balance sheet, giving effect to the proposed consolidation of The Martin Company and American-Marietta Company on a "pooling of interests" basis, combines the balance sheet of Martin and the consolidated balance sheet of American-Marietta and consolidated subsidiaries as of the end of the first six months of each of their respective 1961 fiscal years. The pro forma balance sheet should be read in conjunction with the aforementioned separate balance sheets of Martin and American-Marietta and the related notes to the respective financial statements appearing elsewhere in this proxy statement.

	$212,105	$369,263		$581,368

The pro forma adjustments give effect to the following:

1. Retirement of 5% Cumulative Preferred Shares at $105 per share prior to the consolidation, either from cash on hand and/or proceeds of short term bank loans. The retirement premium of $1,003,000 has been charged to earnings reinvested.

2. Conversion of all of the outstanding American-Marietta Class B Common Shares, $2 par value, for 380,000 new 4½% Cumulative Preferred Stock, $100 par value (aggregate par value $38,000,000), of the Consolidated Company.

3. Conversion (on the basis of 1.3 shares for 1 share) of all of the 6,258,387 outstanding shares of Martin Common Stock, without par value (aggregate stated value $3,129,193), for 8,135,903 common shares, $1 par value of the Consolidated Company, and conversion (on a 1 for 1 basis) of all of the 13,200,796 outstanding American-Marietta Common Shares, $2 par value (aggregate par value $26,401,592), for 13,200,796 shares of Common Stock, $1 par value of the Consolidated Company. The aggregate par value, $21,336,699, of all of the 21,336,699 shares of Common Stock of the Consolidated Company to be outstanding will be $8,194,086 less than the combined aggregate of the stated value of Martin Common Stock and the par value of American-Marietta Common Shares outstanding.

4. Reduction of additional paid-in capital by $23,423,536, representing the amount by which the combined aggregate par value of the new 4½% Cumulative Preferred Stock and Common Stock of the Consolidated Company exceeds the combined aggregate par value of Martin Common Stock and American-Marietta Common and Class B Common Shares outstanding.

STATEMENTS OF EARNINGS

The Martin Company

The following statement of earnings of the Company for the five years ended December 31, 1960 has been reviewed by Touche, Ross, Bailey & Smart, independent certified public accountants, whose opinion appears elsewhere in this Proxy Statement; the information for the six-month periods ended June 30, 1960, and June 30, 1961, has not been audited. The statement of earnings should be read in conjunction with the financial statements and related notes included elsewhere in this Proxy Statement. The unaudited figures for the six months ended June 30, 1960 and June 30, 1961 include all known adjustments (consisting only of normal recurring accruals) considered necessary for a fair presentation of earnings for the respective periods.

During the period from January 1, 1956 through October 31, 1958 the Company had certain subsidiaries, the operations of which are included in the statement of earnings for the years ended December 31, 1956, 1957 and 1958. All of these subsidiaries were merged into the Company October 31, 1958.

The accompanying earnings statement for the year 1956 has been restated to give effect to the renegotiation refund described in Note A and the effect of such refund upon the federal taxes applicable to that year.

NOTES

(A) Under the Renegotiation Act of 1951, the Company has received clearance from The Renegotiation Board for 1952 and prior years and for the year 1957. The Renegotiation Board has made unilateral determinations that the Company's profits were excessive for the years 1953 to 1956. The effect of the Board's actions is summarized below:

	Excessive Profits Determined By Board	Requested Refund, Net of Federal And State Tax Credits	Liability In Accounts As Of Dec. 31, 1960 and June 30, 1961
1953	$3,500,000	$1,526,192	$ (1)
1954	6,250,000	2,816,793	2,816,793
1955	3,500,000	1,430,279	1,430,279
1956	4,796,101	2,008,316	1,146,188 (2)
			$5,393,260

(1) Year 1953 paid under protest—Company has a claim for Federal income tax refundable in the amount of $1,636,567.

(2) Amount provided for 1956 is net of a claim which was before the Armed Services Board of Contract Appeals to recover certain contract costs previously disallowed. The claim has been denied and the requested refund should be correspondingly reduced by The Renegotiation Board.

The Company believes that no excessive profits were realized for the years 1953 to 1956 and has appealed to the Tax Court for a redetermination of the Board's findings for these years. The Renegotiation Act provides that on appeal, if the Tax Court shall find excessive profits were realized, it has the power to determine that the amount of such excessive profits is less than, equal to or greater than that determined by the Board.

The earnings statement for 1956 has been restated to reflect the Board's determination in the accounts, and the federal income taxes for 1956 have been reduced by $1,241,703 to reflect the refundable federal taxes applicable to such renegotiation refund.

Sales and profits for 1958 and subsequent years are also subject to renegotiation. The Company has no basis for anticipating the final actions of The Renegotiation Board and intends to take such actions as may be required to sustain its position that no excessive profits have been realized for any year. Accordingly, no provisions have been made in the accounts for 1958 or subsequent years.

(B) The Company incurred production costs of approximately $92,000,000 to December 31, 1958 (of which $40,000,000 was incurred in the prior year) under a letter contract, originally contemplating a definitive fixed price contract. In subsequent negotiations the Company and the Government agreed that the definitive contract would be of a cost reimbursement type. Accordingly, pursuant to its regular accounting policy in accounting for contracts of this type, during 1958 sales were recorded in the amount of approximately $98,000,000 on which the net income was approximately $3,165,000 of which approximately $1,375,000 relates to costs incurred in the prior year.

(C) The caption Selling, General and Administrative Expenses has been omitted as being inapplicable since substantially all of the Company's costs and expenses are incurred in connection with production under sales contracts and accordingly have been consistently considered to be directly applicable to performance under such contracts and are, therefore, classified in the financial statements as work in process or cost of sales.

(D) Cost of sales includes provisions for Maryland and Colorado State income taxes as follows: years ended December 31, 1956, $718,500; 1957, $605,883; 1958, $717,970; 1959, $523,649; 1960, $744,906, and for the six months ended June 30, 1961, $694,900.

American-Marietta Company and Consolidated Subsidiaries

The following statements of consolidated income of American-Marietta and consolidated subsidiaries for the five (5) years and six (6) months ended May 31, 1961 include the results of operations from dates of acquisitions of companies acquired, except as to companies merged during the years 1956 to 1960 which were treated for accounting purposes as "poolings of interests", the results of operations of which have been included for all periods. In annual reports of American-Marietta to its shareholders for the years 1956 through 1959, the results of operations of these companies have been included only from the beginning of the fiscal year in which the acquisition took place; and to this extent results of operations shown herein differ from those reported in such years.

The statements reflect certain retroactive adjustments relating to earnings of foreign (except Canadian) subsidiaries and to federal income taxes and interest thereon as described in Notes A and B of Notes to Financial Statements on page 41.

The statements have been examined for the five years ended November 30, 1960, by Ernst & Ernst and other independent accountants, whose reports with respect thereto are included elsewhere in this Proxy Statement. The statements for the periods of six months ended May 31, 1960, and May 31, 1961, respectively, are unaudited, but American-Marietta Company believes that they reflect all adjustments (consisting only of normal recurring accruals) necessary to present a fair statement of the results of operations for these periods. The statements should be read in conjunction with the related consolidated financial statements of American-Marietta Company and consolidated subsidiaries and notes thereto included elsewhere in this Proxy Statement.

NOTES:

(1) Alphabetical notes refer to notes to financial statements of American-Marietta Company and consolidated subsidiaries included elsewhere in this proxy statement.

(2) Amounts deducted for dividends on Preferred Shares include an adjustment for Preferred Shares issued in connection with the acquisition of one company which for accounting purposes was treated as a "pooling of interests."

(3) For information as to dividend restrictions on Class B Common Shares and the basis upon which Class B Common Shares may be converted into Common Shares, reference is made to Note D of notes to financial statements.

(4) The annual dividend requirement on Preferred Shares outstanding at November 30, 1960, was $994,860 and at May 31, 1961, $1,002,995.

(5) Net sales and net income for the six months ended May 31, 1961, are not necessarily indicative of the results of operations which may be expected for the entire year ending November 30, 1961.

The decline in net income for the six months ended May 31, 1961, as compared to the six months ended May 31, 1960, is attributable to the deferment of building and road construction activities due to unfavorable weather in the early part of the period and to a decline in the volume of business in certain products. This decline, however, has not continued into the current quarter, and sales and net income in the months of June and July 1961, have been greater than in the corresponding months of 1960.

PRO FORMA COMBINED SUMMARY OF EARNINGS

The following pro forma combined summary of earnings has been prepared by combining amounts shown in separate statements of earnings of Martin and of American-Marietta and consolidated subsidiaries (without regard for differing fiscal periods and before deduction of dividends on preferred shares of American-Marietta) after giving effect in all periods to a 5% interest charge (net of income taxes) which would have been incurred had amounts of debt existed equal to the aggregate par value of the American-Marietta 5% Cumulative Preferred Shares then outstanding. The pro forma combined summary of earnings should be read in conjunction with the separate statements of earnings of Martin and of American-Marietta and consolidated subsidiaries and notes thereto included elsewhere in this Proxy Statement.

	(In Thousands)						
						First Six Months	
	1956	1957	1958	1959	1960	1960	1961
Sales	$603,517	$683,873	$761,930	$863,880	$1,019,335	$462,901	$565,423
Net earnings	31,341	29,270	32,485	39,181	40,802	16,368	19,609(1)
Dividend requirements on proposed 4½% Cumulative Preferred Stock of Consolidated Company	1,710	1,710	1,710	1,710	1,710	855	855
Net earnings applicable to common shares	29,631	27,560	30,775	37,471	39,092	15,513	18,754

(1) Includes extraordinary profit of $3,750,000 from sale of investment.

PER SHARE EARNINGS

The following tabulation, based on the Pro Forma Combined Summary of Earnings set forth above, compares, for the periods indicated, the net earnings per share of Common Stock of Martin and of Common and Class B Common Shares of American-Marietta and pro forma combined. The per share earnings for American-Marietta are based on the average shares outstanding during each period, after adjustment for stock splits of 5 for 4 in 1956, 3 for 2 in 1957 and 5 for 4 in 1959; shares issued in acquisition of companies treated for accounting purposes as "poolings of interests" have been considered outstanding from the beginning of the fiscal years of such companies in 1956. The per share earnings for Martin are based on the number of shares outstanding at the end of the respective periods (changes during the periods are not considered to be material), after adjustment for stock dividends of 5% in 1956 and 1959, and stock split of 2 for 1 in 1961. The per share earnings, pro forma, repre-

sent the earnings for each period which would have been allocable to each share of Martin and American-Marietta respectively had the consolidation become effective at the beginning of the fiscal year 1956.

	The Martin Company		American-Marietta Company	
	Before Consolidation	Pro Forma (Based on 1.3 for 1 Conversion)	Before Consolidation Applicable to Common and Class B Common	Pro Forma (Based on 1 for 1 Conversion of Common)

1960	1.24	.98	.54	.75
1961	1.56(1)	.92(1)(2)	.36(2)	.71(1)(2)

(1) Exclusive of extraordinary profit of $3,750,000 from sale of investment equivalent to $.60 per share of Martin before consolidation, and $.23 per share of Martin and $.18 per share of American-Marietta on the pro forma basis.

(2) Per share earnings for the six months ended May 31, 1961, are not necessarily indicative of the results of operations which may be expected for the entire year ending November 30, 1961. The decline in per share earnings for the six months ended May 31, 1961, as compared to the six months ended May 31, 1960, is attributable to the deferment of building and road construction activities due to unfavorable weather conditions prevailing in the early part of the period and to a decline in the volume of business in certain products.

BOOK VALUE OF COMMON STOCKS

There is set forth below a comparison of book values per share of Common Stock of Martin at June 30, 1961 with Common Shares (including Class B) of American-Marietta as of May 31, 1961 and pro-forma for the Consolidated Company.

	Martin June 30, 1961	American-Marietta May 31, 1961	Consolidated Company (Pro-forma)
Common stock equity	$101,817,926	$216,184,171	$278,999,097
Shares of Common Stock outstanding at end of period	6,258,387	16,391,985	21,336,699
Book value per share of Common stock	$16.27	$13.19	$13.08
Book value per share of Martin common stock based on exchange ratio of 1.3 to 1			$17.00

PRICE RANGE OF COMMON STOCKS

The Common Stock of Martin is listed on the New York, Philadelphia-Baltimore and Pacific Coast Stock Exchanges and it is anticipated that the Common Stock of the Consolidated Company will be similarly listed. The Common Shares of American-Marietta are traded in the Over-the-Counter Markets in New York and Chicago and other financial centers. The high and low sale prices of the Common Stock of Martin on the New York Stock Exchange by quarterly periods during the two years 1959 and 1960, and the six months ended June 30, 1961, and on June 30, 1961, are shown below. Market quotations on the Martin Common Stock are reported on the basis of the published closing sale prices on the New York Stock Exchange; whereas quotations on the American-Marietta Common Shares for the

same periods are reported on the basis of bid and asked prices as reported by the National Quotation Bureau, Incorporated of New York City, as follows:

	Martin (1)		American-Marietta (2)			
			Bid		Asked	
Quarter ended	Low	High	Low	High	Low	High
March 31, 1959	$16.19	$22.69	$32.00	$44.00	$32.20	$44.20
June 30, 1959	21.31	31.38	41.20	46.40	41.60	46.80
September 30, 1959	17.69	26.75	37.25	44.00	37.50	44.50
December 31, 1959	19.00	25.38	37.63	42.00	37.75	42.25
March 31, 1960	18.63	22.13	34.00	38.38	34.13	38.50
June 30, 1960	18.00	24.43	31.75	36.50	32.00	36.75
September 30, 1960	22.56	29.31	28.75	34.38	29.00	34.50
December 31, 1960	24.13	32.69	27.63	34.13	27.88	34.25
March 31, 1961	29.31	37.88	30.88	40.50	31.00	40.75
June 30, 1961	30.50	39.00	29.00	37.00	29.75	37.13
On August 15, 1961	35.63	36.50	30.13	30.38	30.50	31.00

(1) Adjusted to reflect the two-for-one split effected on February 10, 1961, for stockholders of record January 20, 1961.

(2) Adjusted to reflect five-for-four split in July, 1959.

The Class B Common Shares of American-Marietta are not listed on any exchange, and there has been no trading in such shares.

DIVIDENDS

The constituent companies since December 21, 1960 as to Martin and February 1, 1960 as to American-Marietta have paid quarterly cash dividends on their respective Common Stocks at the annual rate of $1 per share. Subject to future business conditions and the financial condition of the Consolidated Company which may change from time to time, the managements contemplate the continuance of quarterly dividends on the Common Stock of the Consolidated Company at the same rate.

A summary of cash dividends paid per share, adjusted for stock dividends and splits, is presented below:

	The Martin Company	American-Marietta Company
1956	$ .73	$ .58
1957	.76	.68
1958	.76	.80
1959	.76	.85
1960	.85	1.00
First six months:		
1960	.40	.50
1961	.50	.50

MANAGEMENT

Directors

When the consolidation becomes effective, the Board of Directors of the Consolidated Company will consist of eighteen members, nine of whom are present Directors of Martin and nine of whom have been designated by the Board of Directors of American-Marietta.

The following information is presented in respect of the Martin Directors who will become Directors of the Consolidated Company* and will serve as such until the annual meeting in April, 1962:

Name	Principal occupation for last five years	Martin Director Since	Shares of Martin Common Stock beneficially owned August 4, 1961
George M. Bunker	Chairman of the Board and Chief Executive Officer of The Martin Company	1952	186,490
William B. Bergen	Executive Officer of The Martin Company	1958	23,418
William A. Burns	President and Director, Trailmobile, Inc. (Manufacturers truck-trailers)	1957	420
Clarence W. Miles	General Counsel of The Martin Company and Partner of Miles & Stockbridge (Attorneys)	1958	20,265
John E. Parker	Independent Business Consultant	1956	4,000
Everett H. Pixley	Vice President, Mellon National Bank and Trust Company (Banking)	1949	256
Alexander B. Royce	Partner of Chadbourne, Park, Whiteside & Wolff (Attorneys)	1953	508
Duncan M. Spencer	Chairman of the Board and Executive Officer, Fiduciary Trust Company of New York (Banking)	1952	1,000
John L. Sullivan	Partner of Sullivan, Shea & Kenney and of Sullivan & Wynot (Attorneys)	1952	20,004

*Mr. Frank F. Russell, a director of Martin for many years, was unable to accept a place on the Board of Directors of the Consolidated Company due to the fact that he is a director of another corporation whose business is competitive in certain respects with that of the Consolidated Company.

The following information is presented in respect of the American-Marietta Directors and officers who will become Directors of the new company and will serve as such until the annual meeting in April, 1962:

Name	Principal occupation for last five years	American-Marietta Director Since	American-Marietta Shares beneficially owned July 20, 1961 (1)	
			Common	Class B
Grover M. Hermann	Chairman of the Board of American-Marietta Company	1930	11,671	2,445,650
Robert E. Pflaumer	President of American-Marietta	1954	15,826	70,314
Harry N. Huntzicker	Executive Vice President of American-Marietta, previously Vice President of United States Gypsum Company	1961	600	
William J. Cabaniss	President of Southern Cement Company, now a division of American-Marietta	1956	30,000	
John F. Donoho	Financial Vice President of American-Marietta	——	1,365	
Leigh R. Gignilliat, Jr.	Vice President of American National Bank & Trust Company of Chicago	1953	1,272	
J. Clifford Knochel	Vice President of American-Marietta, previously Vice President of Devoe & Reynolds, Inc.	1959	1,701	
Ray L. Oughton	Director and Vice Chairman of the Board of American-Marietta until his voluntary resignation April 18, 1961, and since then Divisional President of the Madison Silo Division of American-Marietta.	1934	5,372	
W. Trent Ragland	President of Superior Stone Company, now a division of American-Marietta	1960	87,535	

(1) Except as otherwise indicated, includes shares owned by trusts in which the person named has an interest, but does not include shares owned by members of the family of the person named in which such person has no interest.

(2) Does not include Common Shares and Class B Common Shares owned by trusts for members of Mr. Hermann's family in which Mr. Hermann has no beneficial interest and by a charitable foundation which was created by him.

(3) Before the consolidation becomes effective, Mr. Pflaumer expects to convert his Class B Common Shares into Common Shares. After the consolidation becomes effective, Mr. Pflaumer will have an option to purchase 19,125 shares of Common Stock of the Consolidated Company from certain other stockholders.

Holders of Class B Common Shares of American-Marietta as of July 20, 1961

Beneficial owner	Number of Shares
American National Bank and Trust Company, et al. Trustees for benefit of Shirley Hermann	311,275
American National Bank and Trust Company, et al. Trustees for benefit of Robert Hermann	340,061
Grover M. Hermann	2,445,650
Grover M. Hermann Foundation	11,720
Robert Hermann	12,169
Robert Pflaumer	70,314
Total	3,191,189

Election of Officers of Consolidated Company

It is presently intended that the directors named above will meet promptly after the consolidation becomes effective and will elect the following executive officers:

George M. Bunker, President and Chief Executive Officer
Grover M. Hermann, Chairman of the Board
William B. Bergen, Vice-President
Robert E. Pflaumer, Vice-President
John F. Donoho, Financial Vice-President and Treasurer
William L. Lucas, Secretary

At the same time it is intended that Clarence W. Miles will be designated as General Counsel of the Consolidated Company.

Remuneration of Directors and Officers

The following table shows certain information with respect to remuneration paid by Martin to its officers and Directors during the year 1960:

Name of individual or identity of group and capacity in which remuneration was received	Aggregate remuneration	Premium paid by Martin under Employees' Pension Fund Plan (1)
George M. Bunker, Chairman of the Board	$150,000(2)	$16,009
William B. Bergen, President and Director	100,000	9,209
Clarence W. Miles, General Counsel and Director	80,000(3)	None
George T. Willey, Vice President	57,000	9,872
All officers and directors as a group (including above) ..	848,001(4)	68,901

(1) The annual benefit estimated to be payable under the Employees' Pension Plan upon retirement at normal retirement age for George M. Bunker and William B. Bergen is $25,000 and for George T. Willey is $13,377. Clarence W. Miles is not eligible under the Plan.

(2) As of April 1, 1959, the Company entered into a five-year contract with George M. Bunker. Under the terms of the contract Mr. Bunker will devote substantially his entire business time as chief executive and general manager of the Company at an annual salary of $120,000 subject to such increases and additional payments as may be determined by the Board of Directors. If he should be permanently disabled or die during the term of the contract the compensation provided thereby shall be continued for a period of six months.

(3) On October 1, 1960 the Company entered into an employment agreement with Clarence W. Miles by which Mr. Miles agreed to serve as General Counsel for a term of 10 years at an annual salary of not less than $80,000. Either party has the right to terminate the agreement after the expiration of 5 years in which event it is agreed that Mr. Miles shall serve in a consulting capacity at an annual salary of $30,000. In the event that Mr. Miles shall be permanently disabled the Company may terminate the agreement and thereupon the Company shall be obligated to pay the compensation as General Counsel to Mr. Miles for a period of 6 months or in the event of his death during the 6 months period to his widow or his estate.

(4) Does not include $40,900 paid for legal services to Sullivan, Shea & Kenney, of which firm John L. Sullivan, a Director, is a partner; or $32,142 paid for legal services to Miles & Stockbridge, of which firm Clarence W. Miles is a partner.

The following table shows certain information with respect to remuneration paid by American-Marietta to certain of its officers and Directors who will become Directors of the Consolidated Company, during the fiscal year ended November 30, 1960:

Name	Title	Salaries and Fees	Bonuses	Pension, Profit Sharing and Retirement Benefits: Accrued for Year 1960	Pension, Profit Sharing and Retirement Benefits: Estimated Annual Benefits
Grover M. Hermann	Chairman of Board of Directors	$ 98,333	$ —	—	$ 6,000(1)(2)
Robert E. Pflaumer	President and Director	80,000	40,000	$ 3,917	22,064(1)
William J. Cabaniss	Divisional General Manager and Director	36,000	—	1,718	5,220(1)
John F. Donoho	Financial Vice President	40,000	10,000	—	—
J. Clifford Knochel	Vice President and Director	45,000	5,000	2,168	7,000(1)
All Directors and Officers	Directors and Officers	1,108,503	333,210		

(1) Including benefits from contributions by participants under Company's Salaried Employees' Retirement Plan.
(2) Maximum vested benefits under Company's Salaried Employees' Retirement Plan.

Stock Options of Martin

During the period from January 1, 1960 to August 4, 1961, (i) Mr. Bunker exercised options to purchase 42,000 shares (representing all of his then remaining unexercised options) at $15.89 per share, the closing market value on the date of exercise being $36.63; (ii) Mr. Bergen exercised options to purchase 9,260 shares at $12.15 per share, the market value on the date of exercise being $26.88; (iii) Mr. Miles exercised options to purchase 12,600 shares at $15.89 per share and 7,665 shares (representing all of his then remaining unexercised options), at $19.52 per share, the market value per share on the dates of exercise ranging from $27.88 to $36.63; and (iv) Mr. Willey exercised options to purchase 2,100 shares at $15.89 per share, the market value on the date of exercise being $32.31 per share.

During the same period all officers and directors of Martin as a group, including those previously set forth in detail, exercised options as follows:

Quarter or Period Ended	Shares	Option Price	Market Price on Date Purchased
Sept. 30, 1960	19,032	$12.15—15.89	$26.88—28.13
Dec. 31, 1960	21,000	15.89—19.52	25.94—31.44
Mar. 31 1961	2,100	15.89	32.31
June 30, 1961	14,700	15.89	37.50—38.00
Aug. 4, 1961	45,465	15.89—19.52	36.63
	102,297		

During the same period options expiring April 30, 1968 to purchase 6,000 shares at $19.38 per share and 16.000 shares at $23.13 per share were granted to all officers and directors as a group, the price per share being the market price on the date options were granted.

During February 1961 Mr. Willey sold 1,000 shares of Martin Common Stock, the net proceeds of which sale amounted to $34,555.42. This sale was within less than 6 months of the date when he exercised an option to purchase 1,050 shares (2,100 shares after giving effect to the 2 for 1 stock split effected on February 10, 1961 for stockholders of record January 20, 1961) and under the provisions of Section 16(b) of the Securities Exchange Act of 1934 any profit realized from such sale inures to and is recoverable by the Company. Based on the provisions of Rule X 16B-6 of the Securities and Exchange Commission the profit on the sale amounted to $10,119.82. Appropriate steps are being taken by the Company to recover the short term profit.

The number of shares issued and the price per share have been adjusted for stock dividends subsequent to the issuance of the respective stock options.

Subsequent to June 30, 1961, Martin has granted options or agreed to grant options to 2 employees other than officers and directors, to purchase in the aggregate 10,000 shares of its Common Stock at the closing market price on the date of the grant. After the effective date of the consolidation no further options will be granted under the Stock Option Plans of Martin. No shares of Common Stock will be reserved by the Consolidated Company for issuance upon options in lieu of the 19,000 shares of Common Stock of Martin which were still reserved for the granting of options when its plans terminate on the effective date of the consolidation.

All of the foregoing transactions reflect the 2-for-1 stock split effected on February 10, 1961, for stockholders of record January 20, 1961.

DESCRIPTION OF COMMON STOCK OF MARTIN

The only class of capital stock of Martin authorized and outstanding is the Common Stock without par value which has exclusive voting rights. The holders of Common Stock are entitled to receive such dividends as are declared by the Board of Directors out of any funds of Martin legally available therefor and are entitled to share pro rata in the distributable assets of Martin in the event of any liquidation, dissolution or winding up of Martin. Martin may not declare any dividend or make any distribution on its shares of stock for value, or permit a Subsidiary to purchase, redeem or otherwise acquire or retire for value any shares of stock of Martin, if upon giving effect thereto the aggregate amount expended for such purposes subsequent to December 31, 1957, shall exceed the sum of (a) the accumulated consolidated earnings (or deficit) of Martin and its Subsidiaries earned subsequent

to December 31, 1957 (without taking into consideration any net refunds made by Martin under the Renegotiation Act of 1951, for periods prior to 1958), (b) the aggregate net consideration realized from the sale after December 31, 1957, of stock of Martin, (c) the aggregate net consideration realized from the sale after December 31, 1957, of any indebtedness of Martin which has been converted into shares of stock of Martin subsequent to December 31, 1957, and (d) the sum of $5,000,000. Each holder of Common Stock is entitled to one vote for each share of stock outstanding in his name. Without assent or other action of the stockholders, the Board of Directors may from time to time receive subscriptions for or sell any or all of the then unissued shares of Common Stock, whether the same be any of the originally authorized shares or any increase thereof, and shall be under no obligation to offer the same to existing stockholders. In the opinion of Counsel for Martin, the presently outstanding shares of Common Stock are, and the shares to be issued on exercise of the Warrants to purchase shares of Common Stock issued November 1, 1958, will upon compliance with the terms of the Warrants be fully paid and nonassessable.

DESCRIPTION OF COMMON SHARES AND CLASS B COMMON SHARES OF AMERICAN-MARIETTA

Certain provisions applicable to the Common Shares and the Class B Common Shares of American-Marietta are hereafter summarized. Such summary does not contain all of the terms and provisions applicable to said shares and no summary and no effect is given as to the provisions applicable to the 5% Cumulative Preferred Shares because those shares will be redeemed prior to the special meeting of stockholders of American-Marietta.

Dividends

Dividends may be paid on Common Shares and Class B Common Shares out of any funds legally available for such purpose when and as declared by the Board of Directors, except that no dividends may be declared or paid on Class B Common Shares in any year unless an equal amount plus $2 is paid for that year on the Common Shares, and except that any dividend or distribution on the Common Shares in Common Shares or on the Class B Common Shares in Class B Common Shares may be made only so long as there is no greater proportionate increase in the number of Class B Common Shares outstanding than in the Common Shares outstanding as a result of such dividend or distribution.

The terms of the Unsecured Notes referred to under the caption "Capitalization" of American-Marietta payable to insurance companies set forth certain minimum requirements as to consolidated working capital and restrict the payment of cash dividends and purchases or other retirements of Capital Shares. In this connection, reference is made to Note "C" to Financial Statements.

Voting Rights

The holder of each outstanding share regardless of class is entitled to one vote for each share held on each matter submitted to a vote at a meeting of shareholders and may cumulate votes for the election of directors.

Liquidation Rights

In the event of any dissolution, liquidation or winding up, the remaining assets of the Company shall be distributed to the holders of the Common Shares of both classes, without preference between the holders of the Common Shares and Class B Common Shares. Neither a merger nor consolidation of the Company with or into any other corporation, nor a reorganization, nor a purchase or redemption of all or a part of the outstanding shares of any class, nor the sale of the property and business of the Company substantially as an entirety, shall be considered a liquidation or winding up of the Company.

Preemptive Rights

No holder of any shares of any class of the Company has any right, as such holder, to purchase or otherwise acquire any shares of any class of the Company, now or hereafter authorized, of any se-

curities convertible into any such shares, or warrants or other instruments to subscribe for or otherwise acquire any such share, whether the same be unissued or issued and thereafter acquired by the Company.

Conversion Rights

Under the Articles of Incorporation of the Company, the Class B Common Shares are convertible, subject to the restrictions of such conversion set forth in the Articles of Incorporation, into Common Shares on a share for share basis. The conversion rights of certain of these shares are further restricted by an Agreement dated November 1, 1958, between Grover M. Hermann, Shirley Hermann and Robert Hermann. At this date 340,523 Class B Common Shares are eligible for conversion and the remaining shares are subject to the conversion restrictions of the Agreement and may not be converted until they become eligible for conversion thereunder as follows: 62,500 shares on each January 1 and July 1 to and including July 1, 1969. The conversion restrictions terminate completely on January 1, 1970. The agreement provides that the shares eligible for conversion thereunder shall be proportionately increased in the event of stock dividends, stock splits or other increases in the outstanding Class B Common Shares; that the restrictions of the Agreement shall continue in effect with respect to the shares subject thereto irrespective of any transfers of shares by the original parties; and that the Agreement shall be irrevocable except that it may be amended or terminated with the consent of the holders of not less than ⅔ of the outstanding Class B Common Shares, as a class, and of the holders of not less than ⅔ of the outstanding Common Shares, as a class.

The Agreement further provides that if, as a result of certain mergers or consolidations or acquisitions of assets, the persons who were the shareholders of the Company immediately prior to any such transaction shall not be or become the holders of shares representing at least 60% of the voting power of all shares, and at least 50% of each class of shares (other than Preferred Shares, as defined) of the Company, or of the acquiring or surviving corporation, outstanding immediately after, or issuable as a part of, such transaction, the conversion restrictions imposed by the Agreement may be modified or terminated by the holder or holders of not less than 60% of the then outstanding Class B Common Shares subject to the Agreement.

DESCRIPTION OF STOCK OF CONSOLIDATED COMPANY

Dividends

After cumulative dividends have been paid at the rate of 4½% on the Preferred Stock, dividends may be paid on the Common Stock, when and as declared by the Board of Directors and subject to the limitations provided in the terms of the Preferred Stock and the 5½% Sinking Fund Debentures and in A-M's long term notes. See footnotes to Capitalization of Consolidated Company and to Financial Statements of the Constituent Companies in this Proxy Statement.

Voting Rights

The holders of Common Stock will be entitled to one vote per share, but will not have cumulative voting rights. The holders of Preferred Stock will have no voting rights except as specifically provided by law and except that in the event of default in payment of dividends on the Preferred Stock in an amount equal to four quarterly dividends or in the event of a default in the Sinking Fund provided for the Preferred Stock, the Preferred Stock will have the right to elect one-third of the board of directors.

Liquidation Rights

After payment to the Preferred Stock of $100 per share plus accrued dividends plus $5 per share if the liquidation is voluntary, the Common Stock will be entitled to all remaining assets of the Company properly distributable to stockholders upon any liquidation of the Consolidated Company.

Miscellaneous

The Preferred Stock is subject to redemption as a whole, but not in part, at any time after October 1, 1964, at $105 per share plus accrued dividends. The Preferred Stock is entitled to a sinking fund as set forth under "Capitalization of the Consolidated Company". The Company may not change its stock provisions in certain respects adverse to the Preferred Stock or issue or sell any additional Preferred Stock or stock ranking prior thereto or on a parity therewith without the consent of the holders of two-thirds of the Preferred Stock. There are no preemptive rights.

Reference is made to the stock terms of the Consolidated Company set forth in full in the Articles included in Appendix A.

TAX CONSEQUENCES

In the opinion of counsel for the constituent companies the consolidation will not result in taxable gain to either of the constituent companies and stockholders of the constituent companies will not realize any taxable gain or deductible loss as a result of the conversion of their stock into stock of the Consolidated Company. Gain or loss will be recognized to stockholders who may dissent and receive in cash the value of their stock in appraisal proceedings, and gain, if any, will be recognized to stockholders of Martin with respect to the proceeds of sale of any fractional share interest, but not in excess of the amount received upon such sale.

RIGHTS OF DISSENTING STOCKHOLDERS

Stockholders of Martin who object to the consolidation have such rights as objecting stockholders in respect of the proposed consolidation as are provided by Section 73 of Article 23 of the Annotated Code of Maryland (1957 Edition). Under this Section, objecting stockholders shall be entitled to demand and receive payment of the amount equal to the fair value of their stock. If such stockholders (1) shall prior to, or at, the special meeting of stockholders, file with Martin objection in writing to the proposed consolidation; (2) shall not vote in favor of the consolidation; (3) shall within twenty days after the Articles of Consolidation and Plan have been accepted for record by the Department of Assessments and Taxation of Maryland, make upon the Consolidated Company written demand for payment for his stock, stating the number and class of shares for which payment is demanded. Any stockholder, who fails to comply with the requirements of this Section within the time specified, shall be bound by the terms of the consolidation, merger or transfer. Merely voting against, or a direction in a proxy to vote against, the adoption of the Articles of Consolidation and Plan will not comply with the conditions required of objecting stockholders by Section 73 of Article 23 of the Annotated Code of Maryland (1957 Edition).

The Consolidated Company must deliver or mail to each objecting stockholder written notice of the date of acceptance for record of the Articles of Consolidation and Plan by the Department of Assessments and Taxation of Maryland, and may also deliver or mail to each such stockholder a written offer to pay for his stock at a price deemed to be the fair value thereof.

Within fifty days after the acceptance of the Articles of Consolidation and Plan for record by the Department of Assessments and Taxation of Maryland, either the Consolidated Company or any objecting stockholder who has not received payment for his stock may petition a court of equity in the City of Baltimore to determine the fair value of such stock. If such court finds that any objecting stockholder is entitled to have the value of the stock determined, it shall appoint three disinterested appraisers to determine the fair value of such stock. Such value shall be determined as of the close of business on the day of the stockholder's vote on the Articles of Consolidation and Plan to which objection was made, excluding any appreciation or depreciation, directly or indirectly, consequent upon such action or the proposal thereof. The appraisers are required to file a written report of their findings as to the fair value of the stock of the objecting stockholder, and the statute provides for appropriate action to be taken by the court in relation to such report of the appraisers.

The costs of valuation proceedings, which will include the costs of making the appraisal, are determined by the Court and will be assessed against the Consolidated Company; provided, that all or any part of the costs may be apportioned and assessed as the Court deems equitable against any or

all of the objecting stockholders parties to the proceedings, if, taking into consideration the price which the Consolidated Company offered for such stock, the financial statements and other information furnished, and such other circumstances as the Court deems relevant, the Court finds that the action of the stockholders, in failing to accept the offer was arbitrary and vexatious or not in good faith.

OTHER MATTERS

Vote needed to approve Proposed Consolidation

The affirmative vote of a majority of the outstanding shares is required to authorize the proposed consolidation.

Voting Rights

As of the close of business on July 31, 1961, Martin had outstanding 6,257,739 full shares of Common Stock and Scrip Certificates for 10,901 tenths of a share. Shareholders are entitled to one vote for each full share registered in their names. There are no classes of stock of Martin other than Common Stock. Shareholders of record at the close of business on August 30, 1961, the record date fixed by the Board of Directors, will be entitled to vote at the meeting.

Miscellaneous

The Management knows of no business constituting a proper subject for action by the stockholders which will be presented for consideration at the meeting other than that shown above.

The proxies are solicited by the Management of Martin and the cost of such solicitation has been or will be paid by Martin. In addition to solicitation by mail, arrangements may be made with brokerage houses and other custodians, nominees, and fiduciaries to send proxy material to their principals, and Martin may reimburse them for their expense in so doing. Martin has retained Georgeson and Company of New York City to aid in the solicitation of proxies at a cost estimated to be about $3,000. To the extent necessary in order to assure sufficient representation, officers and regular employees of Martin may request the return of proxies personally, by telephone or telegram. The extent to which this will be necessary depends entirely upon how promptly proxies are received, and stockholders are urged to send in their proxies without delay.

Any proxy given pursuant to this solicitation may be revoked by the person giving it at any time before its exercise. The shares of Martin's outstanding Common Stock represented by each proxy received before the Special Meeting and not revoked will be voted in favor of the proposed Consolidation Agreement and Plan set forth in the accompanying Notice of Special Meeting of Stockholders and in this statement, unless the proxies are instructed in the proxy to do otherwise.

W. L. Lucas, *Secretary*

August 30, 1961

IMPORTANT

TO INSURE REPRESENTATION AT THE SPECIAL MEETING, STOCKHOLDERS ARE REQUESTED TO SIGN AND MAIL PROMPTLY THE ACCOMPANYING PROXY FOR WHICH A RETURN ENVELOPE IS PROVIDED. NO POSTAGE IS REQUIRED IF MAILED IN THE UNITED STATES. IF YOU DO ATTEND THE MEETING, YOU MAY VOTE THERE IN PERSON SHOULD YOU SO DESIRE.

(This Page Intentionally Left Blank.)

OPINION OF INDEPENDENT CERTIFIED PUBLIC ACCOUNTANTS

Board of Directors,
The Martin Company,
Baltimore, Maryland

We have examined the balance sheet of The Martin Company as of December 31, 1960, and the related statements of earnings, additional paid-in capital and earnings reinvested for the five years then ended. Our examination was made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances; although we were unable to obtain satisfactory confirmation of accounts receivable from the Government, we satisfied ourselves as to these accounts by other means.

In our opinion, subject to such adjustments (which neither we nor the Company are able to evaluate) as may be required as a result of renegotiation as described in Note A, the accompanying balance sheet and statements of earnings (set forth in the Proxy Statement under the heading "Statement of Earnings"), additional paid-in capital and earnings reinvested present fairly the financial position of The Martin Company at December 31, 1960, and the results of its operations for the five years then ended, in conformity with generally accepted accounting principles applied on a consistent basis.

TOUCHE, ROSS, BAILEY & SMART

THE MARTIN COMPANY

NOTES TO FINANCIAL STATEMENTS

(A) Renegotiation:

See Note (A) to Statement of Earnings included elsewhere in this Proxy Statement.

(B) Inventories:

Title to inventories in the amount of approximately $7,600,000 at June 30, 1961 and $8,100,000 at December 31, 1960 had passed to the United States Government as consideration for progress payments. Material, labor and other costs incurred on contracts in progress less estimated costs applied to deliveries, not in excess of realizable value, used in determining cost of sales for each of the six years ended December 31, 1960 were, respectively, $82,524,902; $55,610,080; $39,168,843; $43,060,212; $36,374,520; $15,207,678 and for the six months ended June 30, 1961, $15,978,344.

(C) Debentures:

Sinking fund provisions of the Debentures require annual redemptions of $2,250,000. Among other restrictions under the Debenture Agreement, $14,514,499 of the earnings reinvested at December 31, 1960 and $13,707,517 of the earnings reinvested at June 30, 1961 were not available for the payment of dividends.

(D) Shares of capital stock were reserved for issuance as follows:

	12/31/60	6/30/61
(a) At a price of $7.47 per share at December 31, 1960 and $3.74 at June 30, 1961 upon presentation of capital stock purchase warrants expiring April 10, 1962, issued in connection with the sale of Ten-Year 4% Convertible Subordinated Notes	6	12
(b) Upon exercise at $40.00 per unit (consisting of 1.05 shares at December 31, 1960 and 2.10 shares at June 30, 1961) to and including November 1, 1963, and at $45.00 per unit thereafter to and including November 1, 1968, of warrants issued in connection with the Company's 5½% Sinking Fund Debentures	210,000	409,435
(c) Under a restricted stock option plan for officers and other key employees	134,792	232,199
Total	344,798	641,646

(E) Stock Options

In 1952 and 1958 stock option plans for officers and key employees were approved by the stockholders providing for the granting of options to purchase 200,000 and 140,000 shares respectively of the Company's capital stock. The plans provided that the number of shares and the issue price were subject to adjustments as might be necessary to protect the optionee against dilution. Accordingly, because of stock dividends declared and a 2 for 1 stock split subsequent to granting of options, the total number of shares subject to option under the 1952 plan was increased to 225,930 and under the 1958 plan to 265,680, and the effect of such adjustments is reflected in the information presented below. The option price under both plans is the closing price of the Company's stock on the New York Stock Exchange on the day when the particular option is granted; options may not expire more than ten years from the date of grant, nor may they be exercised in less than one year from the date of grant under the 1952 plan nor two years under the 1958 plan.

The number of shares with respect to which options under the plans were granted through June 30, 1961 and the years that such options became or will become exercisable, are as follows:

Date of Grant	Date Exercisable	Number of Shares	Option Price Per Share	Option Price Total	Market Quotations at Date Exercisable Per Share	Market Quotations at Date Exercisable Total
1952	1954–1957	95,877	$ 8.04– 9.75	$ 828,750	$18.63–43.50	$3,412,868
1952	1953	75,675	9.66–10.63	799,531	13.75	1,034,687
1953	1954	18,300	11.03–13.38	215,469	24.88–28.63	418,281
1955	1956	18,048	12.15–28.13	360,000	34.00	456,960
1957	1958	16,030	18.69–39.25	387,113	32.13–33.25	318,419
1958	1960	154,980	15.89–33.10	2,838,375	44.25–56.88	3,973,331
1959	1961	14,700	18.39–46.91	317,500		
1960	1962	64,000	19.00–56.63	1,400,625		
1961	1963	10,000	32.62–38.00	357,750		
		467,610		$7,505,113		

Since inception of the plans through June 30, 1961, options under the plans were exercised as follows:

Year Exercised	Number of Shares	Option Price Per Share	Option Price Total	Market Quotations at the various dates Options were Exercised Per Share	Market Quotations at the various dates Options were Exercised Total
1953	1,350	$10.63	$ 14,344	$14.63–15.88	$ 19,869
1954	89,650	$ 9.75–13.38	951,281	19.38–33.00	2,389,868
1955	16,500	8.86–12.16	152,688	28.13–38.38	486,613
1956	62,948	8.44–11.58	547,688	40.88–43.13	2,578,197
1957	18,742	8.04–25.51	178,438	42.38–46.63	831,457
1958	2,094	11.03–25.51	35,875	31.75–33.25	69,157
1959	4,116	25.51–39.25	129,156	42.75–59.75	219,766
1960	29,985	24.30–39.05	914,700	38.75–63.88	1,681,382
1961	34,026	12.12–31.79	605,738	31.63–65.25	1,342,702
	259,411		$3,529,908		$9,619,011

At June 30, 1961, options not yet exercised under the plans were as follows:

Date of Grant	Date Exercisable	Number of Shares	Option Price Per Share	Option Price Total	Market Quotations at Date of Grant Per Share	Market Quotations at Date of Grant Total
1955	1956	4,524	$12.12	$ 54,844	$12.12	$ 54,844
1957	1958	10,815	$18.69–19.52	205,024	$18.69–19.52	205,024
1958	1960	108,360	15.89–16.55	1,722,837	15.89–16.55	1,722,837
1959	1961	10,500	19.82–23.45	234,125	19.82–23.45	234,125
1960	1962	64,000	19.00–28.31	1,400,625	19.00–28.31	1,400,625
1961	1963	10,000	32.63–38.00	357,750	32.63–38.00	357,750
		208,199		$3,975,205		$3,975,205

Capital stock issued upon exercise of options was recorded at amounts received; no charges have been reflected in income with respect to stock options. Options cancelled have been reflected by reducing the number of shares originally covered by options.

(F) On January 9, 1961 the Certificate of Incorporation was amended to change the previously authorized 6,000,000 shares of capital stock of the Company to 12,000,000 shares of common stock without par value. A 2 for 1 stock split was effected on February 10, 1961 for stockholders of record on January 20, 1961.

(G) **Pensions:**

A pension plan was established for employees as of July 1, 1943, providing for pension payments and death benefits through an annuity contract with a legal reserve insurance company. Effective May 1, 1951, additional pension plans were established for hourly employees providing maximum benefits, as now amended, of $67.50 per month, reduced by any retirement benefits accrued under the earlier plan. Maximum benefits under the latter plans are payable after 30 years of credited service with the Company and retirement at or after age 65. Disability benefits are likewise provided. Unfunded past service costs under the latter plans estimated to be $5,179,000 at December 31, 1960 and $8,030,000 at June 30, 1961 are being funded over a period not to exceed 30 years. The earlier pension plan has been amended so as to cover salaried employees only, providing at or after age 65 for monthly benefit payments based upon compensation and length of service. The plans are non-contributory. The aggregate cost of these plans for 1960 was $5,209,984 and it is estimated the aggregate cost of these plans for 1961 will be approximately $5,900,000. The Company has the right to discontinue these plans at any time, except that it has agreed not to change or terminate the Pension Plans for hourly paid employees prior to December 31, 1963.

(H) **Property, plant and equipment:**

The cost of facilities which are owned by the Company, other than those covered by certificates of necessity, is depreciated over estimated useful lives on a straight-line basis for assets acquired prior to January 1, 1954 and on a sum of the years-digits basis for assets acquired after that date, as permitted by the Internal Revenue Code.

These rates may be summarized as follows:

Class of assets	Rate of depreciation
Building and building equipment	2% to 10%
Other land improvements	4% to 11¼%
Machinery and equipment	5% to 25%
Office equipment	6⅔% to 10%
Automobiles, trucks and tractors	25%
Airplanes and boats	20% to 25%

Amortization is computed in accordance with the provisions of the Internal Revenue Code on assets covered by certificates of necessity.

Maintenance and repairs are charged to income as incurred and expenditures for major renewals and betterments are capitalized.

At the disposal or retirement of properties, the difference between the depreciated value of assets and the amount realized is charged against, or credited to, revenue.

Effective with December 31, 1953, fully depreciated property, plant and equipment was eliminated from the accounts.

(I) Supplementary profit and loss information:

	Year Ended December 31,					(Unaudited) 6 Months Ended June 30,
	1956	1957	1958	1959	1960	1961

Rents	$1,123,739	$1,897,492	$2,039,383	$2,529,297	$ 3,518,589	$2,567,475
Royalties	729,990	94,750	—	—	—	—
	$1,853,729	$1,992,242	$2,039,383	$2,529,297	$ 3,518,589	$2,567,475

The major portion of the above charges has been charged to cost of sales. Amounts charged to other accounts were not material. There were no management or service contract fees.

ACCOUNTANTS' REPORT

Board of Directors
American-Marietta Company
Chicago, Illinois

We have examined the consolidated balance sheet of American-Marietta Company and consolidated subsidiaries as of November 30, 1960, and the related statements of consolidated income, additional capital and accumulated earnings for the period of five years then ended. Our examinations were made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances. The accounts of one company and its subsidiary for the years ended December 31, 1956, 1957, and 1958, and the accounts of another company and its subsidiaries for the years ended December 31, 1956, 1957, 1958, and 1959, were examined by other independent accountants, and the financial statements of these companies have been incorporated in the aforementioned consolidated financial statements in reliance on the reports, included elsewhere in this proxy statement, of such accountants.

In our opinion, based upon our examinations and the reports of the other accountants referred to above, the accompanying balance sheet and statements of income, additional capital and accumulated earnings present fairly the consolidated financial position of American-Marietta Company and consolidated subsidiaries at November 30, 1960, and the consolidated results of their operations for the period of five years then ended (including on a combined basis the operations of the merged companies referred to in Note A to the financial statements) in conformity with generally accepted accounting principles applied on a consistent basis.

ERNST & ERNST

ACCOUNTANTS' REPORT

Board of Directors
American-Marietta Company
Chicago, Illinois

We have examined the statements of consolidated earnings and retained earnings of Dewey Portland Cement Company and subsidiaries for the four years ended December 31, 1959. Our examination was made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances. We have not examined financial statements of the Company and subsidiaries for any period subsequent to December 31, 1959.

In our opinion, such financial statements (not shown separately herein) present fairly the results of operations of Dewey Portland Cement Company and subsidiaries for the four years ended December 31, 1959, in conformity with generally accepted accounting principles applied on a consistent basis.

PEAT, MARWICK, MITCHELL & CO.

ACCOUNTANTS' REPORT

Board of Directors
American-Marietta Company
Chicago, Illinois

We have examined the financial statements of Superior Stone Company and subsidiary for the three years ended December 31, 1958. Our examination was made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances.

In our opinion, the statements of income and accumulated earnings of Superior Stone Company and subsidiary (not shown separately herein) present fairly the results of operations of Superior Stone Company and subsidiary for the three years ended December 31, 1958, in conformity with generally accepted accounting principles applied on a basis consistent with that of the preceding year.
