Section 1 Introduction

This Semiannual Groundwater Monitoring Report (Report) has been prepared by Tetra Tech, Inc. (Tetra Tech), on behalf of Lockheed Martin Corporation (LMC) and presents the results of the Second Quarter 2010 and Third Quarter 2010 groundwater quality monitoring activities for the Beaumont Site 2 (Site) Groundwater Monitoring Program (GMP). The Site is located southwest of the City of Beaumont, Riverside County, California (Figure 1-1). Currently, the Site is inactive with the exception of ongoing investigative activities performed under Consent Order (HSA 88/89-034, amended January 1, 1991) with the Department of Toxic Substances Control (DTSC).

The objectives of this Report are to:

- Briefly summarize the Site history;
- Document the water quality monitoring procedures and results;
- Analyze and evaluate the water quality monitoring data generated.

This Report is organized into the following sections: 1) Introduction, 2) Summary of Monitoring Activities, 3) Groundwater Monitoring results, and 4) Summary and Conclusions. A brief description of the previous site environmental investigations and the current conceptual site model (CSM) can be found in Appendix A.

1.1 Site Background

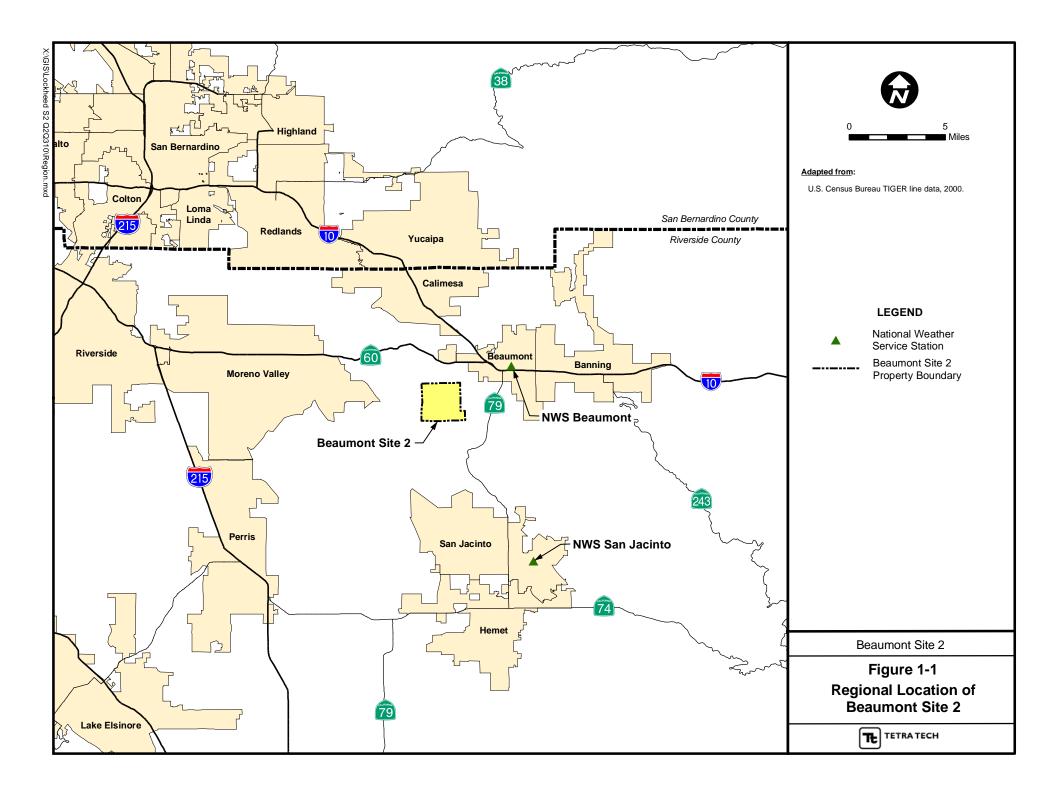

The Site is a 2,668 acre parcel located southwest of Beaumont, California. The parcels that comprise the Site were owned by individuals and the United States (U.S.) government prior to 1958. Between 1958 and 1960, portions of the Site were purchased by the Grand Central Rocket Company (GCR) and utilized as a remote test facility for early space and defense program efforts. In 1960, Lockheed Aircraft Corporation (LAC) purchased one-half interest in GCR. GCR became a wholly-owned subsidiary of LAC in 1961. The remaining parcels of land that comprise the Site were purchased from the U.S. government between 1961 and 1964. In 1963, Lockheed Propulsion Company (LPC) became an operating division of LAC and was responsible for the operation of the Site until its closure in 1974. The Site was utilized by GCR and LPC from 1958 to 1974 for

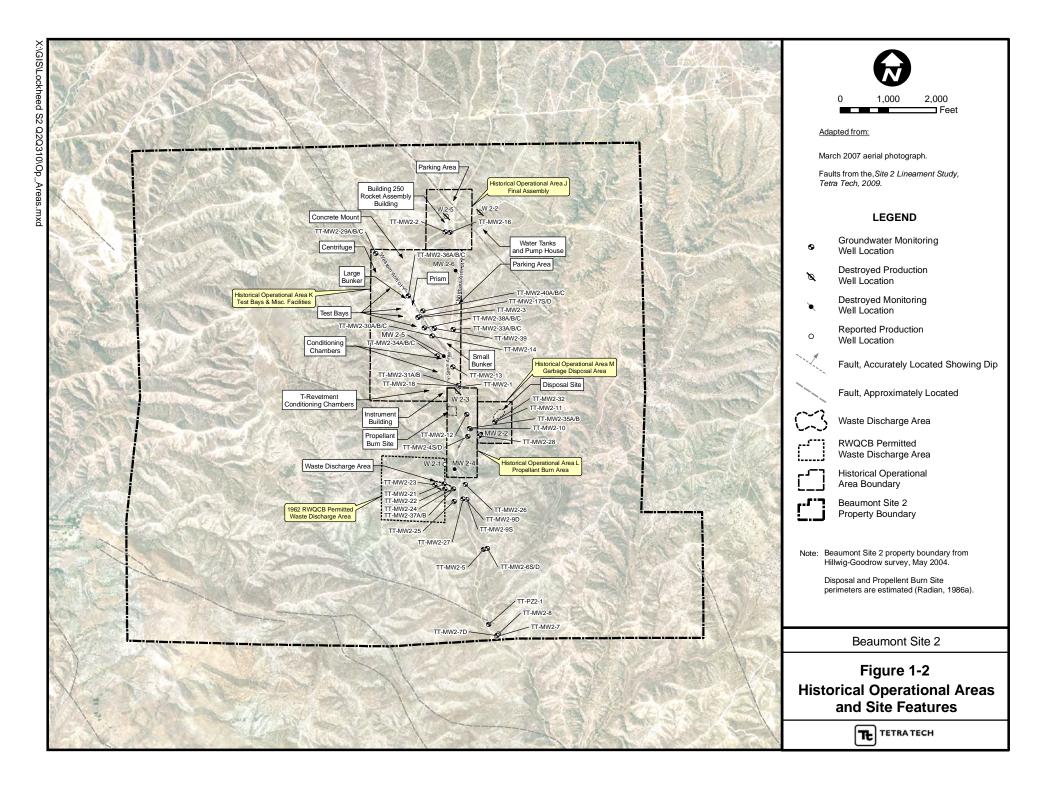

small rocket motor assembly, testing operations, propellant incineration, and minor disposal activities. Ogden Labs is known to have leased portions of the Site in the 1970s (Radian, 1986a).

In 1989, the DTSC issued a Consent Order requiring LMC to clean up contamination at the Site related to past testing activities (CDHS, 1989). Based on investigative and cleanup activities performed at the Site, the DTSC issued a no further remedial action letter to LMC in 1993.

Based on regulatory interest in perchlorate and 1,4-dioxane, a groundwater sample was collected from an inactive groundwater production well (identified as W2-3) at the Site in January 2003. The sample was analyzed for volatile organic compounds (VOCs), perchlorate, and 1,4-dioxane to determine the potential presence and concentration of those chemicals in groundwater. The analytical results indicated that VOCs and 1,4-dioxane were not present at or above their respective method detection limits (MDLs). However, perchlorate was reported at a concentration of 4,080 micrograms per liter (μ g/L), which exceeded the California Department of Public Health drinking water notification level (DWNL) which existed at that time of 6 μ g/L. In October 2007 the DWNL was replaced by the California Department of Public Health Maximum Contaminant Level (MCL). Based on the detection of perchlorate in the groundwater sample collected, the DTSC reopened the Site for further assessment.

Four primary historical operational areas have been identified at the Site (Figure 1-2). Each operational area was responsible for various activities associated with rocket motor assembly, testing, and propellant incineration. A brief description of each operational area follows.

Historical Operational Area J (Area J) –Final Assembly

Rocket motor casings with solid propellant were transported to Building 250 where final assembly of the rocket hardware was conducted. The building was used from 1970 to 1974 for final assembly and shipment of short range attack missile rocket motors. Rocket motor assembly operations included installation of the nozzle and headcap, pressure check of the motor, installation of electrical systems, and preparations for shipment. During plant closure in 1974, all usable parts of this facility were dismantled, taken off the Site, and sold (Radian, 1986a).

Historical Operational Area K (Area K) – Test Bays and Miscellaneous Facilities

The primary features included a large earthen structure known as the "Prism," conditioning chambers, a centrifuge, and four test bays and two associated bunkers.

The Prism was reportedly built between 1984 and 1990 and was used to test radar by General Dynamics (Tetra Tech, 2007a). Details concerning construction of the Prism are not available, but it appears to have been constructed with soils from near the test bays.

The conditioning chambers were used to examine the effects of extreme temperatures on rocket motors and to meet specification requirements (Radian, 1986a). A centrifuge was located in the northwestern portion of Area K, where rocket motors were tested in order to determine if the solid propellant would separate from its casing under increased gravitational forces.

Previously, only three test bays were known; however, a former employee reported during a recent interview that a fourth test bay, located north of the other three bays, was also previously used in Area K (Tetra Tech, 2009). The initial testing activities had a history of explosions that destroyed complete test areas, especially during the period when GCR operated at the Site (Radian, 1986a). While vestiges from three test bays are currently visible at the Site, the fourth was reportedly destroyed by such an explosion during testing. Also reportedly, after motor failure, the area was checked to recover unburned propellant.

Historical Operational Area L (Area L) – Propellant Burn Area

Solid propellant was reportedly transported to the burn area and set directly on the ground surface for burning (Radian, 1986a). No pits or trenches were dug as part of the burning process. The solid propellant was saturated with diesel fuel to initiate combustion. Reportedly, the solid propellant would burn rapidly. There is no evidence or physical features that identify the precise location of burning activities, and previous site investigations (Tetra Tech, 2005; Tetra Tech, 2010b) found no evidence of significant contamination in Area L.

Historical Operational Area M (Area M) – Garbage Disposal Site

A garbage disposal area was located adjacent to a small creek at the Site (Radian, 1986a). Scrap metal, paper, wood, and concrete materials were disposed of at the disposal site by LPC. Hazardous materials, including explosives and propellants, were never disposed of at the disposal site by LPC according to employee interviews. Ogden Labs, a company that tested valves and explosive items, also reportedly used this site for disposal of hazardous waste. In 1972, a Lockheed Safety Technician was exposed to toxic vapors of unsymmetrical dimethyl hydrazine (u-DMH) from a pressurized gas container located within the disposal site. Based on potential exposure risks to occupants, LPC's safety group required Ogden Labs to take measures to remove any potentially hazardous materials at the disposal site. Shortly thereafter, a disposal company was contracted by Ogden Labs to clean up the disposal site (Radian, 1986a).

Waste Discharge Area (WDA)

In 2007, LMC discovered the existence of Santa Ana River Basin Regional Water Pollution Control Board Resolution 62-24, dated September 14, 1962. Resolution 62-24 prescribed requirements for the "discharge of industrial wastes (rocket fuel residuum) to excavated pits." The discharge area was described as two shallow basins protected by two-foot berms, located in a small canyon on the western side of Laborde Canyon, in the SW ¼ of the NW ¼ of Section 19, Township 3 South, Range 1 West, San Bernardino Baseline and Meridian. Resolution 62-24 further describes the wastes to be discharged as "residue remaining after the manufacturing refuse is burned," and indicates that amount of material to be discharged was "approximately 5,000 gallons per year."

The exact nature of the waste proposed for discharge is not clear from the Resolution 62-24. The description of the waste material suggests that the area may have been used for burning propellant; but the description of the quantity of material to be discharged suggests that the waste may have been liquid rather than solid. A 1961 aerial photograph shows the WDA as a large cleared area with roads leading to two circular structures, suggesting that the WDA was in use by 1961 (Tetra Tech, 2009a). Investigation of this area (Tetra Tech, 2007c; 2008a) found evidence for perchlorate impacts in both soil and groundwater.

Features remaining at the WDA include two roughly circular depressions surrounded by earthen berms, at the location of the circular structures identified in the 1961 aerial photograph.

Section 2 Summary of Monitoring Activities

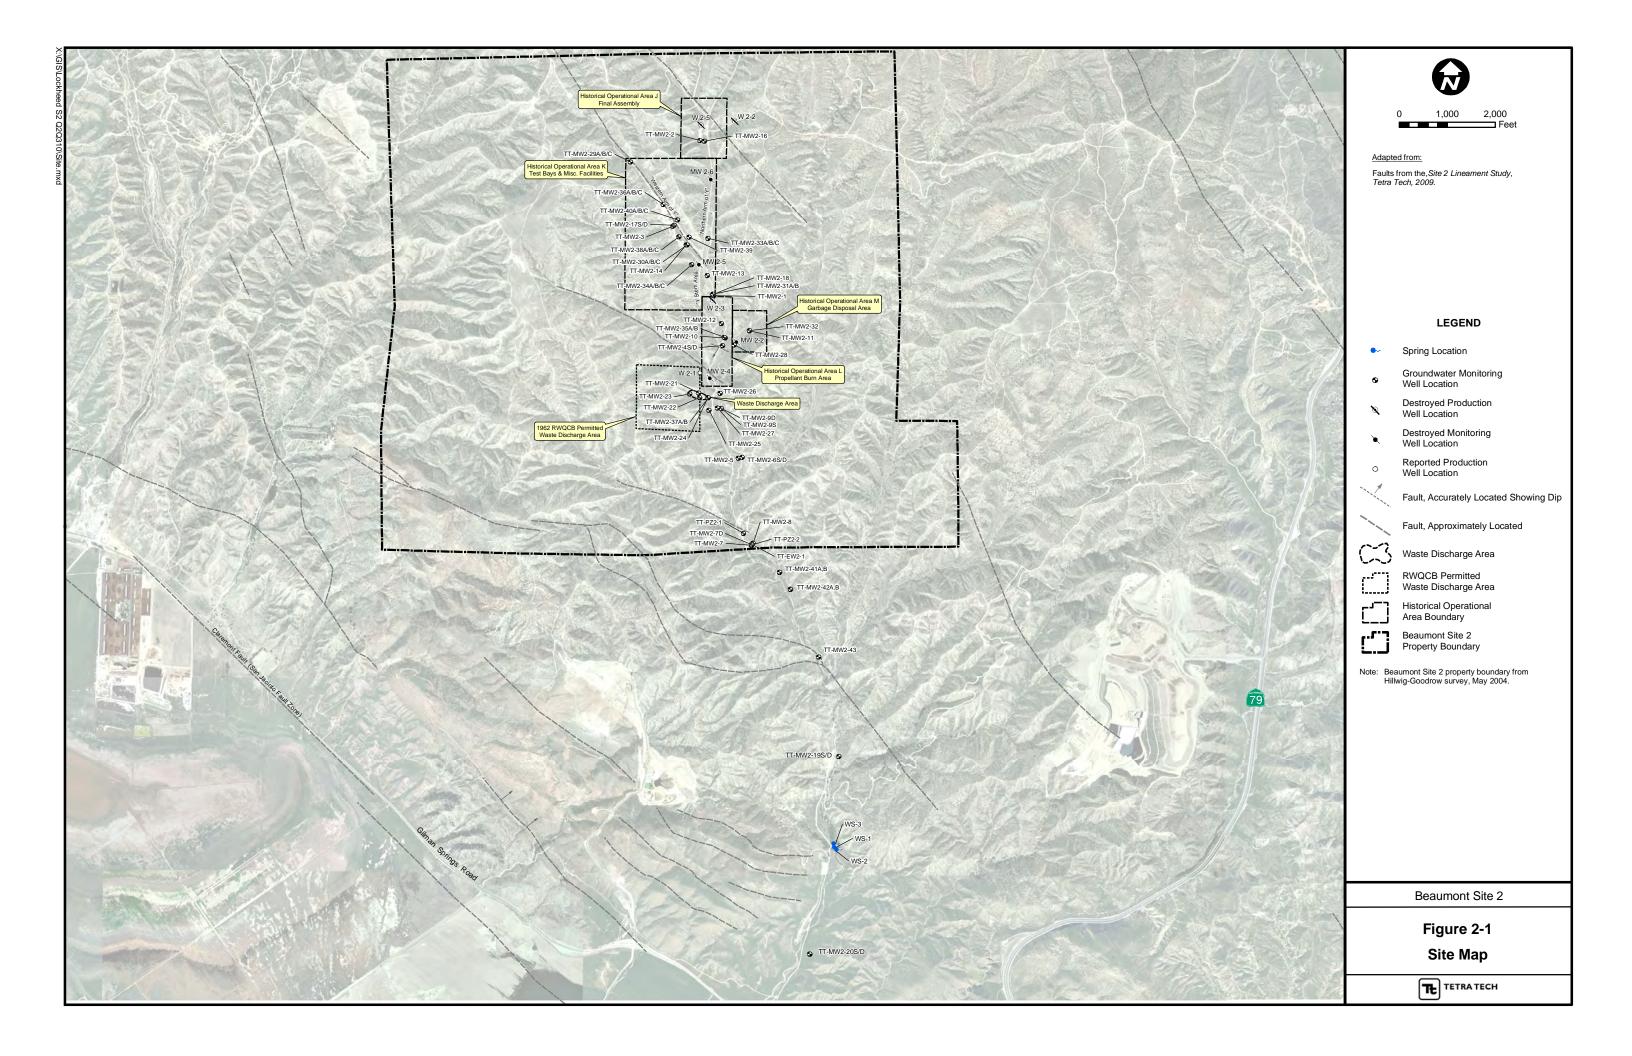

Section 2 summarizes the Second Quarter 2010 and Third Quarter 2010 groundwater monitoring events conducted at the Site. The results from these monitoring events are discussed in Section 3.

2.1 Groundwater Level Measurements

Groundwater level measurements are collected at the Site on a quarterly basis from all available wells. Water level measurements for 69 wells and two piezometers were proposed for Second Quarter 2010 and Third Quarter 2010. During Second Quarter 2010 groundwater level measurements were collected from 67 monitoring wells and two piezometers between 17 May 2010 and 18 May 2010. During Third Quarter 2010 groundwater level measurements were collected from 67 monitoring wells and two piezometers between 27 August 2010 and 30 August 2010. Two monitoring wells, TT-MW2-29A and TT-MW2-43, were found to be dry during both quarters. Figure 2-1 presents a site map showing the well locations. Copies of the field data sheets from the water quality monitoring events are presented in Appendix B. A summary of well construction details is presented in Appendix C.

2.2 Groundwater Sampling

The GMP has a quarterly, semiannual, and annual frequency. Both groundwater and surface water are sampled as part of the GMP. The annual event is the major monitoring event and the quarterly and semiannual events are smaller, minor events. All new wells are sampled quarterly for one year, after which they are evaluated and reclassified. The semiannual event includes horizontal extent, vertical distribution, increasing contaminant, and guard wells and occurs during the second and fourth quarter of each year. The annual monitoring event includes background wells and takes place during the second quarter of each year. The groundwater monitoring schedule is reviewed and modified as necessary annually during the Second Quarter groundwater monitoring event. Modifications are done in accordance with the approved Groundwater Sampling and Analysis Plan (SAP) (Tetra Tech, 2007b). Second Quarter 2010 and Third Quarter 2010 follow the schedule proposed in the Second and Third Quarter 2009 monitoring report (Tetra Tech, 2010a) which was presented to the DTSC in March 2010 and approved with no comments to the proposed schedule.

During the Second Quarter 2010 monitoring event 62 groundwater monitoring well samples, five private production wells and/or spring samples, and three surface water samples were collected between 3 May 2010 and 19 July 2010. One private spring and two monitoring wells, TT-MW2-29A and TT-MW2-43, were dry and could not be sampled. Additionally, the pump in one private production well was not operational and could not be sampled. During the Third Quarter 2010 monitoring event, six groundwater samples and two surface water samples were collected between 8 September 2010 and 10 September 2010. Tables 2-1 and 2-2 list the locations monitored for the Second Quarter 2010 and Third Quarter 2010 monitoring events, analytical methods, sampling dates, and Quality Assurance/Quality Control (QA/QC) samples collected. Figures 2-2 and 2-3 illustrate the well locations sampled for the Second Quarter 2010 and Third Quarter 2010 monitoring events, respectively. Groundwater sampling, analytical, and QA/QC procedures for the monitoring event were described in the Groundwater Monitoring Well Installation Work Plan (Tetra Tech, 2004a) and the SAP.

The following water quality field parameters were measured and recorded on field data sheets (Appendix B) during well purging activities: water level, temperature, pH, electrical conductivity (EC), turbidity, dissolved oxygen (DO) and oxidation/reduction potential (ORP). Measurement of water quality parameters was initiated when at least one discharge hose/pump volume had been removed and purging was considered complete when the above parameters had stabilized or the well was purged dry (evacuated). Stabilization of water quality parameters was used as an indication that representative formation water had entered the well and was being purged. The criteria for stabilization of these parameters are as follows: water level \pm 0.1 foot, pH \pm 0.1, and EC \pm 3%, turbidity < 10 nephelometric turbidity units (NTUs) (or \pm 10% if turbidity stabilizes at > 10 NTUs), DO \pm 0.3 mg/L and ORP \pm 10 mV. Sampling instruments and equipment were maintained, calibrated, and operated in accordance with the manufacturer's specifications, guidelines, and recommendations. Groundwater monitoring wells were purged and sampled using low-flow purging and sampling techniques with dedicated double valve sampling pumps or a portable bladder pump.

For the Second Quarter 2010 and Third Quarter 2010 monitoring events, every effort was made to collect groundwater samples in order of increasing perchlorate and TCE concentration. Samples were placed in appropriate EPA method specified containers. A sample identification label was affixed to each sample container, and sample custody was maintained by a chain-of-custody

record. Groundwater samples collected for the monitoring events were chilled and transported to E. S. Babcock & Sons, Inc., a state-accredited analytical laboratory, via courier, thus maintaining proper temperatures and sample integrity. Lockheed trip blanks (LTBs) were collected on each day of the monitoring events to assess potential cross-contamination of water samples while in transit. Lockheed equipment blanks (LEBs) were collected when sampling with non-dedicated equipment to assess cross-contamination potential of water samples via sampling equipment.

2.3 Surface Water Sampling

Storm water locations SW-01 through SW-07 are located in the ephemeral creek bed that runs through Laborde Canyon. Storm water runoff collects in the creek during periods of heavy precipitation and runs south through the Site and the former Wolfskill property, eventually crossing under Gilman Hot Springs Road. Water is present in the creek bed only during periods of heavy, prolonged precipitation. Surface water locations WS-1, WS-2 and WS-3 are spring locations on the former Wolfskill property. Water is generally present at one or more of these locations throughout the year.

During Second Quarter 2010, surface water samples were collected from three locations, WS-1, WS-2, and WS-3, and were analyzed for perchlorate. During Third Quarter 2010, surface water samples were collected from two locations, WS-1 and WS-2, and were analyzed for perchlorate. Surface water location WS-3 did not have flowing water so a sample was not collected during Third Quarter 2010. No other surface or storm water samples were collected during this reporting period. Figure 2-4 presents the surface and storm water sampling locations.

QA/QC - Quality assurance / quality control
MS / MSD- Matrix Spike / Matrix Spike Duplicate.

"-" Not analyzed NA - Not available.

2.4 Analytical Data QA/QC

The groundwater samples collected were analyzed using approved EPA methods. Since the analytical data were obtained by following EPA-approved method criteria, the data were validated using the EPA-approved evaluation methods described in the National Functional Guidelines (EPA, 2008 and EPA, 2010).

Quality control parameters used in validating data results include: holding times, field blanks, laboratory control samples, method blanks, duplicate environmental samples, spiked samples, and surrogate and spike recovery data.

2.5 Habitat Conservation

All monitoring activities were performed in accordance with the U.S. Fish and Wildlife Service approved Habitat Conservation Plan (HCP) [USFWS, 2005] and subsequent clarifications (LMC, 2006a and 2006b) of the HCP. Groundwater sampling activities were conducted with light duty vehicles and were supervised by a USFWS approved biologist as specified in the Low Effect HCP.

Section 3 Groundwater Monitoring Results

The results of the Second Quarter 2010 and Third Quarter 2010 groundwater monitoring events are presented in the following subsections. These subsections include tabulated summaries of the groundwater elevation and water quality data, groundwater elevation maps, and analyte results figures.

3.1 Groundwater Elevation

Based on the groundwater levels measured during the Second Quarter 2010 and Third Quarter 2010 monitoring events, groundwater elevations at the Site range from about 2,075 feet above mean seal level (msl) at TT-MW2-16, located in the northern portion of the Site, to about 1,819 feet msl at TT-MW2-8, located in the southern portion of the Site. Depth to first groundwater ranged from about 122 feet bgs at TT-MW2-29B to about 17 feet bgs at TT-MW2-8. A tabulated summary of groundwater depths and elevations is presented in Table 3-1. Changes in groundwater elevations from the previous monitoring event for wells monitored for the Second Quarter 2010 and Third Quarter 2010 monitoring events are shown on Figures 3-1 and 3-2, respectively, and hydrographs for individual wells are presented in Appendix D.

When compared to First Quarter 2010, groundwater elevations during Second Quarter 2010 decreased an average of 0.22 feet. When compared to Second Quarter 2010, groundwater elevations during Third Quarter 2010 increased an average of 0.30 feet. Average changes in groundwater elevations by area for wells monitored during the Second Quarter 2010 and Third Quarter 2010 monitoring events are shown in Table 3-2.

3.2 Groundwater Flow

Groundwater contour maps for first groundwater screened wells from Second Quarter 2010 and Third Quarter 2010 groundwater levels are presented in Figure 3-3 and Figures 3-4 respectively. Hydrographs for individual wells are presented in Appendix D.

Table 3-1 Groundwater Elevation Data - Second Quarter 2010 and Third Quarter 2010

			Secon	d Quarter 2010		Third Quarter 2010			
Well ID	Measuring Point Elevation (feet msl)	Date Measured	Depth to Water (from Measuring Point, feet)	Groundwater Elevation (feet msl)	Groundwater Elevation Change from First Quarter 2010 (feet)	Date Measured	Depth to Water (from Measuring Point, feet)	Groundwater Elevation (feet msl)	Groundwater Elevation Change from Second Quarter 2010 (feet)

3.3 Groundwater Gradients

Horizontal groundwater gradients are calculated using a segmented path from well to well that approximates the overall site flowline. The horizontal gradient is a measure of the change in the hydraulic head divided by the distance between wells (i.e., the slope of the water table). The average horizontal groundwater gradient calculated between TT-MW2-16 and TT-MW2-6S from the Second Quarter 2010 and Third Quarter 2010 groundwater monitoring events for the shallow Quaternary Alluvium and weathered San Timoteo Formation (QAL/wSTF) screened wells was 0.030 ft/ft. The horizontal groundwater gradient calculated between TT-MW2-2 and TT-MW2-6D for the Second Quarter 2010 and Third Quarter 2010 groundwater monitoring events for the deeper San Timoteo Formation (STF) screened wells was 0.029 ft/ft.

Vertical groundwater gradients are calculated from individual clusters of wells. Well clusters are used to measure the differences in static water level at different depths within the aquifer. The vertical gradient is a comparison of static water level between wells at different depths within the aquifer and is an indication of the vertical flow, (downward - negative gradient, upward - positive gradient), of groundwater. Vertical groundwater gradients at the Site are generally downward. The vertical gradients range from negative 0.29 at well cluster TT-MW2-4S and 4D located in Area L, to positive 0.19 at well cluster TT-MW2-19S and 19D located on the former Wolfskill property. A summary of calculated horizontal and vertical groundwater gradients is presented in Table 3-3. A complete listing of historical horizontal and vertical groundwater gradients and associated calculations is presented in Appendix E.

3.4 Analytical Data Summary

Groundwater and spring samples collected during the Second Quarter 2010 monitoring event were analyzed for perchlorate. Select wells were also sampled for VOCs, NDMA, 1,4-dioxane, hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), total metals, dissolved metals, general minerals, and natural attenuation parameters. VOCs and perchlorate are contaminants of potential concern at the Site. During the Third Quarter 2010 monitoring event, groundwater and spring samples were analyzed for perchlorate.

Summaries of validated laboratory analytical results for analytes detected above their respective MDLs during the Second Quarter 2010 monitoring event are presented in Tables 3-4 through 3-6. Summaries of validated laboratory analytical results for analytes detected above their respective MDLs during the Third Quarter 2010 monitoring event are presented in Table 3-7. A complete list of the analytes tested along with validated sample results by analytical method are provided in Appendix F. VOC and perchlorate sample results above the published MCL (federal or state, whichever is lower) or DWNL are indicated by bold type in Tables 3-4 through 3-7. Tables 3-8 and 3-9 present summary statistics for validated organic and inorganic analytes detected during the monitoring events. Laboratory analytical data packages, which include all environmental, field QC, and laboratory QC results, are provided in Appendix G. A consolidated laboratory data summary table is presented in Appendix H.

3.4.1 Data Quality Review

The quality control samples were reviewed as described in the Revised Groundwater Sampling and Analysis Plan (Tetra Tech, 2003b). The data for the groundwater sampling activities were contained in analytical data packages generated by E.S. Babcock & Sons, Inc. These data packages were reviewed using the latest versions of the National Functional Guidelines for Organic and Inorganic Data Review documents from the EPA (EPA, 2008 and 2005).

Preservation criteria, holding times, field blanks, laboratory control samples (LCS), method blanks, duplicate environmental samples, spiked samples, and surrogate and spike recovery data were reviewed. Within each environmental sample the sample-specific quality control spike recoveries were examined. These data examinations include comparing statistically calculated control limits to percent recoveries of all spiked analytes and duplicate spiked analytes. Relative Percent Difference (RPD) control limits are compared to actual spiked (MS/MSD) RPD results.

Surrogate recoveries were examined for all organic compound analyses and compared to their control limits.

Environmental samples were analyzed by the following methods: Method SM2320B for alkalinity, Method SM4500B for nitrite, Method E200.7 for Manganese, Method AM23G for volatile fatty acids, Method AM20GAX for hydrogen, Method E300.0 for nitrate, sulfate, and chloride, Method E521 for low level NDMA, Method E332.0 for perchlorate and chlorate, Method SM5310 for total and dissolved organic carbon, Method RSK-175 for methane, ethane, ethene, Method SW8270C SIM for low level 1,4-dioxane, Method SW6010B for iron, Method SW6020 for metals and Method SW8260B for VOCs. Unless otherwise noted below, all data results met required criteria, are of known precision and accuracy, did not require qualification, and may be used as reported.

Method E521 for low level NDMA had surrogate recovery errors that affected two out of fourteen samples and qualified as estimated 15.4 percent of the total E521 data. The data qualified as estimated is usable for the intended purpose. Additional sample volumes will be collected for future E521 analyses so the laboratory can perform corrective action to mitigate surrogate recovery errors.

Method SW8260B for VOCs had laboratory blank contamination that caused 0.1 percent of the total SW8260B data to be qualified for blank contamination. Blank qualified data is generally considered not detected.

In addition to being detected by method SW8270C SIM, if high enough concentrations are encountered, 1,4-dioxane will also be detected by Method SW8260B. However, Method SW8270C SIM is a more reliable method for measuring 1,4-dioxane at the required detection limits than Method SW8260B. Therefore, where available, the SW8270C SIM result will be used in data presentation and analysis as the best and correct result for the analyte. All data is validated and reported in Appendix F

Method RSK-175 for methane, ethane, and ethene had method blank contamination that caused 6.5 percent of the total RSK-175 data to be qualified for blank contamination. Blank contaminated data should be considered not detected.

Method E300.0 for anions had errors that qualified as estimated in the data listed below

• Four out of 68 nitrate samples (5.9 percent) had holding time errors (samples were analyzed outside of the 48-hour holding time but less than twice the holding time). The holding time errors were due to laboratory errors.

• One out of 68 sulfate samples (1.5 percent) was qualified as estimated due to low matrix spike recovery.

The E300 data qualified as estimated are usable for the intended purpose.

Method AM23G for volatile fatty acids had matrix spike recovery errors that qualified as estimated 0.9 percent of the total AM23G data. The data qualified as estimated is usable for the intended purpose. Method blank contamination qualified 4.3 percent of the total AM23G data. Data qualified for blank contamination is generally considered not detected.

Method SM5310 for dissolved organic carbon had field duplicate errors that qualified 2.5 percent of the total SM5310 data. The estimated data is usable for the intended purpose. Field blank contamination qualified 4.9 percent of the total SM5310 data. Data qualified for blank contamination is generally considered not detected.

Method E332.0 for perchlorate had matrix spike recovery errors that qualified as estimated 1.3 percent of the total E332.0 data. Data qualified as estimated is usable for the intended purpose. Field blank contamination qualified 1.3 percent of the total E322.0 data. Data qualified for blank contamination is generally considered not detected.

Method SW6020 for metals had method blank contamination qualified 4.3 percent of the total SW6020 data. Data qualified for blank contamination is generally considered not detected.

Notes: Only analytes positively detected in samples are presented in this table. For a complete list of constituents analyzed, refer to the laboratory data package.

μg/L - Micrograms per liter

ng/L - Nanograms per liter

NDMA - N-Nitrosodimethylamine

MCL - California Department of Public Health Maximum Contaminant Level.

DWNL - California Department of Public Health drinking water notification level.

(1) - DWNL

" - " MCL/DWNL not established.

Bold - MDL or DWNL exceeded.

NA - Not analyzed

< # - Method detection limit concentration is shown.

B - The sample result was less than 5 times blank contamination. Cross contamination is suspected.

J - The analyte was positively identified, but the concentration is an estimated value.

a - The analyte was found in the method blank.

b - The surrogate spike recovery was outside control limits.

 \boldsymbol{q} - $\;\;$ The analyte detected was below the Practical Quantitation Limit (PQL).

Table 3-4 Summary of Validated Detected Organic Analytes - Second Quarter 2010 (continued)

μg/L - Micrograms per liter

ng/L - Nanograms per liter NDMA - N-Nitrosodimethylamine

MCL - California Department of Public Health Maximum Contaminant Level.

DWNL - California Department of Public Health drinking water notification level.

(1) - DWNL

" - " MCL/DWNL not established.

Bold - MDL or DWNL exceeded.

NA - Not analyzed

< # - Method detection limit concentration is shown.

B - The sample result was less than 5 times blank contamination. Cross contamination is suspected.

J - The analyte was positively identified, but the concentration is an estimated value.

a - The analyte was found in the method blank.

b - The surrogate spike recovery was outside control limits.

q - $\;\;$ The analyte detected was below the Practical Quantitation Limit (PQL).

Table 3-5 Summary of Validated Detected Inorganic Analytes - Second Quarter 2010

Sample Name	Sample Date	Filter Status	Perchlorate ug/L	Arsenic mg/L	Barium mg/L	Cadmium mg/L	Cobalt mg/L	Chromium mg/L	Copper mg/L	Iron ug/L	Lead mg/L	Mercury ug/L	Manganese ug/L	Molybdenum mg/L	Nickel mg/L	Selenium mg/L	Vanadium mg/L	Zinc mg/L

Notes: Only analytes positively detected in samples are presented in this table. For a complete list of constituents analyzed, refer to the laboratory data package.

μg/L - Micrograms per liter mg/L - Milligrams per liter

MCL - California Department of Public Health Maximum Contaminant Level.

DWNL - California Department of Public Health drinking water notification level.

(1) - DWNL

" - " MCL/DWNL not established.

NA - Not analyzed.

Bold - MCL or DWNL exceeded.

< # - Method detection limit concentration is shown.</p>

B - The sample result was less than 5 times blank contamination. Cross contamination is suspected.

J - The analyte was positively identified, but the concentration is an estimated value.

a - The analyte was found in the method blank.

k - The analyte was found in a field blank.

q - The analyte detected was below the Practical Quantitation Limit (PQL).

Only analytes positively detected in samples are presented in this table. For a complete list of constituents analyzed, refer to the laboratory data package.

 μ g/L - Micrograms per liter

mg/L - Milligrams per liter

MCL - California Department of Public Health Maximum Contaminant Level.

DWNL - California Department of Public Health drinking water notification level.

(1) - DWNL

" - " MCL/DWNL not established.

NA - Not analyzed.

Bold - MCL or DWNL exceeded.

<# - Method detection limit concentration is shown.</p>

B - The sample result was less than 5 times blank contamination. Cross contamination is suspected.

J - The analyte was positively identified, but the concentration is an estimated value.

a - The analyte was found in the method blank.

k - The analyte was found in a field blank.

q - The analyte detected was below the Practical Quantitation Limit (PQL).

Only analytes positively detected in samples are presented in this table. For a complete list of constituents analyzed, refer to the laboratory data package.

 μ g/L - Micrograms per liter mg/L - Milligrams per liter

MCL - California Department of Public Health Maximum Contaminant Level.

DWNL - California Department of Public Health drinking water notification level.

(1) - DWNL

" - " MCL/DWNL not established.

NA - Not analyzed.

Bold - MCL or DWNL exceeded.

< # - Method detection limit concentration is shown.</p>

B - The sample result was less than 5 times blank contamination. Cross contamination is suspected.

J - The analyte was positively identified, but the concentration is an estimated value.

a - The analyte was found in the method blank.

k - The analyte was found in a field blank.

q - The analyte detected was below the Practical Quantitation Limit (PQL).

Only analytes positively detected in samples are presented in this table. For a complete list of constituents analyzed, refer to the laboratory data package.

- (1) As calcium carbonate (CaCO3).
- (2) As nitrogen (N).
- (3) DWNL
- mg/L Milligrams per liter.
- $\mu g/L$ Micrograms per liter
- MCL California Department of Public Health Maximum Contaminant Level.
- DWNL California Department of Public Health state drinking water notification level.
- "-" MCL or DWNL not available.
- Bold MCL or DWNL exceeded.
- < # Method detection limit concentration is shown.

- $B-The\ result\ is<5\ times\ the\ blank\ contamination.\ Cross\ contamination\ is\ suspected\ and\ the\ data\ is\ considered\ unusable$
- J The analyte was positively identified, but the analyte concentration is an estimated value.
- U The analyte was not detected above the MDL.
- a The analyte was found in the method blank.
- c The Matrix Spike (MS) and/or Matrix Spike Duplicate (MSD) recoveries were outside control limits.
- e a holding time violation occurred.
- f The duplicate Relative Percent Difference (RPD) was outside the control limit
- k The analyte was found in a field blank.
- \boldsymbol{q} The analyte detection was below the Practical Quantitation Limit (PQL).

3.5 Chemicals of Potential Concern

The identification of COPCs is an ongoing process that takes place annually as part of the Second Quarter sampling. The purpose of identifying COPCs is to establish a list of analytes that best represents the extent and magnitude of affected groundwater and to focus more detailed analysis on those analytes. The analytes were organized and evaluated in two groups, organic and inorganic analytes, and divided into primary and secondary COPCs. Table 3-10 presents a summary of the Site 2 COPCs. Laboratory analytical results from the Second Quarter 2010 and Third Quarter 2010 monitoring events are presented in the following two subsections. Tables 3-4 through 3-7 present a summary of validated organic and inorganic analytes detected during the Second Quarter 2010 and Third Quarter 2010 monitoring events. Data which are B qualified because of association with either laboratory or field contamination is not included in the COPC evaluation.

Table 3-10 Groundwater Chemicals of Potential Concern

Analyte	Classification
Perchlorate	Primary
Trichloroethene	Primary
1,4-Dioxane	Primary
Benzene	Secondary
Methylene Chloride	Secondary
RDX	Secondary
Notes:	
RDX - Hexahydro-1,3,	5-trinitro-1,3,5-triazine

3.5.1 Organic Analytes

Six organic analytes (1,4-dioxane, 1,2-DCA, 1,1-DCE, benzene, RDX, and TCE) were detected above a published MCL or DWNL during the Second Quarter 2010 monitoring event. Table 3-4 presents a summary of validated organic analyte concentrations reported in groundwater samples collected during the Second Quarter 2010 groundwater monitoring event.

1,4-Dioxane was reported in groundwater samples collected from five monitoring wells, TT-MW2-5, TT-MW2-9S, TT-MW2-22, TT-MW2-24, and TT-MW2-37A, during the Second Quarter 2010 monitoring event at concentrations ranging from 0.92 μ g/L to 250 μ g/L. All wells are located within or just downgradient of the former WDA. The DWNL for 1,4-dioxane is 1 μ g/L. Figure 3-5 presents a 1,4-dioxane isoconcentration map for groundwater samples collected during the Second Quarter 2010 monitoring event.

1,2-DCA was reported in groundwater samples collected from two monitoring wells, TT-MW2-22 and TT-MW2-24, located in the former WDA, during the Second Quarter 2010 monitoring event at concentrations of 1.3 µg/L and 0.74 µg/L respectively. The MCL for 1,2-DCA is 0.5 µg/L.

1,1-DCE was reported in groundwater samples collected from two monitoring wells, TT-MW2-22 and TT-MW2-24, located in the former WDA during the Second Quarter 2010 monitoring event at concentrations of $26 \mu g/L$ and $2.8 \mu g/L$ respectively. The MCL for 1,1-DCE is $6 \mu g/L$.

Benzene was reported in groundwater samples collected from nine monitoring wells during the Second Quarter 2010 monitoring event, at concentrations ranging from 0.17 μ g/L to 16 μ g/L. TT-MW2-31B, TT-MW2-33C, TT-MW2-36C, TT-MW2-40B, and TT-MW2-40C located in Area K, TT-MW2-35B located in Area L, and TT-MW2-22, TT-MW2-24, and TT-MW2-37A, located within the former WDA. The highest benzene detection, 16 μ g/L, was from monitoring well TT-MW2-40B. This well has historically had benzene detections ranging from 8 μ g/L to 26 μ g/L. The remaining benzene detections, both historic and recent, have been below the MCL of 1 μ g/L. The source of the benzene detected in TT-MW2-40B is unknown, but may be a result of difficulties encountered during drilling operations when the drill rig jaw retaining bolts sheared off and the jaws fell into the borehole.

RDX was reported in groundwater samples collected from two monitoring wells in two locations during the Second Quarter 2010 monitoring event: TT-MW2-13, located in Area K; and TT-MW2-24, located in the former WDA, at concentrations of 0.32 μ g/L and 3.2 μ g/L respectively. The DWNL for RDX is 0.3 μ g/L. These results are consistent with historic data.

TCE was reported in groundwater samples collected from four monitoring wells (TT-MW2-21, TT-MW2-22, TT-MW2-24, and TT-MW2-37A) located in the former WDA during the Second Quarter 2010 monitoring event, at concentrations of 3.4 μ g/L, 470 μ g/L, 97 μ g/L, and 2.0 μ g/L

respectively. TCE was also detected in monitoring well TT-MW2-9S, located downgradient of the former WDA, at a concentration of 0.92 μ g/L. TCE was also reported in monitoring wells TT-MW2-17S and TT-MW2-17D, located in Area K at concentrations of 0.35 μ g/L and 2.6 μ g/L respectively; and in monitoring well TT-MW2-11, located in Area M at a concentration of 11 μ g/L. The MCL for TCE is 5 μ g/L. Figure 3-6 presents a TCE isoconcentration map for groundwater samples collected during the Second Quarter 2010 monitoring event. Time-series graphs of TCE are provided in Appendix I.

Methylene chloride was not detected above the MCL during the Second or Third Quarter 2010 sampling events. Previously, methylene chloride has been detected as high as 380 μ g/L in monitoring well TT-MW2-14, located in Area K, and as high as 220 μ g/L in monitoring well TT-MW2-21, located in the former WDA. Methylene chloride has not been detected at concentrations above the MDL in monitoring well TT-MW2-14, but continues to be detected at concentrations above the MDL but below the MCL in TT-MW2-21.

Other organic analytes detected at low levels and below their respective MCLs or DWNLs during the Second Quarter 2010 groundwater monitoring event were NDMA, acetone, 2-butanone, carbon disulfide, chloromethane, chloroform, 1,1-DCA, cis-1,2-DCE, ethylbenzene, toluene, 1,1,2-trichloroethane, tetrachloroethene (PCE), and m,p-xylenes and o-xylene. None of these compounds exceeded their MCL or DWNL, and generally they are not detected consistently from monitoring event to event.

Due to the scattered nature of the locations where NDMA has been detected, the potential for cross-contamination from an outside source was investigated. The majority of NDMA detections, both historic and recent, occurred in wells sampled with the site-approved dedicated pump. Therefore, a leach test was conducted on the pump to determine if the pump was a source of the NDMA detections. A new pump with attached hoses and safety cables of the type used on the Site was obtained for leach testing. The pump was placed in a section of well casing which was filled with deionized water. The pump was then operated until water was flowing through the pump. A second section of blank well casing was filled with deionized water as a control sample. Both sections of pipe were covered and allowed to stand for three days. The water in the casing with the pump was pumped into sample bottles and the control sample was poured into sample bottles. All samples were then submitted to Babcock Laboratories Inc for analysis by EPA Method 521.

Sample results showed detections of 20 nanograms per liter (ng/L) and 10 ng/L in the primary and duplicate sample, respectively. NDMA was not detected above the method detection limit of 0.7 ng/L in the control sample. These results suggest that NDMA may be introduced into environmental samples by leaching from the dedicated sampling pumps.

As a follow up to the leach testing, the dedicated pumps from six monitoring wells that have had recent NDMA detections were removed at the conclusion of the Fourth Quarter 2009 groundwater monitoring event. The wells were allowed to equilibrate until Second Quarter 2010 at which time they were sampled for NDMA with a portable bladder pump. The data was compared to previous results obtained by purging and sampling with the dedicated pumps to determine the potential for the dedicated pumps being a possible source for the NDMA. NDMA was not detected above the MDL in four of the six wells. The remaining two wells had significantly lower detections than the previous sample results. Table 3-11 presents a summary of the Second Quarter 2010 and historical NDMA sample results for those six wells.

Several lines of evidence strongly suggest that NDMA detections at the Site are not due to environmental contamination:

- the initial NDMA detections in the second quarter 2009 were all at relatively low concentrations and were scattered across the Site rather than associated with one or more possible source areas;
- the results of the leach testing described above indicate that low levels of NDMA may be introduced into the environmental samples by leaching from the dedicated sampling pumps; and
- the NDMA sampling results summarized in Table 3-11 indicate that purging with a different type of sampling pump resulted in non-detectable NDMA in four of six wells, and much lower concentrations (which are well below the DWNL of 10 ng/L) in the two remaining wells.

Based on these lines of evidence, we conclude that the NDMA detections at the Site are not due to environmental contamination. No further sampling for NDMA will be conducted during future groundwater monitoring events.

Table 3-11 NDMA Pump Comparison Summary

Sample Location	Date Sampled	NDMA (ng/L)	Analytical Method	Pump Type

NDMA - N-Nitrosodimethylamine

ng/L - Nanograms per liter

Bold - California Department of Public Health drinking water notification level of 10 ng/L exceeded.

- < # Method detection limit concentration is shown.
- J The analyte was positively identified, but the concentration is an estimated value.
- b The surrogate spike recovery was outside control limits.
- d The Laboratory Control Sample (LCS) recovery was outside control limits.
- $\ensuremath{\mathrm{f}}$ The duplicate Relative Percent Differnce was outside the control limit
- q The analyte detection was below the Practical Quantitation Limit (PQL).

Five additional wells, TT-MW2-20S, TT-MW2-21, TT-MW2-25, TT-MW2-41A, and TT-MW2-42A, were sampled for NDMA during the Second Quarter 2010 monitoring event. Four wells, TT-MW2-20S, TT-MW2-21, TT-MW2-25, and TT-MW2-41A were sampled using the site approved dedicated sampling pump and the remaining well; TT-MW2-42A was sampled using a portable bladder pump. NDMA was detected in for wells at concentrations ranging from 1.0 ng/L to 1.8 ng/L. Table 3-12 presents a summary of the Second Quarter 2010 and historical NDMA sample results for those six wells.

Table 3-12 NDMA Detection Summary

Notes:

NDMA - N-Nitrosodimethylamine

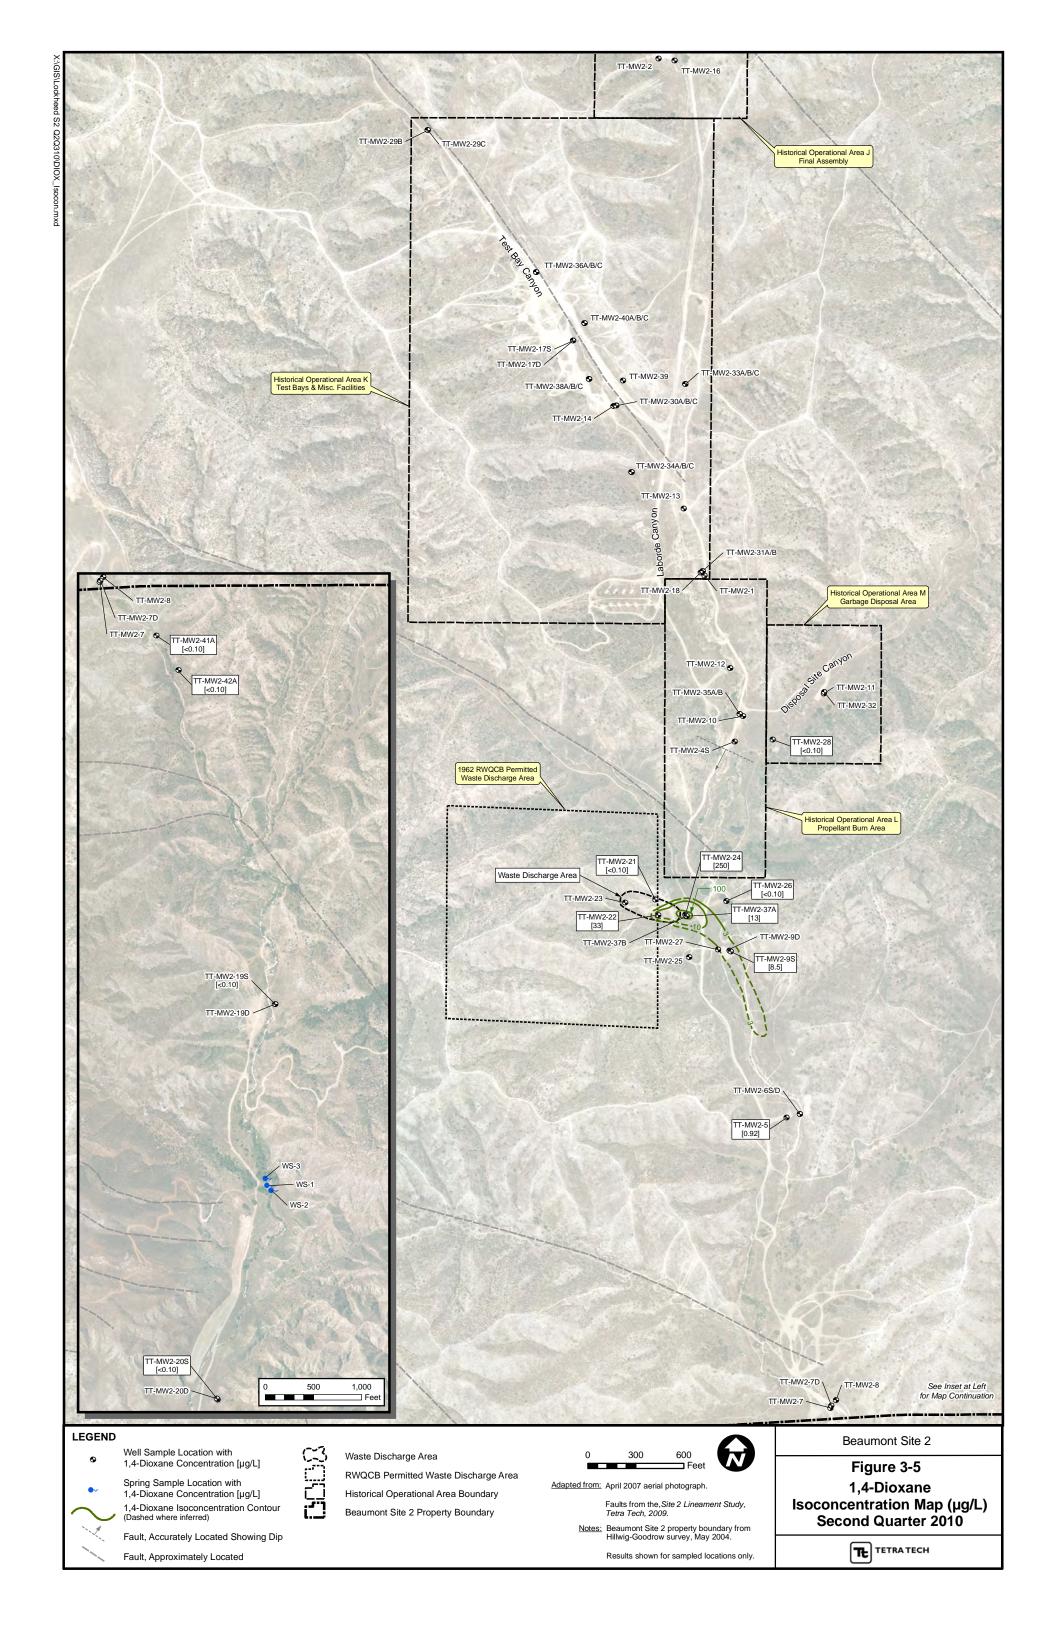

ng/L - Nanograms per liter

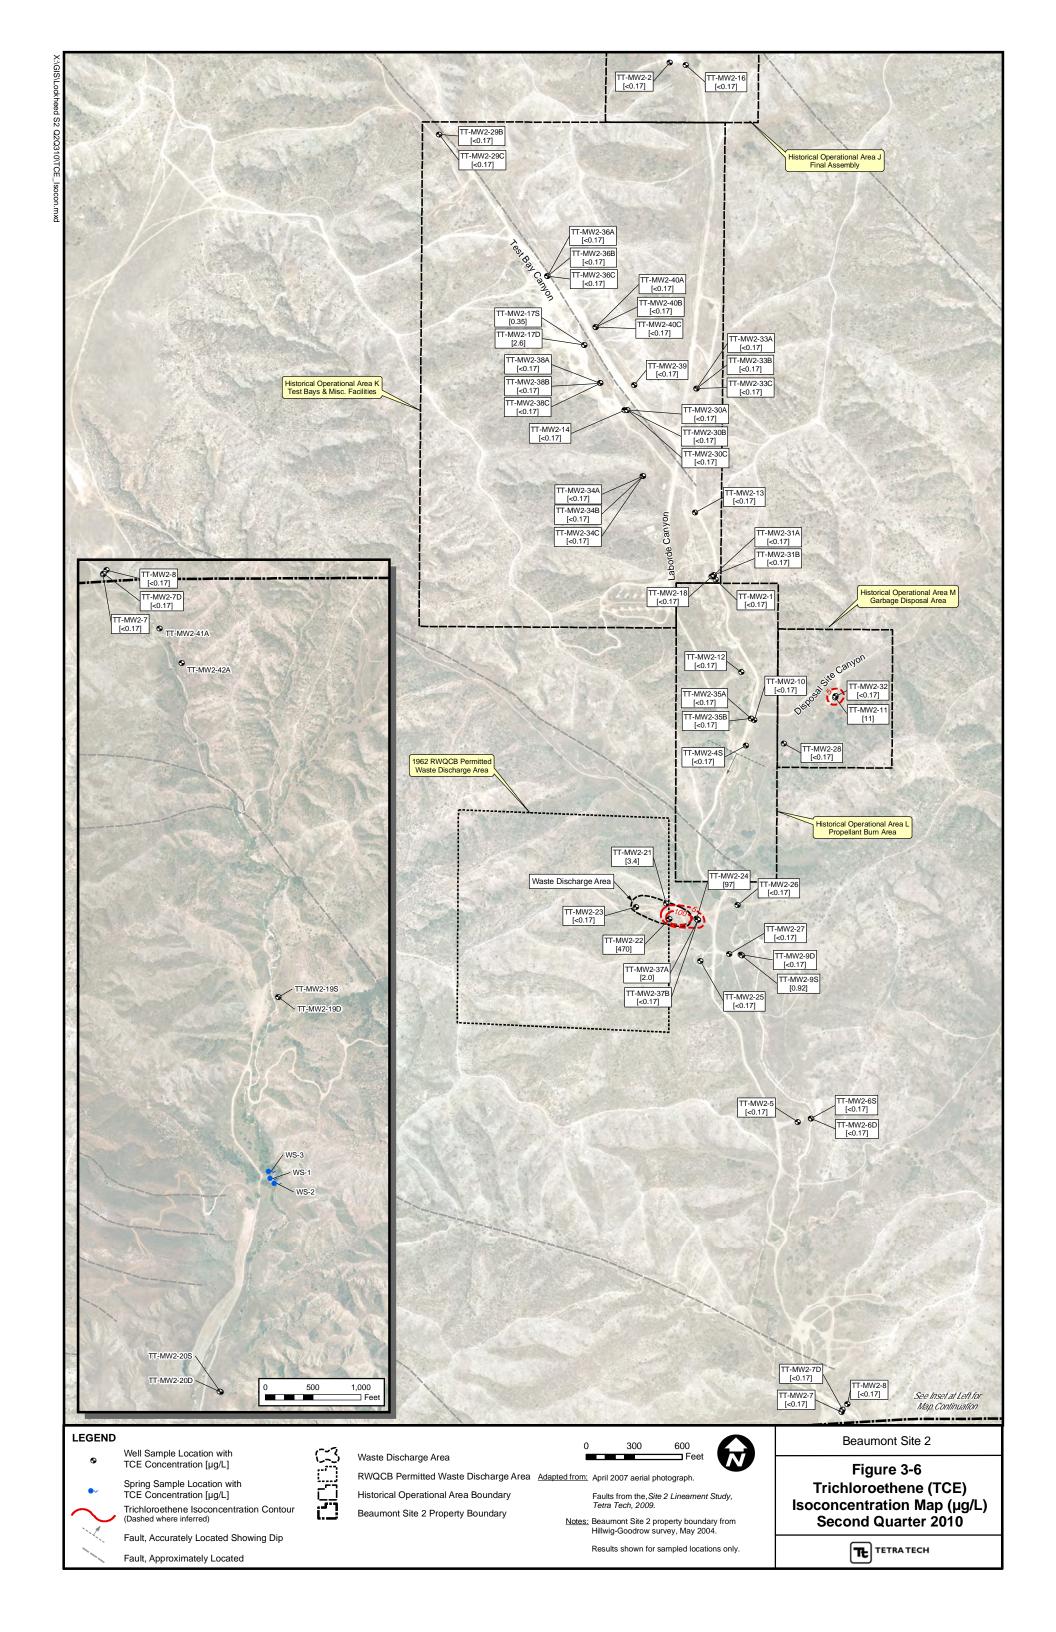

Bold - California Department of Public Health drinking water notification level of 10 ng/L exceeded.

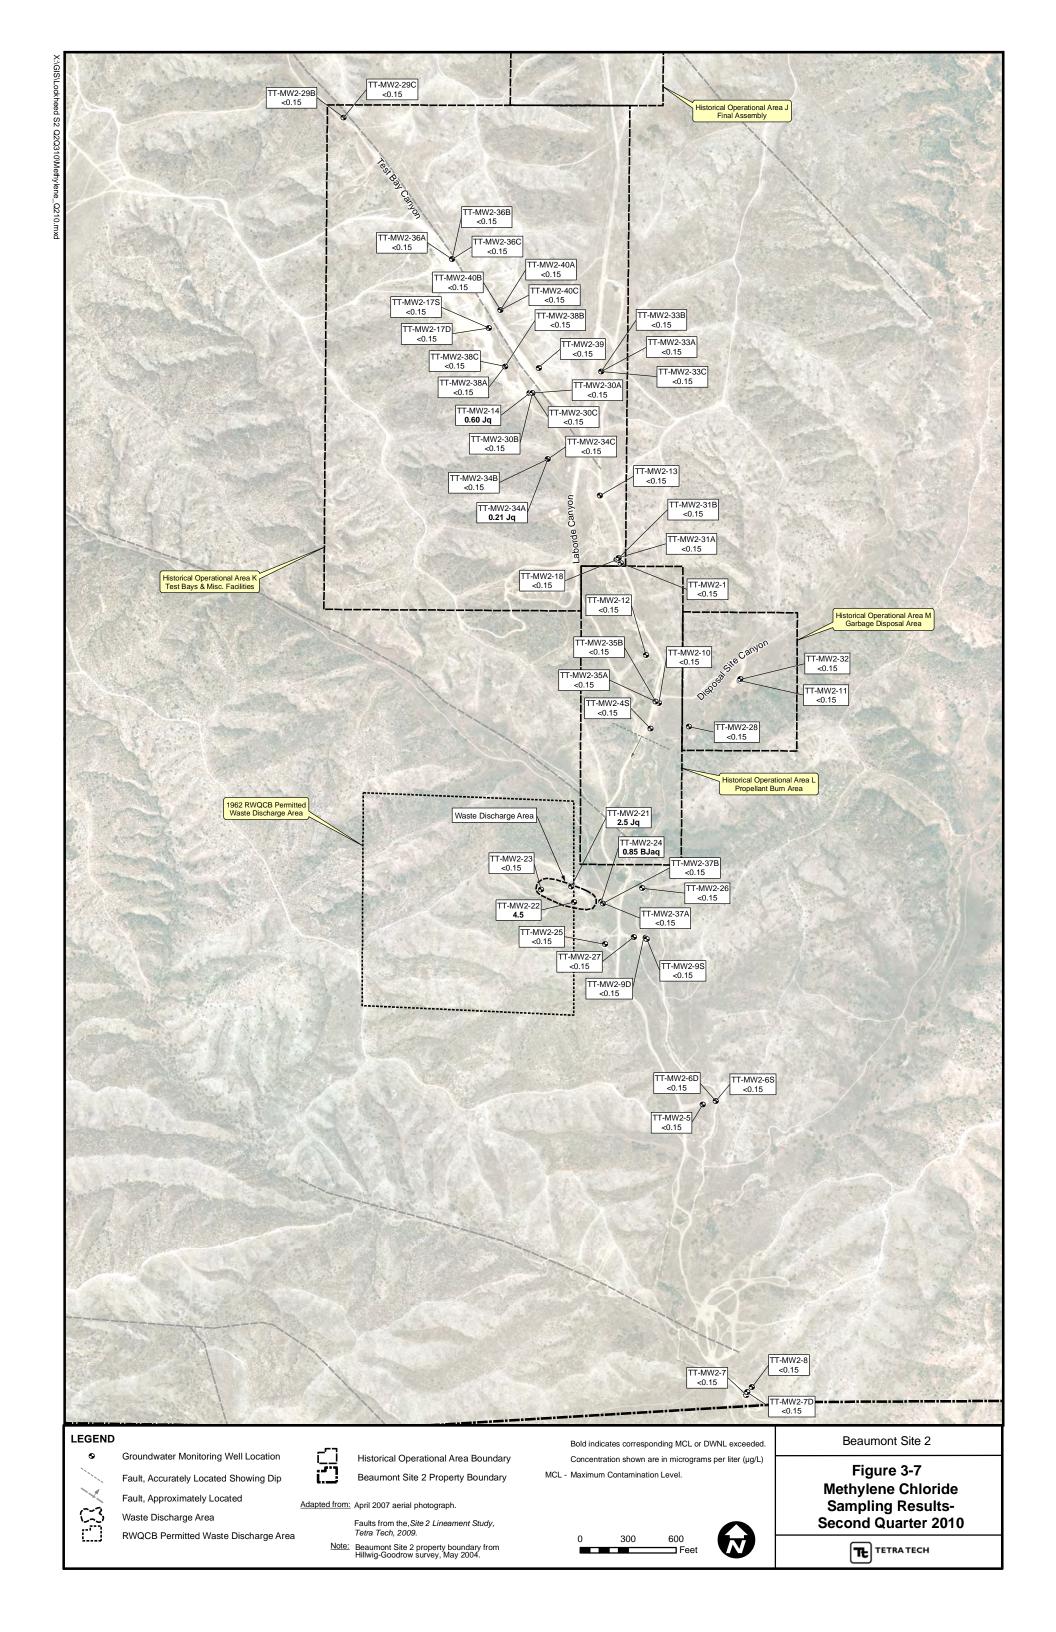

- < # Method detection limit concentration is shown.
- J The analyte was positively identified, but the concentration is an estimated value.
- U The analyte was analyzed for , but was not detected above the MDL.
- b The surrogate spike recovery was outside control limits.
- $\mbox{\bf d}$ The Laboratory Control Sample (LCS) recovery was outside control limits.
- q The analyte detection was below the Practical Quantitation Limit (PQL).

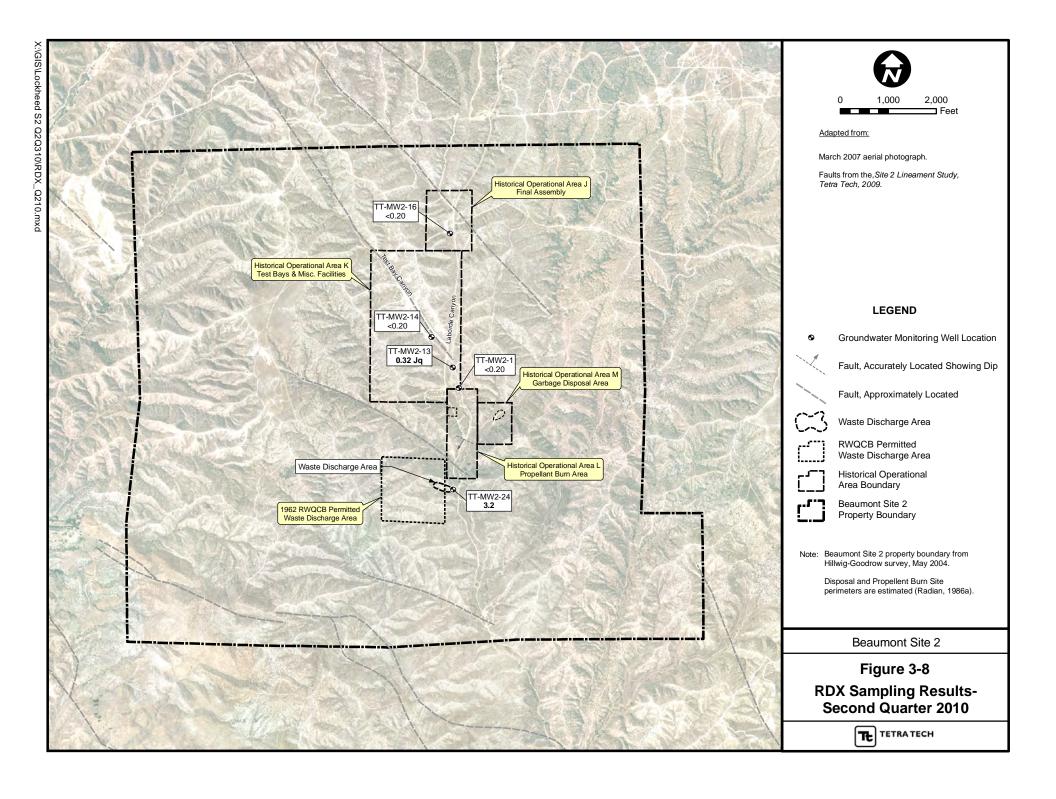

3.5.2 Organic COPCs

Based on the analysis above and the concentrations detected during previous groundwater monitoring events, TCE, and 1,4-dioxane have been identified as primary organic COPCs and benzene, methylene chloride, and RDX have been identified as secondary COPCs at the Site. Based on the available data, NDMA detections are consistent with cross-contamination from the dedicated sampling pumps, and it is proposed that further sampling for NDMA be discontinued in future groundwater monitoring events. The remaining 15 organic analytes were either detected below their respective MCL or DWNL or at relatively low concentrations. Their distribution and concentrations in groundwater will continue to be monitored and the results evaluated. Figures 3-7 and 3-8 presents sampling results for methylene chloride and RDX for groundwater samples collected during the Second Quarter 2010 monitoring event.

3.5.3 Inorganic Analytes

Seven inorganic analytes (perchlorate, total arsenic, total barium, total iron, total nickel, total vanadium, and dissolved manganese) were detected in groundwater above a published MCL or DWNL. Tables 3-5 and 3-7 present a summary of validated inorganic analyte concentrations reported in groundwater samples collected during the Second Quarter 2010 and Third Quarter 2010 groundwater monitoring events.

Perchlorate was reported in groundwater samples collected from 35 of 68 locations sampled during the Second Quarter 2010 groundwater monitoring event at concentrations up to 200,000 μ g/L; and 2 of 8 locations sampled during the Third Quarter 2010 monitoring event, at concentrations up to 4.8 μ g/L. The California MCL for perchlorate is 6 μ g/L. Figure 3-9 presents a perchlorate isoconcentration map for groundwater samples collected for the Second Quarter 2010. Time-series graphs of perchlorate are provided in Appendix I.

Total arsenic was detected in 54 of 62 unfiltered samples collected from groundwater monitoring wells during the Second Quarter 2010 groundwater monitoring event. The concentrations ranged from 0.0016 to 0.046 mg/L. Seventeen of the wells had concentrations that exceeded the 0.01 mg/L MCL for arsenic.

Generally, concentrations of arsenic in wells screened in the STF are elevated, while those screened in the QAL/wSTF are not. Groundwater in many of these same wells, including those with arsenic concentrations above the MCL, exhibit low DO and low ORP. Oxidizing conditions favor the formation of As(V) (arsenate) oxyanions, which sorb strongly to iron and aluminum oxides minerals in the aquifer, whereas reducing conditions favor the formation of As(III) (arsenite) oxyanions, which are not as strongly sorbed to iron and aluminum oxides. These sorption reactions are the dominant control on arsenic solubility and transport in the environment. Therefore, it is possible that the elevated arsenic concentrations observed in more reduced wells may be naturally occurring.

Total barium was detected in 62 of 62 unfiltered samples collected from groundwater monitoring wells during the Second Quarter 2010 groundwater monitoring event. The concentrations ranged from 0.00068 to 1.4 mg/L. One well, TT-MW2-37A, had a concentration that exceeded the 1.0 mg/L MCL for barium.

Total iron was detected in 10 of 12 unfiltered samples collected from groundwater monitoring wells during the Second Quarter 2010 groundwater monitoring event. The concentrations ranged from 22 to 2,700 μ g /L. Three of the wells had concentrations that exceeded the 300 μ g /L MCL for iron.

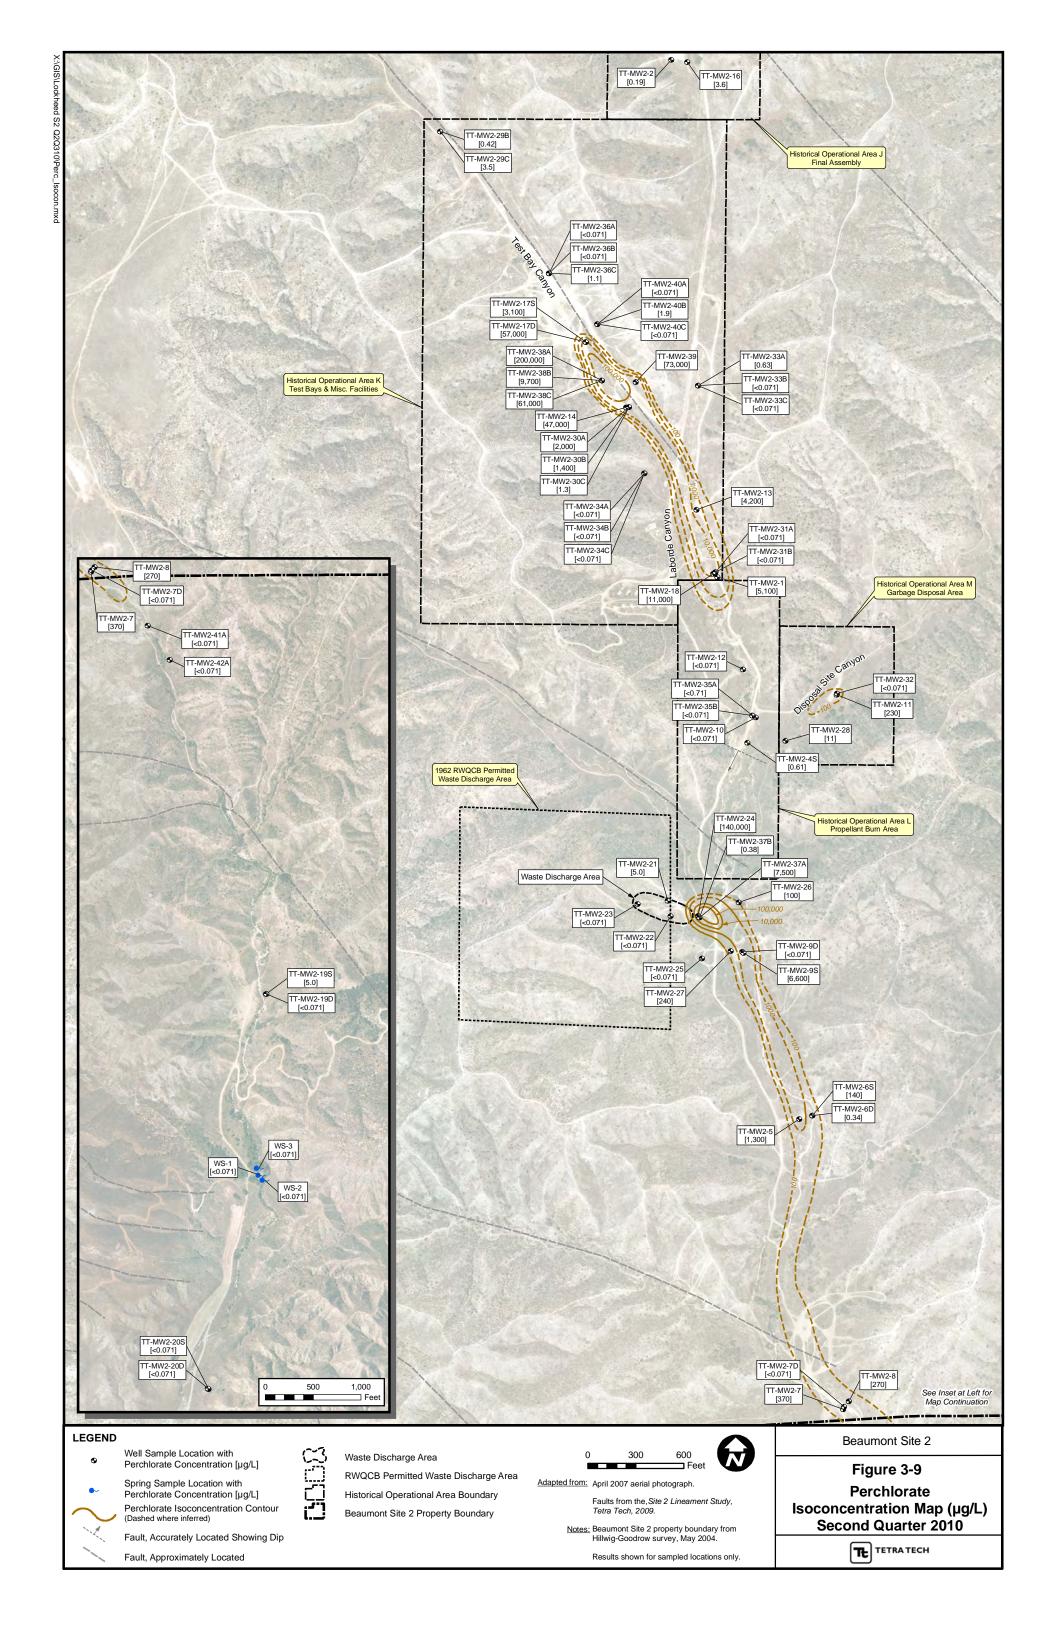

Total nickel was detected in 48 of 62 unfiltered samples collected from groundwater monitoring wells during the Second Quarter 2010 groundwater monitoring event. The concentrations ranged from 0.0015 to 0.35 mg/L. Four wells had concentrations that exceeded the 0.1 mg/L MCL for nickel.

Total vanadium was detected in 35 of 62 unfiltered samples collected from groundwater monitoring wells during the Second Quarter 2010 groundwater monitoring event. The concentrations ranged from 0.0030 to 0.15 mg/L. Four wells had concentrations that exceeded the 0.05 mg/L DWNL for vanadium.

Dissolved manganese was analyzed as part of the expanded site-wide natural attenuation study. Dissolved manganese was detected in 35 of 62 filtered samples collected from groundwater monitoring wells during the Second Quarter 2010 groundwater monitoring event. The concentrations ranged from 1.2 to 660 μ g /L. One well, TT-MW2-35A, had a concentration that exceeded the 500 μ g /L MCL for manganese.

3.5.4 Inorganic COPCs

Based on the analysis above and the concentrations detected during previous groundwater monitoring events, perchlorate is the only inorganic primary COPC identified at the Site. No secondary COPCs were identified. Metals will be evaluated as part of the upcoming human health and ecological risk assessments; any metal COPCs will be identified based on the results of those studies.

3.6 Private Production Wells and Springs

Four offsite private production wells and three offsite springs were scheduled to be sampled for perchlorate by Method 332.0 during the Second Quarter 2010 sampling event. One production well could not be sampled because the pump was not in operation, and one spring was not sampled because it was dry. The remaining three production wells and two springs were sampled on 5 May 2010. Perchlorate was not detected in any samples during the Second Quarter 2010 sampling event.

3.7 Surface Water Sampling Results

Surface water samples were collected for perchlorate at three locations, WS-1, WS-2 and WS-3, from a spring on the former Wolfskill property during the Second Quarter 2010 and at two locations, WS-1 and WS-2, during Third Quarter 2010 (Figure 2-4). Perchlorate was not detected in any samples during the Second Quarter 2010 and Third Quarter 2010 sampling events.

3.8 Monitored Natural Attenuation Sampling

Eleven monitoring wells, six associated with the groundwater perchlorate plume originating from the former Test Bay Area (TT-MW2-36A, TT-MW2-17D, TT-MW2-14, TT-MW2-1, TT-MW2-12 and TT-MW2-10), and five associated with the groundwater perchlorate plume originating from the former WDA (TT-MW2-23, TT-MW2-24, TT-MW2-9S, TT-MW2-5, and TT-MW2-7) were sampled and analyzed for monitored natural attenuation parameters (MNA) during the Second Quarter 2010 monitoring event. Samples for laboratory analysis were analyzed for total organic carbon (TOC), dissolved organic carbon (DOC), total iron, sulfate, methane, hydrogen, and volatile fatty acids (VFAs). Due to the short laboratory holding times associated with ferrous iron and sulfide, ferrous iron and sulfide were analyzed in the field just prior to sampling using a field instrument. Additionally, DO and ORP were monitored with field instruments during purging and sampling. Figure 3-10 presents monitoring well locations sampled for MNA during the Second Quarter 2010 monitoring event. Table 3-13 presents a summary of detected analytes and field measurements.

As part of a site-wide natural attenuation study, all monitored site wells were sampled for alkalinity, chlorate, chloride, DOC, methane, ethane, ethene, nitrate, nitrite, sulfate, and dissolved manganese during the Second Quarter 2010 sampling event. The site-wide data will be used to help determine which areas of the site may be conducive to natural biodegradation of perchlorate, chlorinated solvents, and 1,4-dioxane and will help guide additional work planned for future monitoring events. The results of the MNA parameter sampling will be discussed in the upcoming Contaminant Attenuation Conceptual Site Model Technical Memorandum.

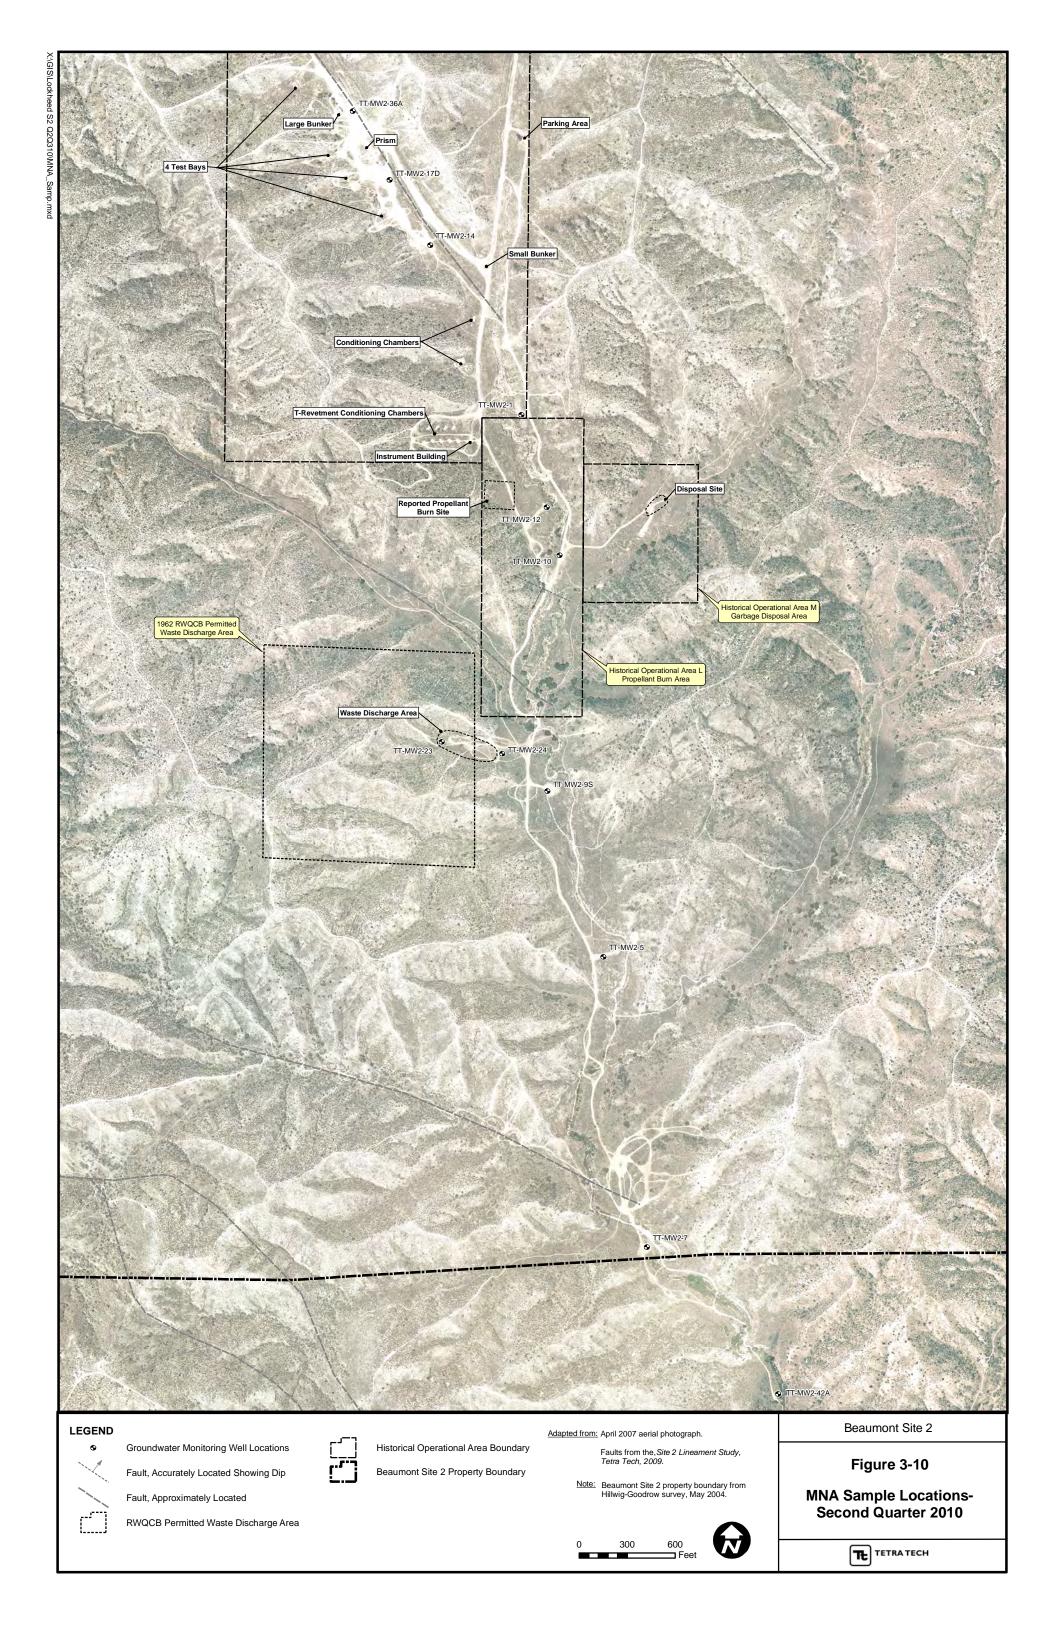

Table 3-13 Summary of Validated Detected Natural Attenuation Analytes and Field Measurements – Second Quarter 2010

			Field	Parameters			Analytes															
Sample Location	Sample Date	DO - mg/L	ORP - mVs	Sulfide - mg/L	Ferrous Iron - mg/L	Perchlorate - ug/L	Acetic Acid - mg/L	Butyric Acid - mg/L	Hexanoic Acid - mg/L	i-Hexanoic Acid - mg/L	i-Pentanoic Acid - mg/L	Lactic Acid and HIBA - mg/L	Pentanoic Acid - mg/L	Propionic Acid - mg/L	Pyruvic Acid - mg/L	Dissolved Organic Carbon - mg/L	Total Organic Carbon - mg/L	Hydrogen - nM	Methane - ug/L	Nitrate (as N) - mg/L	Sulfate - mg/L	Iron - mg/L

Notes: Only analytes positively detected are presented in this table. For a complete list, refer to the laboratory data package.

mg/L - milligrams per liter

 $\mu g/L$ - micrograms per liter.

nM - nanomoles

mV - millivolt

MCL - California Department of Public Health Maximum Contaminant Level.

DWNL - California Department of Public Health state drinking water notification level.

"-" - Not available.

<# - Analyte not detected, method detection limit concentration is shown.

Bold - MCL or DWNL exceeded.

- B The sample result was less than 5 times blank contamination. Cross contamination is suspected.
- J The analyte was positively identified, but the concentration is an estimated value.
- a The analyte was found in the method blank.
- c The Matrix Spike (MS) and/or Matrix Spike Duplicate (MSD) recoveries were outside control limits.
- f The duplicate Relative Percent Difference (RPD) was outside the control limit.
- k The analyte was found in a field blank.
- q -The analyte detected was below the Practical Quantitation Limit (PQL).

3.9 Temporal Trends in Groundwater Chemical Concentrations

All groundwater and surface water monitoring locations sampled and tested in 2010 were included in the trend analyses. Samples were collected from 64 monitoring wells and 8 fixed surface water locations. Temporal trend analyses were performed on the Site COPCs perchlorate, TCE, methylene chloride, 1,4-dioxane, and RDX. The temporal trend analyses were performed using data from September 2004 through September 2010. Statistical trend analyses were conducted for the entire period of record to evaluate the long-term trends at the Site, and to assess the variability observed in the data since many locations fluctuate considerably from quarter to quarter.

Time trend analysis was conducted using the Monitoring and Remediation Optimization System (MAROS) developed by the Air Force Center for Environmental Excellence (AFCEE, 2006). MAROS is a statistical database application developed to assist with groundwater quality data trend analysis and long-term monitoring optimization at contaminated groundwater sites. The software performs parametric and nonparametric trend analyses to evaluate temporal and spatial contaminant trends using Mann-Kendall and linear regression methods. Brief descriptions of the methods follow:

- MannKendall Analysis This statistical procedure was used to evaluate the data for trends. It is a non-parametric statistical procedure that is well suited for analyzing trends in data over time that do not require assumptions as to the statistical distribution of the data and can be used with irregular sampling intervals and missing data. The Mann-Kendall test for trends is suitable for analyzing data that follows a normal or non-normal distribution pattern. The Mann-Kendall test has no distributional assumptions and allows for irregularly spaced measurement periods. The advantage with this approach involves cases where outliers in the data would produce biased estimates of the least squares estimated slope.
- Linear Regression Analysis This statistical procedure was used to calculate the magnitude of the trends. A parametric statistical procedure is typically used for analyzing trends in data over time and requires a normal statistical distribution of the data.

There are statistical concentration trend types derived from Mann-Kendall analysis: 1) decreasing, 2) increasing 3) no trend [displaying two sets of conditions], 4) probably decreasing, 5) probably increasing, 6) stable, 7) non-detect (all sample results are below the detection limit), and 8) insufficient data (less than four quarters of data). These statistical concentration trend types are determined by the following conditions summarized in Table 3-14.

Table 3-14 Mann-Kendall Concentration Trend Matrix

Mann-Kendall Statistic (S)	Confidence in Trend	Concentration Trend				
S > 0	> 95%	Increasing				
S > 0	90 - 95%	Probably Increasing				
S > 0	< 90%	No Trend				
S ≤ 0	< 90% and COV ≥ 1	No Trend				
$S \leq 0$	< 90% and COV < 1	Stable				
S < 0	90 - 95%	Probably Decreasing				
S < 0	> 95%	Decreasing				
NA	NA	Non-detect				
Notes:						
>-	Greater than.					
<-	Less than.					
≤-	Less than or equal to.					
COV -	Coefficient of Variation.					
S -	Mann-Kendall statistic					
NA -	Not applicable to non-detect trend.					

The Mann-Kendall statistic (S) measures the trend in the data. Positive values indicate an increase in constituent concentrations over time, whereas negative values indicate a decrease in constituent concentrations over time. The strength of the trend is proportional to the magnitude of the Mann-Kendall Statistic (i.e., large magnitudes indicate a strong trend).

The Coefficient of Variation (COV) is a statistical measure of how the individual data points vary about the mean value. Values less than or near 1.00 indicate that the data form a relatively close group about the mean value. Values larger than 1.00 indicate that the data show a greater degree of scatter about the mean.

The "Confidence in Trend" is the statistical confidence that the constituent concentration is increasing (S>0) or decreasing (S<0).

The Site COPCs were analyzed for temporal trends at up to 64 monitoring wells and eight surface water or spring sample locations. If there is insufficient data (less than four sampling events) then not applicable (NA) would be applied to the results.

Any one location may have a different trend for each of the five analytes evaluated. For the monitoring well locations 279 trends were evaluated. Of the 279 trends evaluated, three had insufficient data, 59 had no trend, 176 were non-detect, ten had a decreasing trend, four had a probably decreasing trend, 14 had a stable trend, one had a probably increasing trend, and 12 had a increasing trend. A summary of the Mann-Kendall trend analysis is presented in Table 3-15.

Table 3-15 Summary of Mann-Kendall Trend Analysis of COPCs for 2010 Sampled Monitoring Wells

Analyte	Locations Tested	Insufficient Data	No Trend	Non Detect	Decreasing Trend	Probably Decreasing Trend	Stable Trend	Probably Increasing Trend	Increasing Trend
Trichloroethene	59	0	5	50	0	0	0	0	4
Methylene Chloride	59	0	17	32	4	3	2	0	1
Perchlorate	64	2	31	7	5	1	10	1	7
1,4-Dioxane	62	0	6	55	0	0	1	0	0
RDX	35	1	0	32	1	0	1	0	0
Total Analysis	279	3	59	176	10	4	14	1	12

COPC - Chemicals of Potential Concern.

The 13 probably increasing or increasing trends were detected in 11 groundwater monitoring locations. The portion of the Site where they are located, the location identification, and the COPC that has the increasing or probably increasing trend are listed below:

Four wells located in Area K:

• TT-MW2-1: perchlorate,

• TT-MW2-14: perchlorate,

• TT-MW2-17S: TCE, and

• TT-MW2-29C: perchlorate.

One well located in Area M:

• TT-MW2-11: TCE.

Three wells located in the former WDA:

- TT-MW2-21: perchlorate, TCE, and methylene chloride,
- TT-MW2-22: TCE, and
- TT-MW2-37A: perchlorate.

Two wells located just downgradient and crossgradient, respectively, of the former WDA:

- TT-MW2-9S: perchlorate, and
- TT-MW2-26: perchlorate.

One well located on the former Wolfskill property:

• TT-MW2-19S: perchlorate,

Table 3-16 provides a summary of the magnitude of the trend changes (ug/L/yr) and the percent change with respect to the mean experienced at the Site through Third Quarter 2010. These trends were generated using the MAROS software. Figures 3-11 through 3-15 present a spatial representation of the results of the trend analysis for monitoring well locations.

Table 3-16 Magnitude of Trends Detected for COPC for 2010 Sampled Monitoring Wells

		y Decreasing Trend		Probably Incre	Increasing Trend							
	Number	Magnitude	- Number	Magnitude	Number	Location	Magi	nitude	Number	Location	Magnitude	
Analyte		(ug/L/yr)		(ug/L/yr)			(ug/L/yr)	(%/yr)			(ug/L/yr)	(%/yr)
Trichloroethene	0	NA	0	NA	0	NA	NA		4	TT-MW2-11	0.59	8.4
										TT-MW2-17S	0.13	10.8
										TT-MW2-21	0.76	58.4
										TT-MW2-22	118.63	47.5
Methylene Chloride	4	0.27 to 204.40	3	0.34 to 0.55	0	NA	NA		1	TT-MW2-21	1.08	40.2
Perchlorate	6	0.09 to 4,507.75	1	182.32	1	TT-MW2-37A	2,628.00	109.50	7	TT-MW2-1	444.57	7.7
										TT-MW2-9S	51.1	51.1
										TT-MW2-14	1,177.13	2.7
										TT-MW2-19S	1.41	40.2
										TT-MW2-21	0.79	49.3
										TT-MW2-26 TT-MW2-	26.92	45.6
										29C	1	100.4
1,4-Dioxane	0	NA	0	NA	0		ļ	NA	0	NA	NA	NA
RDX	1	0.23	0	NA	0			NA	0	NA	NA	NA

ug/L/yr - Micrograms per liter per year.

NA - Not applicable.

%/yr - Percent change per year with respect to the sample mean.

COPC - Chemicals of Potential Concern.

For the eight surface water locations, 18 trends were evaluated. Of the 18 trends that were evaluated: 6 had insufficient data, 0 had no trend, 10 were non-detect, 1 had a decreasing trend, 0 had a probably decreasing trend, 1 had a stable trend, 0 had a probably increasing trend, and 0 had an increasing trend. A summary of the Mann-Kendall trend analysis is presented in Table 3-17.

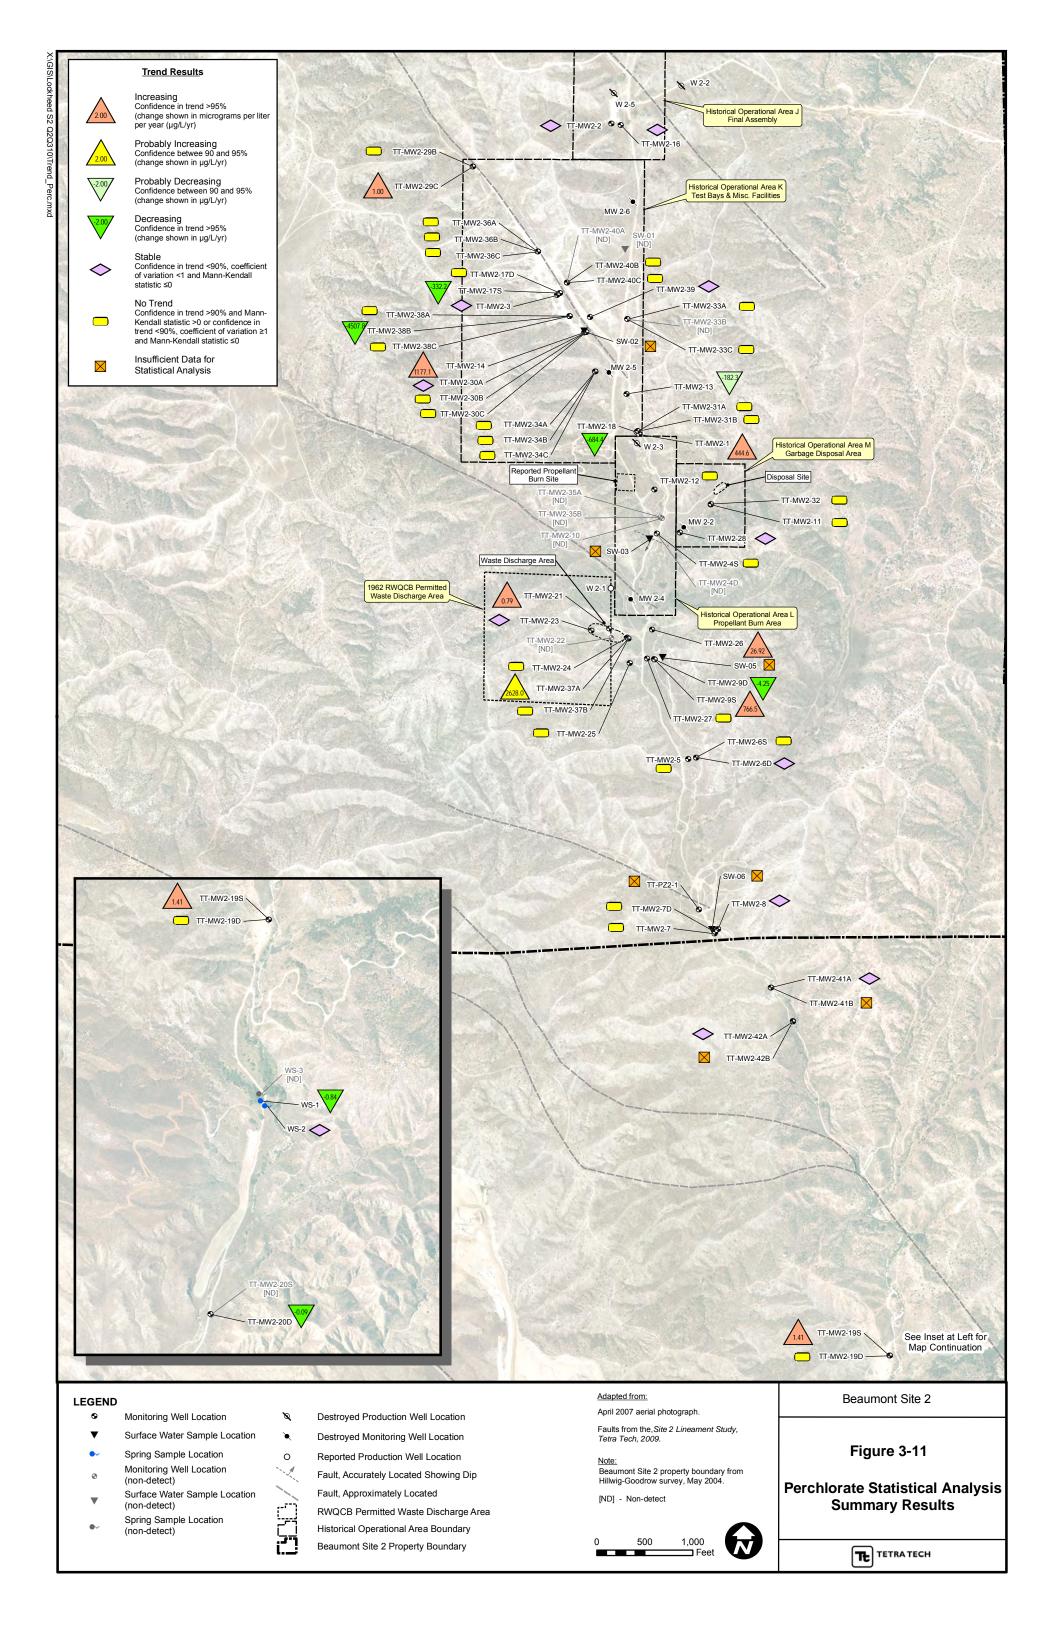

Table 3-17 Summary of Mann-Kendall Trend Analysis of COPCs for 2010 Sampled Surface Water and Spring Locations

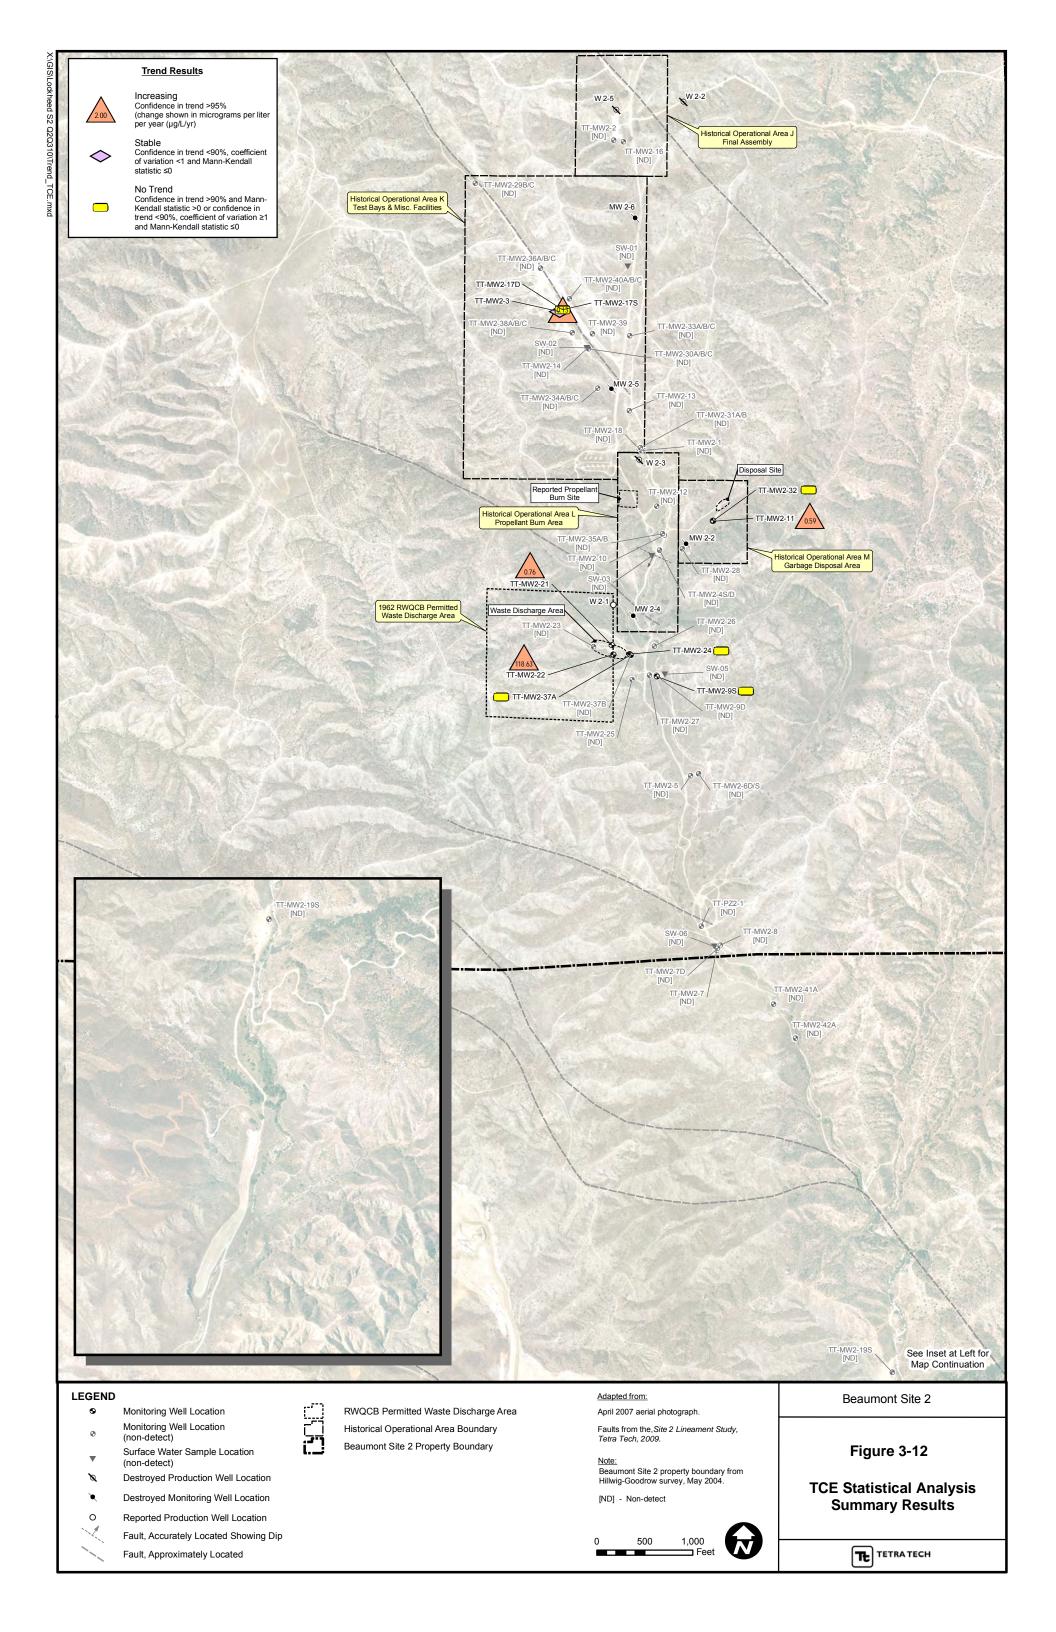

Analyte	Locations Tested	Insufficient Data	No Trend	Non Detect	Decreasing Trend	Probably Decreasing Trend	Stable Trend	Probably Increasing Trend	Increasing Trend
Trichloroethene	5	0	0	5	0	0	0	0	0
Methylene Chloride	5	1	0	4	0	0	0	0	0
Perchlorate	8	5	0	1	1	0	1	0	0
1,4-Dioxane	0	0	0	0	0	0	0	0	0
RDX	0	0	0	0	0	0	0	0	0
Total Analysis	18	6	0	10	1	0	1	0	0

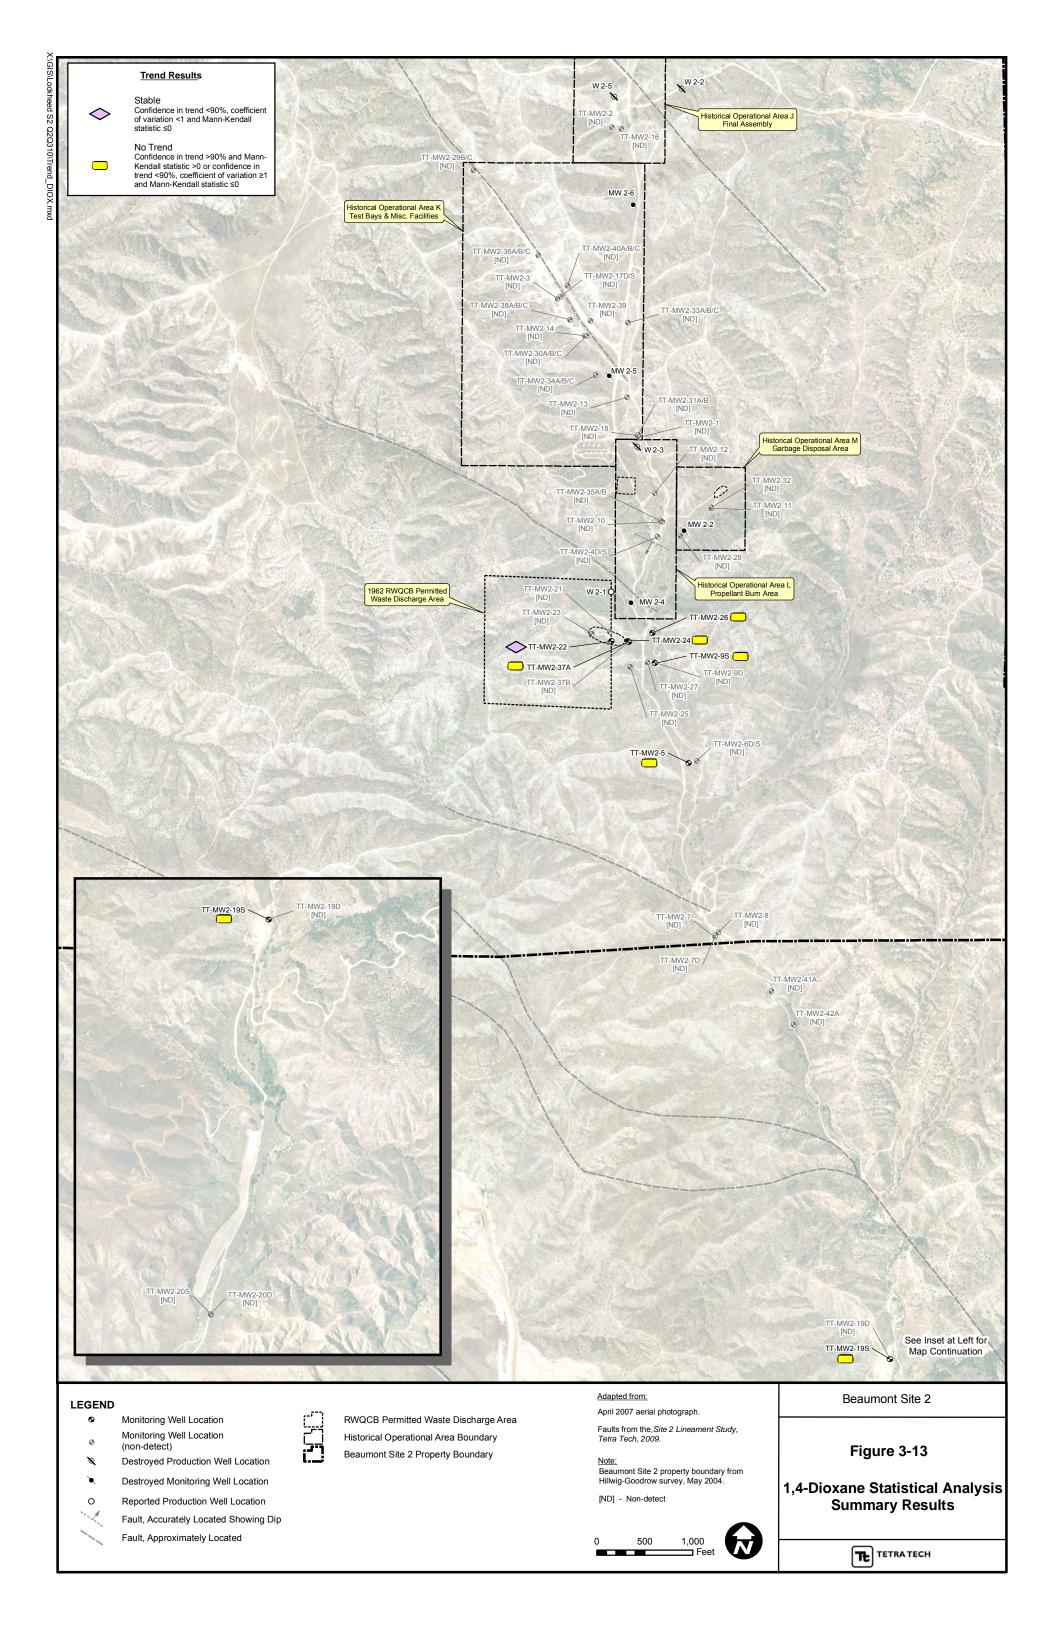

Notes:

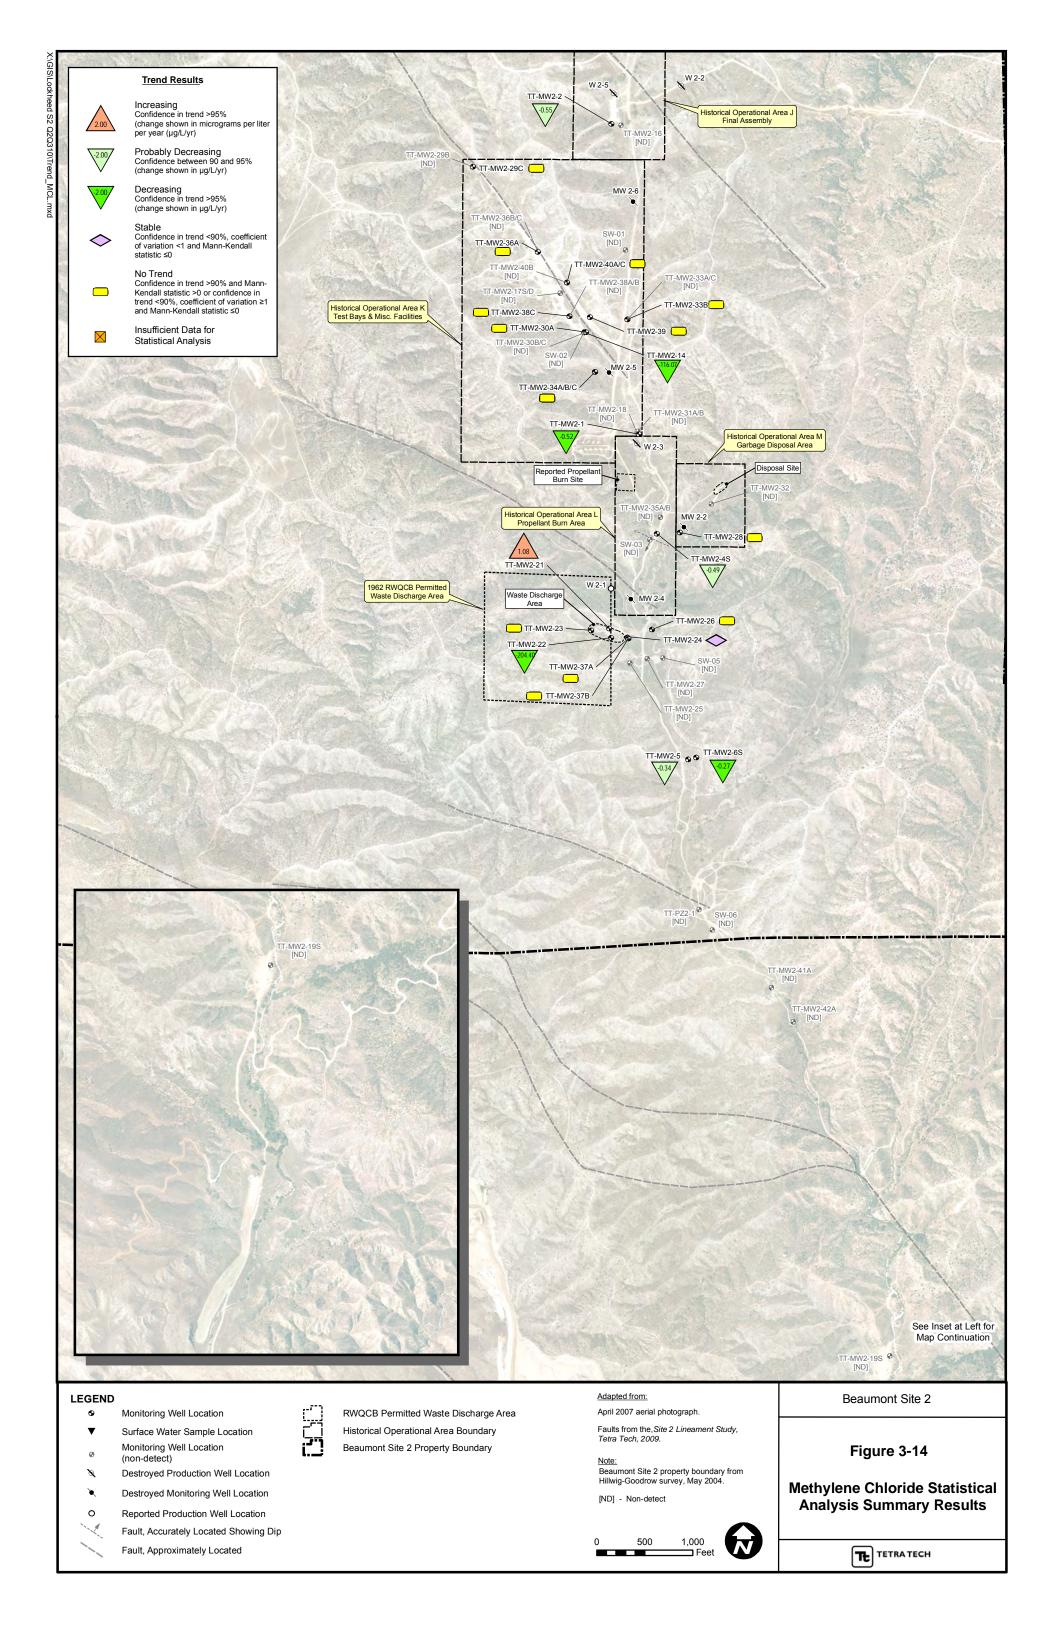

COPC - Chemicals of Potential Concern.

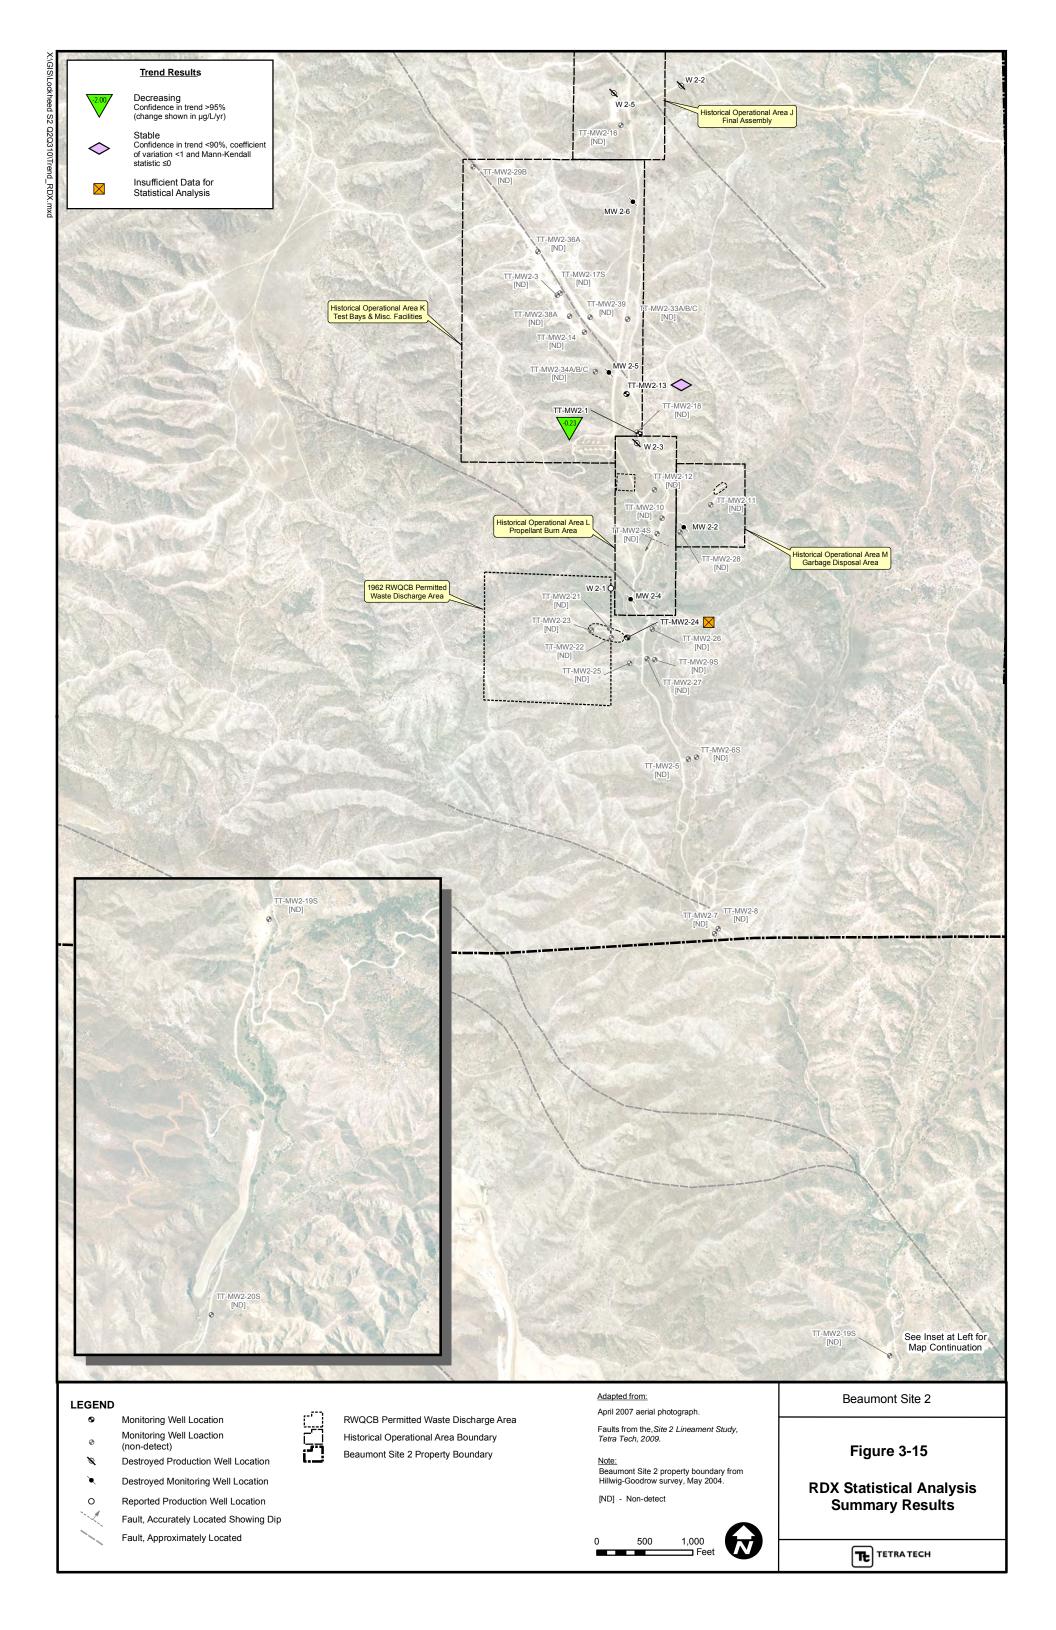

Surface water location WS-1 had a decreasing trend for perchlorate. The remaining surface water locations had either stable or ND trends, or had insufficient data for Mann-Kendall trend analysis. Appendix J presents a summary of the results of the Mann-Kendall and linear regression analyses and a comparison of the historical TCE and perchlorate trend analyses.

3.10 Habitat Conservation

Consistent with the U.S. Fish and Wildlife Service approved HCP (USFWS, 2005) and subsequent clarifications (LMC, 2006a, 2006b and 2006c) of the HCP describing activities for environmental remediation at the Site, field activities were performed under the supervision of a USFWS approved biologist. As a result, no impact to SKR occurred during the performance of the field activities related to the Second Quarter 2010 and Third Quarter 2010 monitoring events.

Section 4 Summary and Conclusions

This section summarizes the results of the Second Quarter 2010 and Third Quarter 2010 groundwater monitoring events. During the Second Quarter 2010 monitoring event 67 monitoring well locations and two piezometers were measured for groundwater levels and 62 monitoring wells, five private production wells or springs and three surface water locations were sampled for groundwater quality. Two monitoring wells, TT-MW2-29A and TT-MW2-43, were dry during the Second Quarter 2010 monitoring event. During the Third Quarter 2010 monitoring event 67 monitoring well locations and two piezometers were measured for groundwater levels and six monitoring wells, and two surface water locations were sampled for groundwater quality. Two monitoring wells, TT-MW2-29A and TT-MW2-43, and one surface water location, WS-3, were found to be dry during the Third Quarter 2010 monitoring event.

4.1 Groundwater Elevation and Flow

During the Second Quarter 2010 and Third Quarter 2010 monitoring events, groundwater elevations at the Site ranged from about 2075 feet msl in the northern portion of the Site, to about 1819 feet msl in the southern portion of the Site. Depth to groundwater ranged from about 122 feet bgs to about 17 feet bgs.

Based on the measured groundwater elevations, the current CSM, and the southward sloping topography at the Site, groundwater flow in the QAL/wSTF and STF screened wells appears to be southerly and generally follows the topography of Laborde Canyon. The overall groundwater elevation at the Site has decreased four to six feet since Fourth Quarter 2005 with the greatest decrease over time seen in monitoring well TT-MW2-1 (5.91 feet). Limited seasonal fluctuations can be seen to varying degrees following periods of precipitation.

Generally, the seasonal fluctuations in the northern portion of the Site are less pronounced and have a three to four month delay before a change in groundwater elevation is noticeable. The wells in Test Bay Canyon, however, appear to respond faster and have a greater change in elevation than the wells in the main portion of Laborde canyon.

In the southern portion of the Site between the former WDA and the southern Site boundary the seasonal fluctuations tend to be more pronounced with a shorter response time. This is most noticeable in the shallow wells located near the southern property boundary and in the riparian area just south of the property boundary.

On the former Wolfskill property the groundwater elevation has remained relatively stable with noticeable seasonal fluctuations.

Although the data are limited in many of the newer wells, the overall long-term decreasing trend in groundwater elevation appears to correspond to the long-term precipitation pattern.

4.1.1 Groundwater Gradients

Horizontal groundwater gradients across the Site are relatively constant. The horizontal groundwater gradients calculated between TT-MW2-16 and TT-MW2-6S from the Second Quarter 2010 and Third Quarter 2010 groundwater monitoring events for the QAL/wSTF screened wells averaged 0.030 ft/ft. The horizontal groundwater gradients calculated between TT-MW2-2 and TT-MW2-6D for the Second Quarter 2010 and Third Quarter 2010 groundwater monitoring events for the deeper STF screened wells averaged 0.029 ft/ft.

Generally the vertical gradients are downward on site and upward from the Site boundary south. The vertical gradients range from negative 0.29 to positive 0.19. A summary of calculated horizontal and vertical groundwater gradients is presented in Table 3-3 and in Appendix E.

4.2 Water Quality Monitoring

Both groundwater and surface water are collected and sampled as part of the GMP. The GMP has a quarterly/semiannual/annual frequency. The annual events are larger major monitoring events and the quarterly and semiannual events are smaller minor events. All new wells are sampled quarterly for one year. The semiannual wells are sampled second and fourth quarter of each year, and the annual wells are sampled second quarter of each year.

Groundwater samples collected during the Second Quarter 2010 and Third Quarter 2010 monitoring events were analyzed for perchlorate. Select locations were analyzed for VOCs, natural attenuation parameters, general minerals, 1,4-dioxane, and NDMA. Based on the historical operations at the Site and groundwater monitoring results, perchlorate, TCE, and 1,4-dioxane were identified as a primary COPCs. Benzene, methylene chloride and RDX were identified as

secondary COPCs. NDMA appears to be related to cross-contamination from the dedicated sampling pumps. Sampling for NDMA will be discontinued in future monitoring events.

4.2.1 Private Production Wells and Springs

Samples from select offsite private production wells and springs were collected as part of the Second Quarter 2010 monitoring event. Wells and springs were selected that are in close proximity to the Site boundary to monitor for potential impact to offsite water supplies from groundwater leaving the Site. No COPCs were detected in the private production wells or springs that were sampled. The private production wells will continue to be monitored annually during the second quarter sampling event.

4.2.2 Surface Water

Surface water samples are collected from seven surface water sample locations within the Laborde Canyon creek bed and three spring locations at the Site located on the former Wolfskill property. Water is generally present in the Laborde Canyon creek bed only during periods of heavy, prolonged precipitation.

During the Second Quarter 2010 sampling event, surface water samples were collected from the three spring locations located on the former Wolfskill property. The samples were analyzed for perchlorate. The remaining seven surface water locations in Laborde Canyon were dry at the time of sampling.

During the Third Quarter 2010 sampling event, surface water samples were collected from two of the three spring locations located on the former Wolfskill property. The samples were analyzed for perchlorate. The remaining spring location and the seven surface water locations in Laborde Canyon were dry at the time of sampling.

Perchlorate was not detected in surface water samples collected during the Second Quarter 2010 or Third Quarter 2010 monitoring events.

4.2.3 Groundwater

Area J – Final Assembly Area

Site COPCs have not been detected above their respective MCLs or DWNLs in Area J. Perchlorate was detected in monitoring TT-MW2-16 at a concentration of 3.6 μ g/L during the Second Quarter of 2010, and has previously been detected at concentrations up to 4.94 μ g/L. A source of perchlorate in Area J has not been identified.

<u>Area K – Test Bays and Miscellaneous Facilities</u>

Perchlorate, TCE, methylene chloride, and RDX have been detected in Area K. Previously, perchlorate was detected as high as 190,000 μ g/L in Area K. During Second Quarter 2010 perchlorate was detected at concentrations ranging from below the MDL to 200,000 μ g/L. Area K has been identified as a source of perchlorate in groundwater.

TCE has been detected consistently in TT-MW2-17D at concentrations ranging from $0.46~\mu g/L$ to $1.2~\mu g/L$. TCE has not been detected in other wells located in Area K. The source of the TCE is unknown.

Methylene chloride has been detected at concentrations ranging from 380 μ g/L in Fourth Quarter 2006 to 0.60 μ g/L in Second Quarter 2010 in monitoring well TT-MW2-14. Methylene chloride has not been detected consistently in other monitoring wells located in Area K. The source of the methylene chloride is unknown.

Previously, RDX has been detected in two monitoring wells, TT-MW2-1 and TT-MW2-13, at concentrations up to 1.6 μg/L in Area K. Additional sampling has been conducted for RDX in select monitoring wells located upgradient, downgradient, and in wells screened in deeper intervals in comparison to TT-MW2-1 and TT-MW2-13 and it has not been detected above the MDL. RDX continues to be detected in TT-MW2-13 but has not been detected in TT-MW2-1 since October 2007. The source of the RDX has been investigated (Tetra Tech, 2010B; 2010e) but remains unknown.

Area L – Propellant Burn Area

Perchlorate is the only Site COPC to be detected in Area L. Area L is located downgradient of operational areas K. Previously, perchlorate was detected at concentrations up to 9.98 µg/L. During Second Quarter 2010, perchlorate was detected only in monitoring well TT-MW2-4S at a

concentration of 0.61 μ g/L. There are currently no indications that a source of perchlorate is present in Area L; the perchlorate detected in Area L groundwater appears to have originated in Area K.

<u>Area M - Garbage Disposal Area</u>

Perchlorate and TCE have been detected in Area M. Previously, perchlorate was detected at concentrations up to 469 μ g/L in well TT-MW2-11. During Second Quarter 2010, perchlorate was detected at concentrations ranging from below the MDL to 230 μ g/L. Area M has been identified as a source of perchlorate in groundwater.

TCE has been consistently detected in groundwater samples collected from monitoring well TT-MW2-11 at concentrations up to 9.2 μ g/L. During Second Quarter 2010, TCE was detected at a concentration of 11 μ g/L. TCE has not been detected in other wells in Area M.

Waste Discharge Area (WDA)

Perchlorate, TCE, methylene chloride, 1,4-dioxane, and RDX have been detected in the former WDA. The former WDA is located downgradient of operational areas J, K, L, and M. Previously, perchlorate was detected as high as 190,000 μg/L. Perchlorate in the groundwater was detected at concentrations ranging from below the MDL to 140,000 μg/L during Second Quarter 2010. The former WDA has been identified as a source of perchlorate in groundwater.

Previously, TCE was detected at concentrations as high as 460 μ g/L in monitoring wells located in the former WDA. During Second Quarter 2010, TCE was detected in monitoring wells TT-MW2-21, TT-MW2-22, TT-MW2-24, and TT-MW2-37A at concentrations of 3.4 μ g/L, 470 μ g/L, 97 μ g/L, and 2.0 μ g/L, respectively. The former WDA has been identified as a source of TCE in groundwater. TCE has not been detected consistently, or above the MCL in monitoring wells downgradient of the former WDA.

Previously, methylene chloride was detected as high as 220 μ g/L in monitoring well TT-MW2-22 during Second Quarter 2008. Since that time the concentration of methylene chloride has dropped to a concentration of 4.5 μ g/L during Second Quarter 2010. During this same time period, methylene chloride was reported in groundwater samples collected from monitoring wells TT-MW2-21 at concentrations ranging from below the detection limit to 7.7 μ g/L. Methylene chloride has not been detected in monitoring wells downgradient of the former WDA.

Previously, 1,4-dioxane was detected as high as 320 μ g/L in monitoring wells located in the former WDA. 1,4-dioxane was detected in monitoring wells TT-MW2-22, TT-MW2-24, and TT-MW2-37A at concentrations of 33 μ g/L, 250 μ g/L, and 13 μ g/L, respectively during the Second Quarter 2010. The former WDA has been identified as a source of 1,4-dioxane in groundwater. 1,4-dioxane has been detected in downgradient monitoring wells. The 1,4-dioxane DWNL is 1 μ g/L.

Previously, RDX was reported in groundwater samples collected from monitoring well TT-MW2-24 located at the former WDA at concentrations as high as $5.9 \,\mu\text{g/L}$. During Second Quarter 2010 RDX was detected in TT-MW2-24 at a concentration of $3.2 \,\mu\text{g/L}$. RDX has not been detected in other wells located in or downgradient of the former WDA. The DWNL for RDX is $0.3 \,\mu\text{g/L}$.

Lower Canyon and Riparian Corridor

Perchlorate and 1,4-dioxane have been detected in the lower portion of Laborde Canyon downgradient from the former WDA. Perchlorate has also been detected in the riparian corridor south of the property boundary. In the lower section of Laborde Canyon, perchlorate was detected at concentrations as high as 4,700 μ g/L, up to 519 μ g/L at the southern Site boundary, and up to 0.18 μ g/L in the riparian corridor south of the southern Site boundary. During Second Quarter 2010 and Third Quarter 2010 perchlorate in the groundwater was detected at concentrations ranging from 6,600 μ g/L in the lower section of Laborde Canyon to below the MDL in the riparian corridor. No source of perchlorate has been identified in the lower canyon or at the southern Site boundary; the perchlorate appears to have originated in the former WDA.

1,4-dioxane was reported in groundwater samples collected from monitoring wells TT-MW2-5 and TT-MW2-9S, which are located in or downgradient of the former WDA, at concentrations of $0.92~\mu g/L$ to $8.5~\mu g/L$ respectively during Second Quarter 2010. These detections are consistent with previous detections in these wells. 1,4-dioxane has not been detected in other wells located in the lower canyon or riparian corridor area. The source of the 1,4-dioxane appears to be the former WDA.

Former Wolfskill Property

On the former Wolfskill property, south of the southern Site boundary, perchlorate was detected in TT-MW1-19S during Second Quarter 2010 and Third Quarter 2010 at concentrations of $5.0 \,\mu\text{g/L}$ and $4.8 \,\mu\text{g/L}$ respectively. These results are consistent with historic results. Perchlorate has not

been detected in monitoring well TT-MW2-20S or TT-MW2-20D, located approximately one half mile south of TT-MW2-19S.

Based on the data available at this time, the extent of the TCE, methylene chloride, and RDX plumes in groundwater appear to be isolated to small areas and do not extend offsite. The 1,4-dioxane plume is limited to the WDA and lower Laborde Canyon and does not appear to extend offsite. The perchlorate plume does appear to extend offsite, but the offsite extent of perchlorate appears to be limited by naturally-occurring phytoremediation or biodegradation in the riparian corridor south of the southern Site boundary. The perchlorate detected in monitoring well TT-MW2-19S located on the former Wolfskill property appears to be an isolated impact resulting from preferential flow in higher-conductivity alluvium during a prolonged period of heavy precipitation in the past.

4.3 Natural Attenuation Sampling

The objective of the MNA sampling and analyses effort is to understand the geochemical characteristics upgradient, within and downgradient from the Test Bay Area and WDA perchlorate plumes. A preliminary evaluation of MNA suggests that there is limited potential for natural perchlorate biodegradation, except within the riparian area downgradient of the WDA perchlorate plume.

The data obtained from the MNA sampling will be combined with the data obtained during the Second Quarter 2010 site-wide natural attenuation study to develop a contaminant attenuation CSM to identify areas of the Site where conditions may be conducive to natural attenuation of perchlorate, chlorinated solvents, and 1,4-dioxane.

4.4 Temporal Trend Analysis

Groundwater sampling results from the 64 wells and 8 surface water locations sampled in 2010 were included in the temporal trend analyses. Temporal trend analysis of perchlorate, TCE, methylene chloride, 1,4-dioxane, and RDX (the Site COPCs) were performed using data from Second Quarter 2004 to Third Quarter 2010. This temporal trend analysis updates the analysis performed following completion of the Third Quarter 2009 monitoring event (Tetra Tech, 2010a). The temporal trends were analyzed using Mann-Kendall and linear regression methods. The magnitude of the trends is presented as a change in concentration per year.

The number of increasing or probably increasing trend wells has increased from 6 wells in 2009 to 11 wells in the 2010 temporal trend analyses. This increase is attributed to the relatively large number of new wells that have been installed in the last several years (41 new wells since 2008), and the number of wells that have historically yielded no trend. The number of decreasing trend, probably decreasing trend, and stable trend wells has increased during this period as well. Tables 4-1 and 4-2 display a summary of the historic trend analyses for TCE and perchlorate.

Table 4-1 Historic TCE Trend Summary

	Locations Tested

Notes:

A summary of the trend analysis results for the 11 increasing or probably increasing trend locations is presented in Table 4-3. The Second Quarter 2010 concentrations and percent change that these increases represent with respect to the mean of the data used to calculate each trend is also presented in Table 4-3. The increasing trend in monitoring wells TT-MW2-1, TT-MW2-11, TT-MW2-14, and TT-MW2-17S represent less than a 20 percent change.

Area K – Area K is one of the primary source areas for the Site COPCs. Four of the 11 wells identified with increasing trends were from monitoring wells located in this area. Of these four wells, two (TT-MW2-17S and TT-MW2-29C) are wells which have low-level detections of the increasing concentration analyte. Three of the wells in Area K had decreasing or probably decreasing trends. The remaining 22 wells located in Area K were either non-detect for all analytes or displayed no trend or a stable trend.

 $Area\ M$ – Area M is a secondary source area for the Site COPCs. One of the 11 wells identified with increasing trends was from a monitoring well located in this area. The remaining two wells located in Area M were either non-detect for all analytes or displayed no trend or a stable trend.

Former Waste Discharge Area – The former WDA is one of the primary source areas for the Site COPCs. Three of the 11 wells identified with increasing trends were from monitoring wells located in this area. Of these three wells, one (TT-MW2-21) one only has low-level detections of the increasing concentration analytes. The remaining three wells located in the former WDA were either non-detect for all analytes or displayed no trend or a stable trend.

Lower Canyon Area (Downgradient or Crossgradient of the Former Waste Discharge Area) — There are no known contaminant sources in the lower canyon area. Two of the 11 wells with increasing trends identified were from monitoring wells located in this area. Three of the wells in the lower canyon had decreasing or probably decreasing trends. The remaining 10 wells located in lower canyon were either non-detect for all analytes or displayed no trend or a stable trend. Two of the Sites guard wells are located in this area. Guard wells TT-MW2-41A and TT-MW2-42A are located approximately 600 feet and 1,000 feet south of the Site boundary respectively, and displayed non-detect or stable COPC trends. It is believed that natural attenuation of perchlorate may be occurring in the riparian area between the Site boundary and the guard wells. The COPC plumes diminish significantly through this area.

Former Wolfskill Property – There are no known contaminant sources on the former Wolfskill Property. One of the 11 wells with increasing trends identified was from monitoring wells located in this area. One of the wells in the lower canyon had a decreasing trend. The remaining two wells located in the lower canyon were either non-detect for all samples analyzed or displayed either no trend or a stable trend. The remaining Site guard wells are located in this area. Guard wells TT-

MW2-19S and D and TT-MW2-20 S and D are located approximately 0.9 miles and 1.7 miles south of the Site boundary respectively. Guard wells TT-MW2-19S, TT-MW2-19D, TT-MW2-20S and TT-MW2-20D primarily displayed non-detect, no trend or decreasing COPC trends, with the exception of TT-MW2-19S, which had an increasing perchlorate trend.

The relatively short time frame represented by the data analyzed, (half of the wells have less than two years of data), makes it difficult to know the reason for the trends observed. The trends may represent plume migration or seasonal fluctuations in concentration due to the continuing drought conditions experienced at the site. As the period of record grows, and the number of data points increases, the trends should become better defined and more reliable long term trends should emerge from the data. In general, the plume morphology has not changed and the majority of the wells and the surface water locations display a stable trend, no trend, or are non-detect.

4.5 Groundwater Monitoring Program and the Groundwater Quality Monitoring Network

4.5.1 Groundwater Sampling Frequency

The primary criterion utilized in determining the sampling frequency of a monitoring well is the well classification (i.e., function of each well; Tetra Tech, 2007b). Groundwater monitoring well classifications are based on the evaluation of the temporal trends, spatial distribution analyses, and other qualitative criteria. During the previous reporting period, horizontal extent wells, vertical distribution wells, increasing contaminant trend wells, background wells, guard wells, and new wells were sampled. Table 4-4 presents a summary of the frequency of groundwater sampling by well classification.

Table 4-4 Well Classification and Sampling Frequency

Well Classification	Frequency							
Horizontal Extent Wells	Semiannual							
Vertical Distribution Wells	Semiannual							
Increasing Contaminant Trend Wells	Semiannual							
Background Wells	Annual							
Remedial Monitoring Wells	Varies, based on remedial action proposed							
Guard Wells	Semiannual							
New Wells	4 Quarters then reclassify							
Redundant Wells Suspend (no sampling)								
Groundwater Sampling and Analysis Plan. Beaumont, California, May, 2007 (Tetra T	, Lockheed Martin Corporation, Beaumont Site 2, Tech 2007b).							

4.5.2 Proposed Changes

Twenty-four quarters of water quality monitoring have been conducted at the Site since the September 2004 well installation activities. Groundwater samples have been routinely analyzed for VOCs and perchlorate. Selected testing for CAM 17 metals, general minerals, 1,4-dioxane, RDX, NDMA, 1,2,3-TCP and hexavalent chromium has also been performed. A groundwater monitoring SAP was prepared to optimize and better define the GMP at the Site (Tetra Tech, 2007b). In concurrence with the DTSC, groundwater monitoring will be performed in accordance with the SAP.

Monitoring wells TT-MW2-25 through TT-MW2-43 have now been sampled for a year, and reclassifications are proposed. Unless otherwise specified below, these changes are listed in Table 4-5.

The sampling frequency for wells with an increasing trend may be increased to semiannual if the magnitude of the trend and the wells location warrant an increased frequency. Regardless of the outcome of the trend analysis, guard wells will continue to be sampled semiannually. The monitoring frequency of all other wells exhibiting an increasing trend will be evaluated on a case-by-case basis, with particular attention given to the magnitude of the trend and the location of the well.

Based on the results of the temporal trend analysis and the magnitude of their trends, continued semiannual sampling for increasing or probably increasing concentration trend wells TT-MW2-29C located in Area K, TT-MW2-21, TT-MW2-22 and TT-MW2-37A located in the former WDA, TT-MW2-9S and TT-MW2-26 located in the lower canyon area, and TT-MW2-19S located on the former Wolfskill Property is proposed.

Due to the limited magnitude of their trends it is proposed that monitoring wells TT-MW2-1, and TT-MW2-14 located in Area K, and TT-MW2-11 located in Area M return to their previously approved sampling frequencies and TT-MW2-17S located in Area K remain at its previously approved sampling frequency.

The analytical scheme is evaluated annually during the Second Quarter of each year and changes may be proposed to accommodate expanded site knowledge or changing Site conditions. The classifications of the wells in the network and the corresponding sampling frequency is also evaluated annually during the Second Quarter of each year and modified to accommodate expanded site knowledge or changing site conditions.

The proposed groundwater analytical program includes the following suite of analysis:

- 1. Perchlorate semiannually or annually in all monitored wells by EPA Method E332.0,
- 2. VOCs, including oxygenates, for all new wells and semiannually or annually for select wells by EPA Method SW 8260B,
- 3. 1,4-dioxane semiannually or annually for select wells by EPA Method SW 8270 SIM,
- 4. CAM 17 Metals (total), for all monitored wells with historic detections above the MCL by EPA Method SW 6010B and SW 7470A annually until background concentrations for metals have been evaluated and the nature of the metals concentrations detected in the groundwater have been determined by the human health risk assessment,
- 5. CAM 17 Metals (dissolved), for all water table wells where the water level and the well screen are both less than 25 feet below ground surface, and with historic detections above the MCL by EPA Method SW 6010B and SW 7470A annually until the nature of the metals concentrations have been evaluated in the ecological risk assessment,
- 6. RDX annually for select wells by EPA Method SW 8330,

Natural attenuation parameter analyses will be discontinued pending the results of the Site-wide natural attenuation study, which is currently underway. Recommendations for future natural attenuation parameter sampling will be discussed in the upcoming natural attenuation study report.

As previously noted, sampling for NDMA will be discontinued for future groundwater monitoring events.

General mineral analyses will be performed on selected wells to determine cation and anion geochemistry for the aquifer. General minerals analysis will not be performed on new wells for a minimum of six months after installation to allow the aquifer to stabilize. The following suite of general mineral analysis will be performed during selected groundwater sampling events:

- 1. Total Dissolved Solids (TDS) by EPA Method E160.1,
- 2. Chloride, nitrate (as nitrogen) and sulfate by EPA Method E300.0, and
- 3. Carbonate and bicarbonate (as calcium carbonate) by EPA Method E310.1,
- 4. Calcium, manganese, potassium, and sodium by EPA Method SW6010.

Table 4-5 summarizes the proposed monitoring well sampling schedule and frequency.
