VIA PRIVATE CARRIER

Mr. James R. Carroll
Program Administrator
Land Restoration Program
Land Management Administration
Maryland Department of the Environment
1800 Washington Boulevard, Suite 625
Baltimore, Maryland 21230

Subject: Transmittal of the Block E Soil Remedial Action Plan
Lockheed Martin Corporation – Middle River Complex
2323 Eastern Boulevard, Middle River, Baltimore County, Maryland

Dear Mr. Carroll:

For your review please find enclosed two hard copies with a CD of the above-referenced document. This Remedial Action Plan for Tax Block E of the Lockheed Martin Middle River Complex in Middle River Maryland, provides the background, supporting documentation, framework and recommended remedy for Tax Block E soil.

If possible, we respectfully request to receive MDE's document review comments by May 24, 2019.

Please let me know if you have any questions. My office phone is (301) 548-2209.

Sincerely,

Thomas D. Blackman
Project Lead, Environmental Remediation

GLOSSARY

applicable or relevant and appropriate requirements (ARARs)—Environmental cleanup standards and requirements (i.e., federal and state laws and regulations) that must be attained during cleanup and maintained at project completion (required by the federal Comprehensive Environmental Response, Compensation, and Liability Act [CERCLA]) and its implementing regulations.

Aroclor—Aroclor is the trade name for a polychlorinated biphenyl (PCB; see glossary term) mixture produced from approximately 1930 to 1979. Aroclors have a distinguishing suffix number that indicates the degree of chlorination as follows: the first two digits generally refer to the number of carbon atoms in the phenyl rings (this is 12 for PCBs), the second two numbers indicate the percentage of chlorine by mass in the mixture. For example, the name Aroclor 1254 means that the mixture contains approximately 54% chlorine by weight.

background (background level)—As defined by the United States Environmental Protection Agency (USEPA), substances in the environment that are not influenced by releases from a site and usually described as naturally occurring or anthropogenic. Naturally occurring is defined as substances in the environment in forms that have not been influenced by human activity. Anthropogenic is defined as natural and human-made substances in the environment because of human activities, but not specifically related to the site in question.

benzo(a)pyrene-equivalent (BaPEq)—A risk-weighted, calculated concentration representing the additive effects of seven polycyclic aromatic hydrocarbons (PAHs): benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, benzo(k)fluoranthene, indeno(1,2,3-cd)pyrene, and chrysene. The BaPEq value is a calculated concentration accounting for the combined toxicity of individual PAHs relative to benzo(a)pyrene. Toxicity equivalency factors (TEFs) are used to convert each individual PAH concentration into an equivalent concentration of benzo(a)pyrene, and the sum of these equivalent concentrations (for the seven PAHs mentioned above including benzo(a)pyrene) is the calculated BaPEq concentration. BaPEq can be calculated based on actual concentrations, using positive detections only, or can be calculated conservatively by using both positive detections and surrogate values equal to half the detection limit for samples without detections. The latter method of calculation assumes the seven PAHs might have been present at concentrations below laboratory detection limits in samples in which they were not detected.

carcinogen—A substance that can cause cancer.

chemical(s) of concern (COC)—Chemicals identified through the baseline risk assessment that might potentially cause unacceptable (by regulatory definition) adverse effects to human health and/or ecological receptors.

chemical(s) of potential concern (COPC)—Chemicals identified through a preliminary screening, typically in the first step of a baseline risk assessment, which should be considered further in the site evaluation.

cleanup—Actions to address a release or threat of release of a hazardous substance that could affect humans and/or the environment. The term "cleanup" is sometimes used interchangeably with the terms remedial action, removal action, response action, or corrective action.

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)—Commonly called Superfund, a federal law passed in 1980 and extensively amended several times, most significantly in 1986 by the Superfund Amendments and Reauthorization Act (SARA). Among other things, this law addresses the remediation of sites where one or more hazardous substances have been disposed of or released to the environment.

conceptual site model (CSM)—A written and/or schematic representation of an environmental system and the physical, chemical, and biological processes that affect the transport of chemicals from sources through environmental media (e.g., air, soil, water, or sediment) to humans and ecological receptors in the system. The CSM is periodically revised as additional data become available at a site.

congeners—Compounds that have similar chemical structures or belong to closely related chemical families.

containment—A technology or design that prevents the movement of contaminants outside of an originating source or property, or onto an outside property, or beyond an agreed compliance line or zone, but does not necessarily treat or remove the contaminants.

Controlled Hazardous Substance (CHS) regulations—Regulatory requirements for management and disposal of hazardous waste in Maryland, found in Code of Maryland Regulations (COMAR) 26.14. Remediation of hazardous waste sites is accomplished through a three-phase process: (a) assessment, (b) cleanup, and (c) operation, maintenance, and monitoring.

ex situ—Away from the original location or place where pollutants are found; in this report, ex situ means on-site and at the surface, but not in place. For example, an ex situ treatment of contaminated soil or groundwater will remove (through pumping or digging, for example) the soil or groundwater from where it was found, and subsequently subject it to a treatment process (see also in situ, below).

exposure assessment—One step in the human or ecological risk assessment process, an exposure assessment measures or estimates the magnitude, frequency, duration, and route of exposure for a receptor (human or ecological) that might come into contact with an environmental contaminant (for example, by touching contaminated soil). The most quantitative result achieved by an exposure assessment is the calculation of an exposure or intake dose (i.e., the amount to which the receptor is exposed).

exposure pathway—The path from contaminated media (including air, soil, sediment, water, or food) to human and ecological receptors.

exposure route—The way a contaminant enters an organism after contact; i.e., by ingestion, inhalation, or dermal absorption.

exposure scenario—A tool to develop estimates of potential exposure, dose, and risk. An exposure scenario generally includes facts, data, assumptions, inferences, and, sometimes, professional judgment about how the exposure could occur.

free product—The presence of contamination in the subsurface as a separate liquid phase in soil, groundwater, surface water, or multiple media. Usually consists of a manufactured-product liquid (e.g., dieletric fluid, oil, etc.) that has been spilled or released to environmental media and is present in its original state and composition (e.g., not dissolved in water, not sorbed to soil).

hazard index (HI)—A numerical indicator of the potential for adverse noncarcinogenic health effects (i.e., any health effect other than cancer) that is derived by summing the individual-chemical hazard quotients. A hazard index greater than 1 suggests that adverse health effects are possible, whereas a hazard index equal to or less than 1 does not.

hazard quotient (HQ)—The ratio of estimated site-specific exposure to a selected toxicity threshold for a single chemical, which is either the level at which no adverse health effects are likely to occur (i.e., the no-observed-adverse-effect level) or at which effects are likely to occur (i.e., the lowest-observed-adverse-effect level).

hazardous substance—From CERCLA, a hazardous substance is: "(A) any substance designated pursuant to section 311(b)(2)(A) of the Federal Water Pollution Control Act (33 U.S.C. 1321[b][2][A]), (B) any element, compound, mixture, solution, or substance designated pursuant to section 9602 of this title (i.e., CERCLA), (C) any hazardous waste having the characteristics identified under or listed pursuant to section 3001 of the Solid Waste Disposal Act (42 U.S.C. 6921) (but not including any waste the regulation of which under the Solid Waste Disposal Act [42 U.S.C. 6901 et seq.] has been suspended by Act of Congress), (D) any toxic pollutant listed under section 307(a) of the Federal Water Pollution Control Act (33 U.S.C. 1317[a]), (E) any hazardous air pollutant listed under section 112 of the Clean Air Act (42 U.S.C. 7412), and (F) any imminently hazardous chemical substance or mixture with respect to which the Administrator has taken action pursuant to Section 7 of the Toxic Substances Control Act (15 U.S.C. 2606). The term does not include petroleum, including crude oil or any fraction thereof, which is not otherwise specifically listed or designated as a hazardous substance under subparagraphs (A) through (F) of this paragraph, and the term does not include natural gas, natural gas liquids, liquefied natural gas, or synthetic gas usable for fuel (or mixtures of natural gas and such synthetic gas)."

homolog—Homologs are a way of grouping polychlorinated biphenyl (PCB) congeners by the number of chlorine atoms they have; this can vary from one to ten. All the PCB chemicals that have the same number of chlorine atoms are said to belong to the same homolog group. For example, there are 11 different congeners in the 2-chlorine homolog group and 42 different congeners in the 4-chlorine homolog group. Laboratory analysis for PCB homologs can reliably measure the amount of PCBs present in a sample if it is likely to have been subjected to environmental conditions that could alter its congener composition.

impacted soil—Soil identified in the residual-risk analysis (RRA) that has chemical(s) of concern (COC) concentrations associated with an incremental lifetime cancer risk (ILCR) greater than one-in-100,000 (1×10-5) and hazard index (HI) greater than 1.

in situ—In this report, in situ means on-site and in place. For example, an in situ treatment of contaminated soil or groundwater will treat these environmental media in place, without removing the soil or groundwater to treat it (see also ex situ, above).

institutional controls—Non-engineering (administrative) measures intended to affect human activities in such a way as to prevent or reduce exposure to hazardous substances. They are typically used in conjunction with, or supplemental to, other measures such as waste removal, treatment, or containment. Institutional controls fall into four categories: governmental controls, proprietary controls (such as deed restrictions), enforcement tools, and informational devices.

iteratively—In the context of the residual-risk assessment, iteratively means the repetition of a step in the assessment until the desired outcome or goal has been achieved.

land use controls (LUCs)—Engineered and non-engineered (administrative) controls formulated and enforced to regulate current and future land use options. Engineered controls include fencing and signs. Non-engineered controls, referred to as institutional controls, typically consist of administrative restrictions that prohibit certain types of development and/or groundwater use.

Middle River Complex (MRC)—A site in Baltimore County, Maryland occupied by Lockheed Martin's Mission Rotary and Mission Systems and General Electric's MRA Systems, Inc. subsidiary known as Middle River Aircraft Systems, or MRAS.

National Oil and Hazardous Substances Pollution Contingency Plan (NCP)—Federal regulations outlining a framework for responding to a spill or release, or threat of release, of oil or a hazardous substance. It establishes a National Response Team, headed by USEPA, and outlines requirements for accident reporting, spill containment, and cleanup.

nondetect—Data point for which the chemical of interest was not detected in the chemical analysis of an environmental sample, usually referred to as a laboratory detection or reporting limit.

polychlorinated biphenyls (PCBs)—PCBs are manmade organic chemicals manufactured and used in construction materials and electrical products. PCBs belong to the broad family of organic chemicals known as chlorinated hydrocarbons. They vary in consistency from thin, light-colored liquids to yellow or black waxy solids. The non-flammability, chemical stability, high boiling point, and electrical insulating properties of PCBs led to their widespread use in hundreds of industrial and commercial applications, including electrical transformers, hydraulic equipment, thermal insulation, fluorescent lights, oil-based paints, carbonless copy paper, and many other industrial applications. The manufacture of PCBs was banned in the U.S. in 1979.

polycyclic aromatic hydrocarbons (PAHs)—A group of semivolatile organic chemicals often found together. PAHs are created when products such as coal, oil, gas, and garbage are

burned, but the burning is incomplete. They can also be found in the environment as a result of natural processes such as wildfires. PAHs are a concern because they persist in the environment, meaning they do not readily degrade, and can stay in the environment for long periods.

preliminary remedial goal (PRG)—An acceptable (according to regulations) contaminant level or range of levels for a given environmental medium (such as soil, water, or air) that can support the evaluation of remedial alternatives. Although PRGs are established based on readily available information, the final regulatorily acceptable exposure levels should be determined based on the results of the baseline risk assessment and evaluation of the expected exposures and associated risks for each alternative.

recognized environmental condition (REC)—An environmental condition redefined by ASTM International (ASTM) E 1527-05 as "the presence or likely presence (as documented in public or other available records) of any hazardous substances or petroleum products on a property, under conditions that indicate a potential for an existing release, a possible past release, or a material threat of a release of the hazardous materials into structures or into the soil, groundwater, or surface water of the property."

remediation—The process of correcting and/or cleaning up environmental contamination, governed by various federal and state laws, regulations, and other requirements.

response action—An action or series of actions to reduce, isolate, or remove contamination from an environmental medium (e.g., soil, air, groundwater, surface water), with the goal of preventing harmful exposure to people or animals and reducing its impact to the environment.

remedial action objective (RAO)—Cleanup objective specifying contaminants to be cleaned up and the level (i.e., the reduction in contaminant concentrations), area, and time required to achieve cleanup adequate to protect human health and the environment.

remedial action plan (RAP)—Remedial action is defined in the National Contingency Plan in part as "those actions consistent with a permanent remedy taken instead of, or in addition to, a removal action(s) in the event of a release or threatened release of a hazardous substance into the environment, to prevent or minimize the release of hazardous substances so that they do not migrate or cause substantial danger to present or future public health or welfare, or the environment." The RAP details the remedial measures to be taken to minimize environmental and health risks associated with known release(s) of hazardous substances. Depending on known or anticipated risks to human health and the environment, appropriate action can include site closure, monitoring and data collection, active or passive remediation, containment, or imposition of institutional controls.

risk assessment—A qualitative or quantitative evaluation of the risk posed to human health and/or the environment by the actual or potential presence or release of hazardous substances, pollutants, or contaminants.

site—The area of investigation; for this remedial action plan, the site is Block E.

standard proctor—A standardized mechanical testing method used to determine the compaction property of soil. The test is described in American Association of State Highway and Transportation Officials (AASHTO) specifications T99 and ASTM International (ASTM) standard D698-12.

thermal desorption—A thermal soil-vapor remediation technique by which thermal conductive heating (to 350º Celsius or 662º Fahrenheit) is used to heat the predetermined treatment zone while a slight vacuum is applied to the subsurface to extract soil vapors.

total petroleum hydrocarbons (TPH)—The concentration (or mass) of petroleum hydrocarbon constituents present in a given amount of air, soil, or water.

toxicity equivalency factor (TEF)—Estimates of compound-specific toxicity relative to the toxicity of an index chemical (e.g., benzo[a]pyrene). TEFs are used in a risk assessment to evaluate the risks associated with exposure to a mixture of similar compounds for human or ecological receptors.

Toxic Substance Control Act (TSCA)—Federal legislation originally enacted in 1976 to regulate chemicals produced or imported into the United States. TSCA and its implementing regulations specifically address use and disposal of PCBs.

trichlorobenzene (TCB)—1,2,4-Trichlorobenzene is an aromatic, colorless organic liquid that was commonly used as a solvent to make other organic chemicals and as an additive in wood preservatives.

volatile organic compounds (VOCs)—A group of organic chemicals that will vaporize or evaporate into the atmosphere at room temperature. They often have a sharp smell and can come from many products, such as office equipment, adhesives, carpeting, upholstery, paints, petroleum products, solvents, and cleaning products. Trichloroethene is an example of a VOC.

Voluntary Cleanup Program (VCP)—A Maryland Department of the Environment (MDE)-administered program providing state oversight for voluntary cleanups of properties contaminated with hazardous substances. The program was established in 1997 by an agreement between MDE and the United States Environmental Protection Agency (USEPA). The program provides liability protection for participants such that USEPA will consider sites in the VCP of "no further interest" provided they are successful in cleanup and MDE issues a "No Further Requirements Determination" or "Certificate of Completion." The program goal is to increase the number of sites cleaned by streamlining the cleanup.

EXECUTIVE SUMMARY

Environmental stewardship is an important aspect of the Lockheed Martin Corporation (Lockheed Martin) commitment to the communities in which we operate. Accordingly, the corporation has assumed responsibility to assess and clean up environmental impacts at the Lockheed Martin Corporation Middle River Complex (MRC) at 2323 Eastern Boulevard in Middle River, Maryland (see Figure 1-1). Tetra Tech, Inc. (Tetra Tech) has prepared this remedial action plan (RAP) for soil for a portion of the Middle River Complex known as Block E (see Figure 2-1) on behalf of Lockheed Martin Corporation and in accordance with requirements administered by the Maryland Department of the Environment (MDE) Land Restoration Program under Administrative Consent Order ACO-SAR-MDE0746-2015-1-01.

The Middle River Complex consists of Tax Blocks A (two parcels), B, D, D Panhandle, E (two parcels), F, G, H, and I. Block E as described herein includes the main Block E parcel (15.433 acres) and a smaller lot at the southeastern corner of Block E known as "Block E2" (0.533 acres). Block E consists of three recognized environmental conditions (RECs): (1) the area of former Building D (REC #1), (2) the product pipeline (REC #2), and (3) the area of a former 500,000-gallon fuel-oil aboveground storage tank (AST) and associated tank (REC #3) (see Figure 2-3). Polychlorinated biphenyls (PCBs) have been detected over a portion of Block E, so remediation will be performed in accordance with the federal Toxic Substances Control Act (TSCA) (40 CFR 761.61(c) "Risk-Based Disposal Approval" process.

The long-term goal for this remedial action plan and related remedial actions at the site is to appropriately address the environmental impacts within Block E and receive a "No Further Action" letter from the Maryland Department of the Environment under an industrial future land use and restriction category. Remediation targeted for future industrial land use is being proposed to meet the current and projected future use of the property. This does not prohibit Block E from future development for residential, commercial, or recreational use, although additional remedial activities might be required.

Lockheed Martin Corporation completed remedial action plans for Blocks D, D-Panhandle, F, G, and H in late 2013 and early 2014, completed remediation in these blocks in 2016, and received "No Further Action" letters for these parcels in 2017. Remediation to address Lockheed Martin predecessors' use and impacts at Block I has been deferred to the future because Block I includes an active industrial complex currently occupied by MRC tenants, including MRA Systems, Inc. Blocks A and B include parking lots that serve the employees at Block I.

The Block E remedial action plan will be submitted in two documents (this remedial action plan and a "Risk-Based Disposal Approval" application), because the remediation of PCB impacts requires review and approval by the United States Environmental Protection Agency (USEPA), and because PCBs and other site contaminants require review and approval by the Maryland Department of the Environment. A response action for groundwater at the Middle River Complex was presented in a separate groundwater response action plan approved by the Maryland Department of the Environment in September 2012. The *in situ* groundwater bioremediation system wells and piping detailed in that plan have been installed in Block E, but the system is not yet in operation. An addendum to the groundwater response action plan (Tetra Tech, 2018c), recommending an expansion of that system and installation of a groundwater containment system and permeable reactive barrier in Block F, was approved by the Maryland Department of the Environment in July 2018. Design of that system is proceeding, and installation is anticipated to be completed in late 2019.

A feasibility study for sediment remediation in Cow Pen Creek and Dark Head Cove (adjacent to the Middle River Complex, Figure 1-1) was submitted to the Maryland Department of the Environment and the United States Environmental Protection Agency in December 2012. In 2013, both agencies approved the proposed remedial action for sediment, and a final feasibility study was submitted and was approved in 2014 (Tetra Tech, 2013b). The sediment-removal action (SRA), which removed elevated concentrations of PCBs in Dark Head Cove near Outfall 005, was completed in early 2015. The full sediment remediation was completed in 2016–2018. The remediated sediment in Dark Head Cove was impacted primarily by PCBs that likely migrated from Block E soil through the storm drainage system. The following summaries discuss the substantive elements of the Block E Soil RAP.

Nature and extent of contamination—Investigations associated with Block E have been conducted since 1998, and include record reviews, discussions with current and former Middle River Complex personnel, geophysical surveys, and soil, sediment, and groundwater sampling. Soil data collected from REC #1 (former Building D) and REC #3 (diesel fuel oil AST) within the tax block indicate that past activities have released contaminants to the surrounding environment. This contamination could be the result of the following:

- the former diesel fuel oil aboveground storage tank and associated tank (REC #3), or product line (REC #2)
- an underground storage tank (UST) containing trichloroethene (TCE) that was removed from the southeastern portion of Block E in 2013
- historical industrial operations on Block E
- former Building D operations that included several transformer rooms that used PCBs in insulating oils
- a possible release of PCBs during demolition of the former Building D

These investigations indicate that site surface soil (0 to 2 feet below the soil surface) and subsurface soil (greater than 2 feet below the soil surface) is primarily contaminated with PCBs and polycyclic aromatic hydrocarbons (PAHs). ("Soil surface" refers to the ground surface where the soil is exposed or the soil in contact with the bottom of the concrete where a foundation is present.) Polycyclic aromatic hydrocarbons are commonly found in fill material, particularly in the form of coal or wood ash, as well as in asphalt. The polycyclic aromatic hydrocarbons in Block E might be associated with fill material historically placed at the site, and are a ubiquitous contaminant at the Middle River Complex.

Exposure assessment—An exposure assessment for the site (Section 3) evaluated human health risks associated with exposure to site contaminants under current and future exposure scenarios. Its results indicate that, under regulatory standards, the site soil poses unacceptable risks to current industrial workers and future construction workers exposed to chemicals of concern (COC) in soil through dermal contact, inhalation, and ingestion. These exposure pathways are consistent with the current industrial land use of the site. However, actual exposure to workers based on the current usage is limited due to the presence of concrete and asphalt covering most of the site and the short exposure duration of current workers. Additionally, the current Block E storm-drain system has

been identified as a possible complete exposure pathway, because PCB contaminants could migrate through the system and ultimately be released to Dark Head Cove.

The chemical families of PCBs and polycyclic aromatic hydrocarbons are the primary risk drivers identified for industrial workers in Block E in the *Human Health Risk Assessment (HHRA) for Blocks D, E, F, G, and H Soils* (Tetra Tech, 2012f.) PCBs, polycyclic aromatic hydrocarbons, 1,2,4-trichlorobenzene (1,2,4-TCB), total petroleum hydrocarbon (TPH)-diesel-range organics (DRO), and trichloroethene have been identified at concentrations exceeding industrial risk-based criteria in surface and subsurface soil at Block E. Trichlorobenzene compounds are co-located with PCBs, consistent with their common use as part of the PCB-based insulating fluids within transformers. Trichloroethene impacts are being addressed as part of the groundwater response action.

Remedial action objectives—To obtain a "No Further Action" letter under an industrial future land use, the following remedial action objectives must be met for impacted soil at Block E (see Section 4):

Remedial action objective	Description
1	Reduce site-related chemicals of concern in Block E soil to not exceed a cumulative human health cancer-risk limit of 1×10^{-5} and a cumulative non-carcinogenic hazard index of 1 for industrial workers and construction workers.
2	Prevent transfer of PCBs to the extent practicable from surface soil and storm drains to discharged stormwater at concentrations that would impact the sediment remedy.
3	Prevent leaching to the extent practicable of PCBs and 1,2,4-trichlorobenzene from soil to groundwater at concentrations that would impact surface water concentrations.

Human health risk assessment and residual risk analysis—The human health risk assessment (HHRA) for Blocks D, E, F, G, and H soil (Tetra Tech, 2012f) identified chemicals of concern in soil that would require remediation to meet remedial action objective No. 1 for typical industrial and construction worker receptors of concern. The risk assessment consisted of the following six components:

- data evaluation
- toxicity assessment
- exposure assessment
- risk characterization

- uncertainty analysis
- development of preliminary remedial goal options

In 2018, a residual risk analysis (RRA) was prepared to account for changes in screening criteria and to incorporate additional sampling data collected after the 2012 human health risk assessment (Tetra Tech, 2018d). The residual risk analysis used a risk assessment approach to select remediation locations and iteratively remove soil sample locations from high to low concentrations to achieve the following risk management goals, established by the Maryland Department of the Environment:

- Cumulative cancer and noncancer risk for receptors exposed to chemicals of concern in an exposure unit (EU) no greater than 1×10^{-5} (i.e., a one-in-100,000 excess probability of developing cancer) and a hazard index (HI) of 1, for cancer risk and noncancer effects, respectively.

- "Hot spot" areas in soil, defined as a location associated with a cancer risk estimate exceeding 1×10^{-4} (i.e., a one-in-10,000 excess probability of developing cancer), or a hazard index greater than 100, will be addressed by the remedial action plan to appropriately reduce the risk.

The residual risk analysis identified locations that must be remediated to achieve risk management goals, while ensuring that representative soil concentrations do not exceed the risk-based preliminary remediation goals (PRGs) established for Block E soil[1] (presented below). The human health risk assessment identified PCBs (predominantly Aroclor mixture 1260), carcinogenic polycyclic aromatic hydrocarbons evaluated as benzo(a)pyrene-equivalents (BaPEq)[2], and 1,2,4-trichlorobenzene as chemicals of concern for exposure to surface soil in Block E (Tetra Tech, 2012f). No new chemicals of concern were identified for surface soil in the residual risk

1 Tom D. Blackman to James R. Carroll, Preliminary Remediation Goals for Industrial and Construction Workers: Block E Soil Remediation, September 2017.

2 Per current United States Environmental Protection Agency (USEPA) guidance (USEPA, 1993b), concentrations of benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene can be combined in an adjusted risk-weighted concentration that is expressed in terms of benzo(a)pyrene toxicity. This calculated value, called a benzo(a)pyrene equivalent concentration (BaPEq), uses USEPA recommended toxicity equivalency factors (TEFs) to estimate the potency of each of these PAH compounds relative to that of benzo(a)pyrene. The TEFs are then used to convert each individual PAH concentration (for the purposes of this report, positive detections only) into an equivalent concentration of benzo(a)pyrene; these values are summed to arrive at the calculated BaPEq concentration. Details outlining the BaPEq calculation are in Appendix F.

analysis after incorporating the data collected subsequent to the 2012 human health risk assessment.

For subsurface soil, the human health risk assessment results indicate that benzo(a)pyrene-equivalents, Aroclor 1254, Aroclor 1260, and 1,2,4-trichlorobenzene are chemicals of concern (Tetra Tech, 2012f). Although not identified as a chemical of concern in the human health risk assessment, trichloroethene was also considered a chemical of concern for subsurface soil in the residual risk analysis. Trichloroethene was detected near the groundwater table at elevated concentrations in subsurface soil in the southeastern corner of Block E after the discovery of an underground storage tank just outside the building foundation. This underground storage tank, removed in 2013, contained high concentrations of trichloroethene; groundwater remediation is planned in this area. Remediation of trichloroethene is addressed via the groundwater response action; details of soil sampling for trichloroethene will be included in the groundwater system design documents.

The residual-risk analysis (Section 4) identified areas of impacted soil that require remediation to meet remedial action objective No. 1 (to reduce site-related chemicals of concern to less than cumulative carcinogenic- and noncarcinogenic-risk levels acceptable for industrial and construction workers). Residual risk analysis involves sequentially "removing" the concentrations of contaminated soil samples from the risk calculation, beginning with the highest concentration and working down, until the average soil concentrations for the primary chemicals of concern attain the human health risk goal with a 95% certainty. These blocks of affected soil are physically remediated in Block E to achieve the specified risk goals. Residual risk analysis was performed on soil from zero to two feet below soil surface (surface soil), and on soil from two to 20 feet below soil surface. The risk assessment and residual risk analysis are summarized in Section 4.

Preliminary remedial goals—To help reach remedial action objective No. 1, for each chemical of concern, risk-based preliminary remediation goals (PRGs) were developed for industrial and construction workers exposed to chemicals of concern in surface and subsurface soil at Block E. These risk-based preliminary remedial goals for Tax Block E soil were developed as target levels to help identify locations that must be remediated to achieve risk management goals. The

preliminary remedial goals are guidelines to achieve the cancer and noncancer risk-management goals established for the project. The risk-based PRGs are provided in the table below.

Preliminary Remedial Goals for Industrial and Construction Workers

Chemical of concern	Surface soil (mg/kg)	Risk-based basis for preliminary remediation goals	Subsurface soil (mg/kg)	Risk-based basis for preliminary remediation goals
Aroclor 1254	7[(1)]	Construction worker; hazard index = 1	7 [(2)]	Construction worker; hazard index = 1
Total PCBs; Aroclor 1260	10[(3)]	Industrial worker; 1×10^{-5} cancer risk level	58[(3)]	Construction worker; 1×10^{-5} cancer risk level
Benzo(a)pyrene-equivalent	2.9[(3)]	Industrial worker; 1×10^{-5} cancer risk level	10[(2)]	Construction worker; hazard index = 1
Trichloroethene	3.9[(1)]	Construction worker; hazard index = 1	3.9[(2)]	Construction worker; hazard index = 1
1,2,4-Trichlorobenzene	330[(1)]	Industrial worker; hazard index = 1	530[(2)]	Construction worker; hazard index = 1

Notes:

(1) Lowest value from cancer- and noncancer-based preliminary remediation goals calculated for industrial- and construction-workers.

(2) Lowest value from cancer- and noncancer-based preliminary remediation goals calculated for construction workers.

(3) The cancer-risk-based PRGs for these chemicals were adjusted to assure that the *cumulative* cancer risk resulting from exposure to both total PCBs and BaPEq does not exceed 1×10^{-5}.

Remedial action alternatives—After identifying the remedial action objectives, remedial action alternatives for soil were then identified and evaluated (see Sections 5.2 and 5.3). Various technologies and process options were considered and separated into seven general response-action categories. These include "no action," "limited action," "containment," "removal," "*in situ* treatment," "*ex situ* treatment," and "excavation and disposal" (see Table 5-5 for more information). A detailed screening of the technologies and process options with respect to effectiveness, implementability, and relative cost was conducted from which remedial alternatives were assembled. The remedial alternatives were then evaluated using several criteria. The first two criteria are *threshold criteria* which all alternatives must meet: overall protection of human health and the environment and compliance with applicable or relevant and appropriate requirements. The next set of criteria, the *balancing criteria*, are long-term effectiveness and permanence; short-term effectiveness; environmental impacts; reduction in toxicity, mobility, or

volume through treatment; implementability; costs; and sustainability. The last two criteria are *modifying criteria*: state and local acceptance.

Eight remedial alternatives were developed and screened. Five remedial alternatives were selected for final evaluation according to the criteria and comparison, as follows:

- ***Alternative 1:*** No action

- ***Alternative 3:*** Excavation and off-site disposal of impacted (e.g., soil exceeding the cumulative risk level) surface and subsurface soil using conventional construction methods. Excavation and disposal of all impacted soil to a depth of two feet below soil surface meets the cumulative cancer-risk-based criterion of 1×10^{-5} and a hazard index of 1 for industrial land use. In addition, excavation and disposal of deeper impacted soil to as much as 20 feet below soil surface would meet the cumulative cancer risk-based criterion of 1×10^{-5} and a hazard index of 1 for construction workers. The residual risk analysis also identified additional removal of soil with polychlorinated biphenyl concentrations greater than 25 mg/kg in the zero to two-foot interval and with concentrations greater than 100 mg/kg in soil within the two- to 20-foot interval, to provide a margin of safety. Institutional controls would also be applied.

- ***Alternative 4:*** Excavation of impacted surface soil using conventional methods and removal of subsurface soil using large diameter augers and off-site disposal. The same locations and volumes of soil described in Alternative 3 would be excavated. Institutional controls would also be applied.

- ***Alternative 7:*** Excavation of impacted surface soil using conventional methods with off-site disposal and *in situ* thermal desorption of subsurface soil. Volumes and locations of excavated surface soil (zero to two feet below ground surface) and *in situ* thermal-desorption-treated subsurface soil (two to 20 feet below the final-design ground surface) would be the same as described in Alternative 3. Institutional controls would also be applied.

- ***Alternative 8:*** Excavation of impacted surface and subsurface soil using conventional methods and on-site *ex situ* thermal desorption. The same locations and volumes of soil described in Alternative 3 would be excavated. The excavated soil would be treated on-site, and then used on-site as backfill. Institutional controls would also be applied.

Additional common elements for the proposed Alternatives 3, 4, 7, and 8 include the following:

- removing soil piles from atop portions of the building foundation to access the complete slab

- installing a retaining wall on the western side of the building foundation to access the complete slab and to stabilize the adjacent Tilley Chemical Company property

- demolishing and on-site recycling of the Building D foundation slab and footings
- demolishing and on-site recycling of other concrete surfaces and asphalt pavement within Block E
- removing the abandoned diesel product pipeline that traverses Block E
- removing and disposing of the contaminated storm-drain system and associated contaminated soil from within Block E and through Block F to the Outfall 005 discharge locations
- designing and constructing a new stormwater-management system
- backfilling and surface restoration: placing soil, topsoil, and seed over disturbed areas
- remediating radiological impacts due to historical operations in former Building D

The alternatives were then compared to each other, both qualitatively and quantitatively, based on the balancing criteria described above (see Section 5.5).

Proposed remedial action—For Lockheed Martin Corporation, success is based on how well we recognize and fulfill our responsibilities to protect the environment, to provide a safe workplace, to protect neighboring communities, to ensure stewardship of scarce natural resources, and answer to our customers and shareholders. All of these responsibilities were considered in selecting the remedial action for Block E. This evaluation of remedial alternatives resulted in selection of Alternative 3 as the proposed remedial action for Block E soil at the Middle River Complex. The remedial actions in Alternative 3 include institutional controls to mitigate site risks, after removing up to 20 feet of impacted soil in Block E, as follows:

- all soil zero to two feet below ground surface or bottom of slab required to achieve less than cumulative human health cancer and noncancer risk levels for industrial workers, and all soil in the same interval with polychlorinated biphenyl contamination greater than 25 mg/kg, as an added safety factor
- all soil two to 20 feet below ground surface or bottom of slab required to achieve less than cumulative human health cancer and noncancer-risk levels for construction workers, and all soil in the same interval with polychlorinated biphenyl contamination greater than 100 mg/kg, as an added safety factor

In the long term, removal of impacted soil will meet all remedial action objectives. Careful sequencing of stormwater management, in conjunction with storm-drain replacement, will meet remedial action objective No. 2 during remedy performance.

A "No Further Action" letter will be sought from Maryland Department of the Environment after the soil remedial action under Alternative 3 is complete. In that letter, the Maryland Department of the Environment will establish the institutional controls and environmental covenants that will be required for Block E. For example, institutional controls will be in place to prevent inadvertent excavation or other potential exposure to contaminants that remain once remediation has been completed, as well as prohibiting the use of groundwater for any purpose. Note that, although this plan proposes industrial-health risk-based remediation, this approach would not prohibit the site from future development for residential, commercial, or recreational land uses. However, if a future use of the site is not industrial-based, additional remedial activities might be required.

Schedule—A schedule of the remedial action implementation for Block E soil is in Section 9. Major activities include:

- final remedial action plan and draft risk-based disposal approval application submittals—2019
- final risk-based disposal approval application submittal—2020
- remedial action implementation—2021
- post-remedial action monitoring—2022 through 2023

Communication and community relations—Lockheed Martin Corporation is committed to its partnership with the Middle River community and to maintaining a high level of community outreach, communication, and public engagement as remediation work progresses. Lockheed Martin Corporation will also provide remediation program updates to local civic association leadership and other civic and business organizations, and upon request will attend civic association and other meetings to provide updates, answer questions, and address issues and concerns. Lockheed Martin Corporation will also hold an information availability session before the remedial action begins to secure comment and feedback and answer questions. Lockheed Martin Corporation remains committed to two-way transparent communication with the

community to ensure that questions are answered, and that issues and concerns are addressed in a timely manner.

SECTION 1
INTRODUCTION AND SITE BACKGROUND

This section presents the purpose, scope, and organization of the remedial action plan for Block E soil, including a summary of the content of each section of the remedial action plan.

1.1 PURPOSE OF THE REMEDIAL ACTION PLAN

On behalf of Lockheed Martin Corporation (Lockheed Martin), Tetra Tech, Inc. (Tetra Tech) has prepared this remedial action plan (RAP) for Tax Block E (Block E) at the Lockheed Martin Middle River Complex (MRC) in Middle River, Maryland. The location of the Middle River Complex is shown in Figure 1-1. This remedial action plan was prepared in accordance with requirements enforced by the Maryland Department of the Environment (MDE) and overseen by its Land Restoration Program in accordance with Administrative Consent Order ACO-SAR-MDE0746-2015-1-01. Tax Block E, along with other portions of the Middle River Complex, was accepted into the Maryland Voluntary Cleanup Program in 2006, but was withdrawn from the program in 2013 so that the environmental restoration of Middle River Complex soil, groundwater, and offshore sediment could be consolidated under the consent order into a single regulatory program. Appendix A contains a copy of the withdrawal letter documenting this change. The consent order became effective in December 2015.

This remedial action plan provides the background, supporting documentation, and framework (i.e., goals, performance-evaluation criteria, schedule) for remediation of Block E soil. It details the remedial action objectives (RAOs), selection of remedial technologies, and implementation of remedial actions. The remedial actions and goals detailed herein are based on current and historical site data derived from the soil investigations described in Section 2 and the anticipated land use. This remedial action plan provides information necessary to support the decision to remove contaminated soil to achieve the following remedial action objectives:

Remedial action objective	Description
1	Reduce site-related chemicals of concern in Block E soil to not exceed a cumulative human health cancer-risk limit of 1×10^{-5} and a cumulative non-carcinogenic hazard index of one for industrial workers and construction workers.
2	Prevent transfer of polychlorinated biphenyls to the extent practicable from surface soil and storm drains to discharged stormwater at concentrations that would impact the sediment remedy.
3	Prevent to the extent practicable leaching of polychlorinated biphenyls and 1,2,4-trichlorobenzene from soil to groundwater at concentrations that would impact surface water concentrations.

Upon approval of this remedial action plan, Lockheed Martin Corporation will proceed with developing the full remedy design, obtaining permits, and submitting a risk-based disposal approval application (RBDAA) in accordance with United States Environmental Protection Agency (USEPA) regulations implementing the Toxic Substances Control Act (TSCA) in 40 CFR 761.61(c).

1.2 SCOPE

Block E consists of three recognized environmental conditions (RECs): (1) former Building D (REC #1); includes five former transformer rooms); (2) a product pipeline connecting a former fuel oil storage tank to former building (REC #2); and (3) a former 500,000-gallon fuel oil aboveground storage tank (AST) and former associated underground storage tank (REC #3). The Maryland Department of the Environment (MDE) considers sites with a cancer risk greater than 1×10^{-5} (i.e., a one-in-100,000 increased probability of cancer) or a hazard index (HI) greater than 1 as sites that require remedial action.

The *Human Health Risk Assessment (HHRA) for Blocks D, E, F, G, and H Soils* (Tetra Tech, 2012f.) concluded that industrial worker exposure to chemicals of concern in Block E surface soil and construction-worker exposure to contaminants in Block E subsurface soil would result in a cancer risk greater than the MDE threshold, indicating that remedial action is necessary to reduce health risk. Remediation in accordance with Toxic Substances Control Act requirements (risk-based disposal approval, 40 *Code of Federal Regulations* 761.61[c]) is also required, because some concentrations of polychlorinated biphenyls exceed 50 milligrams per kilogram. This remedial action plan evaluates risk-based remedial actions (based on continued industrial use of

the site) that will achieve the remedial action objectives established for Block E soil. The remedial actions for Middle River Complex groundwater are described under a separate, approved, groundwater response action plan (Tetra Tech, 2012c).

1.3 ORGANIZATION

The Block E remedial action plan for soil is organized as follows:

Section 1—Introduction and Site Background: Presents the purpose, scope, and organization of the remedial action plan.

Section 2—Middle River Complex Block E Overview: Briefly describes the Middle River Complex, site history, prior environmental investigations and results, and the conceptual site model for Block E.

Section 3—Exposure Assessment: Presents the current and potential land use at the site, and describes environmental media of concern and possible contaminant-exposure pathways.

Section 4—Cleanup Criteria: Presents remedial action objectives, chemicals of concern, preliminary remedial goals, a residual-risk analysis summary, and protocols for attainment of preliminary remedial goals.

Section 5—Remedial Action Alternative Development and Evaluation: Presents the screening of technologies and process options, the development and analysis of alternatives, a comparative analysis of alternatives, and describes the alternative proposed to clean up the soil in Block E.

Section 6—Contingency Measures for the Selected Remedial Action: Presents the contingency measures to be employed if the selected alternative does not perform as expected.

Section 7—Proposed Remedial Actions: Presents the plan for the work necessary to perform various components of the proposed remedial actions.

Section 8—Permits and Notifications: Presents the permits and approvals that will be required to implement the Maryland Department of the Environment- and United States Environmental Protection Agency-approved remedial action plan and future risk-based disposal approval application.

Section 9—Implementation Schedule: Presents the detailed schedule for all work necessary to implement the Maryland Department of the Environment- and United States Environmental Protection Agency-approved remedial action plan and future risk-based disposal approval application.

Section 10—References: Lists references and citations used in compiling this remedial action plan.

- Appendix E—Previous Investigation Data (Tables)
- Appendix F—BaPEq Calculation
- Appendix G—Block E Groundwater Depth Contour Maps and Soil PCB Isoconcentration Maps
- Appendix H—Total Cost Analysis
- Appendix I—Radiological Remediation Plan
- Appendix J—Hydrologic Modeling and Conceptual Grading
- Appendix K—*In Situ* Stabilization/Solidification Treatability Study
- Appendix L—*SiteWise*™ Information
- Appendix M—*Criterium*® *DecisionPlus*® Analysis
- Appendix N—Permit List

SECTION 2
MIDDLE RIVER COMPLEX
BLOCK E OVERVIEW

This section includes an overview of the site background and site-specific chemicals of concern (COC) in Tax Block E (Block E) at the Middle River Complex (MRC). Also summarized are the findings of previous site investigations, our understanding of the nature and extent of site contaminants, COC persistence and migration in the environment, and applicable exposure pathways, collectively known as the conceptual site model.

2.1 MIDDLE RIVER COMPLEX BACKGROUND

The MRC, located approximately 11.5 miles northeast of downtown Baltimore, is bounded by Eastern Boulevard (Route 150) to the north, Dark Head Cove to the south, Cow Pen Creek to the west, and Martin State Airport (MSA) to the east (Figure 1-1). The MRC consists of approximately 161 acres, including Tax Blocks A through I (except Block C), and is currently occupied by 12 main buildings with surrounding parking and storage areas (Figure 2-1).

The MRC is part of the Chesapeake Industrial Park at 2323 Eastern Boulevard in Middle River, Maryland. The area currently includes active industrial properties, perimeter parking lots, an athletic field, a vacant concrete-covered lot (Block E), a trailer storage lot, and numerous grassy areas along the facility perimeter, also including a former seaplane launch ramp. Locked and access-controlled chain-link fences surround the main industrial area and all external properties, including Block E. Figure 2-1 is an MRC layout map showing the active industrial facility (Tax Block I) and the external Tax Blocks A, B, D, E, F, G, and H surrounding Tax Block I. LMC Properties, Inc. (LMCPI) owns and manages the MRC, and periodically leases space to other parties for storage, parking, and various operations. Block E is one of several properties at the MRC being managed by Lockheed Martin Corporation (Lockheed Martin) as part of environmental stewardship efforts to address contamination from former industrial operations.

In 1929, the Glenn L. Martin Company (a predecessor entity of Lockheed Martin) acquired a contiguous parcel of undeveloped land in Middle River, Maryland on which to manufacture aircraft for the United States government and commercial clients. In the early 1960s, Glenn L. Martin Company merged with American-Marietta Company to form Martin Marietta Corporation. In 1995, Martin Marietta Corporation merged with Lockheed Corporation to form Lockheed Martin and focused its on-site operations at MRC on equipment construction and testing for the United States government and commercial clients. Shortly after the merger, General Electric Company acquired most of Lockheed Martin's aeronautical business in Middle River and began operations under General Electric subsidiary MRA Systems, Inc., reportedly is being sold by GE to Singapore Technologies Engineering.

2.2 BLOCK E BACKGROUND

Block E consists of two adjoining parcels, the main portion of Block E (15.433 acres) and Lot 3, identified hereinafter as "Block E2" (0.533 acre) in the southern portion of the block. Block E is bounded on the north by the active industrial portion of the complex (Block I), to the east by Parking Lot No. 6 (Block D), to the south by Waterfront Lot (Block F), and to the west by the Tilley Chemical Company (Figure 2-1). The former location of Building D encompasses approximately half of the Block E area. Building D was constructed very rapidly in the early 1940s and razed in December 1971. Demolition records indicating disposal plans, or disposal manifests for former Building D building materials, were not located. The remaining concrete floor slab, corresponding to the former basement floor, defines the current grade (Figure 2-2). The following sections summarize former industrial operations at Block E and former Building D, and describe current conditions at Block E.

2.2.1 Aircraft Assembly

Historically, the MRC facilities have been used primarily to design, develop, assemble, and test aircraft and missile launching systems. Block E, in the southern portion of the Middle River Complex, is the site of former Building D, which was demolished to the basement floor level in 1971. The building had an assembly floor (first floor) that exited at the grade of the current Tilley Chemical Company property, along with a basement level (the current concrete slab). The former building occupied approximately 400,000 square feet. Historical engineering drawings obtained

from MRC files show that the former basement areas were used for welding, extrusion milling, engine preparation, and assembly, as well as various radiological activities.

Former elevators and former heater rooms were along the northern, eastern, and southern interior perimeter of the former building, and former electrical transformer rooms were along the northern and southern interior perimeter. A cafeteria and cleaning/plating and finishing rooms were along the southern interior wall, near the center of the building. Figure 2-3 shows the historical factory layout and features of former Building D.

2.2.2 Radiological Research, Testing, and Fabrication

Historical engineering drawings indicate that the western and southwestern portion of the basement housed several nuclear-related offices, manufacturing spaces, and laboratories. The former nuclear operational areas at Building D area are shown on Figure 2-4. Historical operations of radiological significance involved the following:

- research, development, fabrication, and testing of fuel assemblies for nuclear reactors using varying enrichments of uranium-235 (U-235)
- fabrication of aircraft components, including thermoelectric generators known as Systems for Nuclear Auxiliary Power generators, using magnesium-thorium alloy (4% thorium as thorium-232 [Th-232])
- possession of sealed or plated sources, including a cobalt-60 source, thought to have been used for instrument-quality checks and radiography operations

Residual radioactive contamination remained in the underground drain lines of the vacated building in these areas of Building D before demolition. Radiological surveys, decontamination, and sampling were conducted before, during, and after demolition to address this issue.

Nuclear Regulatory Commission (NRC) records indicate that decontamination of Building D removed radioactive residue in June–September 1970 under the administration of the NRC's predecessor, the Atomic Energy Commission (AEC). The final survey report was issued September 22, 1970. The building was demolished in December 1971, about one year after the final survey report. In 1982, the NRC reviewed the post-decontamination survey and concluded the following:

"The Building D, which was decontaminated and released for unrestricted use when AEC license SNM-1192 was terminated, is the same facility where work was authorized by license Nos. C-3991, and if any material remained from operations under these licenses it would have been detected and removed during that effort.

"No determination could be made if the drains containing residual U-235 activity were sealed with cement, however, since the building is now demolished and the site covered with grass, this activity is unlikely to present a hazard.

"Region I concludes the site meets current NRC criteria for release for unrestricted use, and that no site survey is necessary."

NRC confirmatory survey—In 1995, NRC and state personnel made an announced inspection and survey of Building C and the site of former Building D at the Martin Marietta Middle River facility, and an inspection and survey of Buildings KJ and KC at MSA. The inspection was closeout verification for AEC licenses 19-01398-20, 19-01398-32, SNM-11, SNM-53, SNM-907, SNM-1192, and STB-00187. Gamma walkover surveys of the Building D concrete pad were also performed during the 1995 inspection. The inspectors surveyed the concrete pad along parallel lines five meters apart, paying attention to drains, clean-outs, and holes in the pad. In addition to measurements taken at drains and clean-outs, surface contact readings were also taken at approximately 10-meter intervals.

Numerous sealed or filled-in drains, clean-outs, penetrations, and holes in the pad were located. Although some appear to be former drains filled with concrete, it is not apparent whether any of these are the drains referred to in the closeout survey. Martin Marietta staff stated that the rubble from the building demolition had been the contractor's responsibility. It was removed and is believed to have been disposed of in a landfill. No detectable radiation levels above background (5 micro roentgens per hour [μR/hr]) were found. Although the NRC stated it had no indication that the licensee's commitment to seal five contaminated drains with concrete had been verified, the facility was nevertheless deemed suitable for unrestricted use. The NRC's 1982 and 1995 determinations that the facility was deemed suitable for unrestricted use are therefore interpreted to apply to current conditions.

2.2.3 Current Conditions—Block E

The area occupied by former Building D has not been redeveloped since the building was demolished in 1971. Portions of the area are used to store lowboy trailers and airplane carcasses

belonging to the Glenn L. Martin Aviation Museum at MSA. A shed used to store road salt and sand is in the northwestern corner of the former Building D footprint. A 500,000-gallon, aboveground storage tank (AST) and pump-house associated with the facility fire suppression system are in the southeastern corner of Block E. Tilley Chemical Company occupies the western adjoining property, and stores trailers on the concrete parking apron of former Building D in the southwestern corner of Block E.

The basement floor consists of concrete slabs with ceramic tiles overlaying the concrete in several locations (see Appendix B). Construction joints or expansion joints (with associated cracking) are between the slabs. Former sumps and floor drains associated with the building's manufacturing process, some of which have been plugged with concrete or grouted, remain within the existing concrete slab. Areas off the foundation slab are either ancillary concrete parking and access points, or are covered in grass or other vegetation.

Steep soil slopes along the western and northwestern edges of Block E represent areas where the existing grade was higher than the eastern ground surface (with elevation differences of approximately 12 feet), and the topography was lowered to provide a level surface to construct the building. In these sloped areas, the soil has slumped onto the outer edge of the foundation slab after the building removal. Throughout this remedial action plan (RAP), these soil features are referred to as "soil piles."

Environmental features associated with Block E referenced throughout this RAP include three recognized environmental conditions (RECs) identified in 2003: former Building D (REC #1) (including five former transformer rooms), the product pipeline (REC #2), and the former 500,000-gallon aboveground storage tank and associated tank (REC #3) (Earth Tech, Inc., 2003). Figure 2-4 shows historical Block E features and RECs.

The former Building D (REC #1) is presently visible as a concrete slab representing the former basement level, which exhibits joints, cracks, and areas of subsidence. Former floor drains have been filled with concrete. Five former transformer rooms were on the building slab. Due to the suspected former existence of transformers with polychlorinated biphenyl- (PCB-) containing oils, the former transformer room areas have been investigated extensively. Polychlorinated biphenyls

(PCBs) were detected at elevated concentrations in concrete and soils in REC #1, particularly around three of the former transformer rooms (Transformer Rooms 2, 3, and 4).

The product pipeline (REC #2) is a 1,815-foot-long, two-inch-diameter pipe running underground from the former 500,000-gallon fuel oil aboveground storage tank (REC #3) to the MRC power plant (in Block I). Approximately 1,500 feet of the pipeline is within Block E. The pipeline supplied fuel oil to the powerhouse. The pipeline location coincides with that of a drainage ditch running along the western and southern boundary of Block E. A small portion of the pipeline (approximately 200 linear feet) and 120 cubic yards of surrounding soil were excavated and disposed of offsite in 2002 during AST removal at REC #3 (Earth Tech, 2003). This work was performed by LMC Properties, Inc., (LMCPI) under permit and approval of the Maryland Department of the Environment (MDE) Emergency Response Program. The remainder of the pipeline (approximately 1,300 linear feet within Block E) was abandoned in place when Building D was demolished (Figure 2-4).

The former 500,000-gallon AST and associated tank (REC #3) were in a grassy shoulder in the southeastern portion of Block E near the fire pump building. The former AST was surrounded by a shallow earthen berm. A 500-gallon underground storage tank (UST) was associated with this larger tank, reportedly to collect excess oil from the pressurized lines after the AST was filled. The area associated with this tank has been the subject of separate groundwater characterizations, and is the location of a groundwater remediation system that addresses historical solvent releases thought to result from a separate UST discovered and removed in 2013 adjacent to the Building D foundation slab. The groundwater response action is in progress in this area, and is independent of the remaining Block E impacts presented in this report. The *in situ* groundwater bioremediation system wells and piping have been installed, but the system is not yet in operation. An addendum to the groundwater response action plan (Tetra Tech, 2018c), recommending an expansion of that system and installation of a groundwater containment system and permeable reactive barrier in Block F, was approved by the Maryland Department of the Environment in July 2018. Design of that system is proceeding, and installation is anticipated to be completed in late 2019.

The soil remedial action will ultimately focus on remediation of PCBs and, to a lesser extent, other chemicals, but the cleanup is significantly complicated by site physical characteristics and the historical in-place concrete capping of five floor-drain inlets with indications of radiological contamination. Remediation of the site will also include demolition of the concrete slab and tiles and remaining former Building D features, and reconfiguration of the storm drain system to accommodate post-remediation restoration.

2.3 BLOCK E PREVIOUS INVESTIGATIONS

Section 2.3 summarizes prior and current site characterizations and the remedial investigation undertaken at Block E. Several investigations have been completed since 2003 to develop a full understanding of environmental impacts to various site environmental media from past operations at Block E. Investigations related to Block E have included reviews of records, maps, and design drawings, discussions with current and former MRC personnel, geophysical surveys, geotechnical studies, physical site condition evaluations, and extensive multimedia sampling. Comprehensive sampling at Block E has included collecting 113 concrete samples, more than 1,000 surface soil samples, more than 600 subsurface soil samples, 116 groundwater samples from more than 50 monitoring wells and over 40 temporary well points, stormwater samples from more than 16 manholes and inlets, and other miscellaneous samples.

2.3.1 Block E Investigation Timeline

Previous investigations documented in reports related to Block E soil characterization include the *Phase I Environmental Site Assessment* (Earth Tech, Inc., 2003); the *Final Report Phase II Site Investigation of Exterior Areas* (Tetra Tech, 2004a); the *2004 Phase II Environmental Site Assessment* (Tetra Tech, 2005a); the *Final Data Report, Site-Wide Phase II Investigation* (Tetra Tech, 2005b); the *Phase II Soil Investigation* (Tetra Tech, 2006a); the *Site Characterization Report* (Tetra Tech, 2006b); the *Block E Supplemental Soil and Storm-Drain Sediment Characterization Report* (Tetra Tech, 2010); the *Block E Data-Summary Report* (Tetra Tech, 2011); the *Additional Block E Soil Characterization Report* (Tetra Tech, 2012a); *Blocks E and G Pre-Design Soil-Sampling Investigation Report* (Tetra Tech, 2012e); the *Supplemental Investigation: Block E and Block I, 2013 Report* (Tetra Tech, 2014c); *Block E Soil Sampling Investigation* (Tetra Tech, 2015); and the *Remedial Investigation, Block E Soil* (Tetra Tech, 2018a).

Soil characterization results from 2003 to 2017 are fully documented in the reports listed above and are not detailed herein. A timeline of the primary Block E characterization and soil remedial investigation activities and reports is presented below. The applicable data and findings from these investigations are incorporated throughout this RAP, including supporting tables and figures:

- The Block E site characterization in 2003–2005 included a risk assessment that identified PCBs as a COC (Tetra Tech, 2006a and 2006b).
- Additional Block E soil and storm-drain sediment characterization from 2007 to 2009 further delineated PCBs (Tetra Tech, 2010).
- A human health risk assessment (HHRA) was completed in 2012 (Tetra Tech, 2012f).
- Subsequent investigation in 2012 (Tetra Tech, 2012a and 2012b) included extensive sampling of concrete, surface and subsurface soil, and groundwater, and investigation of utility cross-connections.
- A soil investigation examined areas of Block E where the infrastructure of the groundwater remediation system would be placed (Tetra Tech, 2012e).
- Implementation of an MRC groundwater response action plan began in 2013 (Tetra Tech, 2012c). During system installation in Block E, two small underground storage tanks (USTs) were encountered adjacent to the southern side of Building D, one of which was co-located with a significant trichloroethene (TCE) release to the subsurface soil and groundwater. Multi-phase extraction reduced TCE concentrations in groundwater to the performance goal originally planned so that the groundwater remedy (anaerobic reductive dechlorination) could remediate any remaining TCE. A narrow TCE plume, extending from the UST to Dark Head Cove, was subsequently delineated. The groundwater response action was amended to include remediation of the extended plume, and was approved by the MDE in July 2018 (Tetra Tech, 2018c).
- Studies associated with groundwater remediation, including the *Blocks E and G Pre-Design Soil-Sampling Investigation* (Tetra Tech, 2012e) and *Summary Report for Soil and Groundwater Delineation, Block E USTs 1 and 2* (Tetra Tech, 2013a), included monitoring well sampling for PCBs and soil delineation in areas of groundwater remediation infrastructure.
- Summary reporting for two Block E monitoring wells installed downgradient of Transformer Room 2 indicate that low concentrations of lighter PCB homologs have migrated a short distance downgradient (Tetra Tech, 2018a).
- From 2016 to 2018, a remedial investigation was completed, and a report was prepared (Tetra Tech, 2018a). The RI sampling locations and depths were selected to complement prior Block E data and further delineate subsurface impacts identified as part of earlier

investigations. The risk-based cleanup goals (preliminary remediation goals [PRGs]) from the 2012 risk assessment were updated using the full set of Block E soil data, including data from 2013 to 2017.

- A residual risk analysis (RRA) (Tetra Tech, 2018d) was completed in support of this remedial action plan (RAP), incorporating all Block E soil chemical data obtained between 2003 to 2017 (see Appendix C).

- Sampling was completed in August 2018 for delineation of PCBs in the surface soils in roadway medians adjacent to Block E, along Chesapeake Park Plaza (Tetra Tech, 2019a). This sampling indicated the presence of PCBs at some locations in the center median and on the southern edge of Chesapeake Park Plaza, along Block F. Further information is in Section 4.3.3.

The complexities of Block E and its associated chemical releases have resulted in extensive environmental study. Activities associated with groundwater investigations and remediation for solvents in the southeastern corner of Block E have included sampling for PCBs, the primary chemical of concern, in both groundwater and soil. However, groundwater impacts in this area are being addressed separately from soil, along with other impacted groundwater areas of the MRC.

2.3.2 Block E Chemical Data and Comparison Criteria

Chemical data for Block E, including positive detections only for soil- and concrete-sampling results from all previous investigations (i.e., nondetect results are not listed), are in Appendix D. The chemical data for Block E soil in Appendix D are compared to the site-specific risk-based screening levels based on exposures and receptors developed in the HHRA. Surface soil is defined as zero to two feet below ground surface (bgs). ("Ground surface" and "soil surface" refer to the ground surface where the soil is exposed or the soil in contact with the bottom of the concrete where a foundation is present.) Subsurface soil is defined as from two feet bgs to the vertical limit of investigation. The chemical data for concrete, specifically PCB Aroclors, are compared to the Toxic Substance Control Act (TSCA) special handling and disposal concentration of 50 milligrams per kilogram (mg/kg) for total PCBs. Complete data tables (including nondetect results) for Block E soil, concrete, groundwater, and water from voids below the slab (i.e., sub-slab water) are in Appendix E.

During previous investigations, screening criteria used for data comparison have varied due to revisions to the Maryland Department of the Environment (MDE) cleanup standards and other

applicable criteria. Residential screening criteria were conservatively used to screen soil data in earlier reports; however, based on the current and projected use of the property, industrial soil screening criteria are more appropriate. Chemicals detected in soil at concentrations exceeding the more conservative residential screening criteria during previous investigations were evaluated further in each subsequent investigation, and those chemicals exceeding MDE residential and industrial criteria are collectively addressed as chemicals of potential concern (COPC) in this remedial investigation. A human health risk assessment was completed in 2012 (see third bullet, above), resulted in the development of site-specific, risk-based screening levels for Block E (Tetra Tech, Inc., 2012f).

The risk-based screening levels, or preliminary remediation goals (PRGs), for Block E surface and subsurface soil chemicals of concern (COC) were updated in 2017 based on revisions to some United States Environmental Protection Agency (USEPA) exposure assumptions. The updated PRGs for Block E were documented in the memorandum from Lockheed Martin Corporation (Lockheed Martin) to the Maryland Department of the Environment (MDE) titled *Technical Memorandum–Preliminary Remediation Goals for Industrial and Construction Workers; Block E Soil Remediation Lockheed Martin Corporation; Middle River Complex* (Lockheed Martin, 2018). The Block E PRGs are presented in Section 4.

Block E groundwater data are conservatively screened against surface water quality criteria developed to protect human health or ecological receptors, because Block E groundwater is likely hydraulically connected to Dark Head Cove surface water (Figures 2-2 and 2-20). Neither shallow groundwater nor surface water is used as a drinking water source on or near the MRC. Lockheed Martin anticipates that groundwater use restrictions, as well as soil management and notification protocols, will be imposed by the MDE to secure site closure under a "No Further Action" letter.

2.4 CONCEPTUAL SITE MODEL

This section summarizes the conceptual site model (CSM) developed for Block E soil based on current conditions at the site, and the results of previous investigations, as summarized below and in Section 4.2.

2.4.1 Contaminant Sources and Chemicals of Concern

The human health risk assessment (HHRA; Tetra Tech, 2012f) and residual risk analysis (Tetra Tech, 2018d) identified PCBs (e.g., Aroclor 1254, Aroclor 1260), polycyclic aromatic hydrocarbons (PAHs, expressed as benzo(a)pyrene equivalents [BaPEq]) (see Appendix F), TCE, and 1,2,4-trichlorobenzene (1,2,4-TCB) as COC for Block E soil, assuming typical exposures to industrial and construction workers are the receptors of concern. PCBs and, to a lesser extent, BaPEq, are the COC for the industrial worker exposure scenario, based on direct-contact exposure with Block E soil at depths of zero to two feet below ground surface (bgs).

During the update of the residual-risk analysis (RRA) for the RI (refer to Section 4.4 of this RAP and Appendix C), TCE was included in the list of COC for the construction worker scenario, due to its high detected concentrations in Block E soil in the southeastern area of the site during the UST removal and delineation (Tetra Tech, 2014a). The chemical 1,2,4-TCB was included on the COC list based on industrial worker direct contact with subsurface soil, and because it was included as an overall COC for industrial workers in the "Remedial Goal Options" section of the HHRA. However, 1,2,4-TCB does not contribute significantly to the risk estimated for the industrial worker with direct contact to surface soil. However, these 1,2,4-TCB concentrations are co-located with significant PCB source contamination in both surface and subsurface soil, so remediation of PCB will also mitigate the risk from 1,2,4-TCB. The southeastern area of the site has the highest detected concentrations of PCB Aroclor 1254.

Soil data collected from RECs #1 (former Building D), #2, and #3 in Block E indicate that past activities have released contaminants (e.g., PCBs and chlorinated benzenes, total petroleum hydrocarbons [TPH], diesel-range organics [DRO], and TCE) to the surrounding environment. The contamination beneath and around former Transformer Rooms 2, 3, and 4 (shown on Figure 2-4) appears to have resulted from release of insulating fluids from underground electric lines that tied into the former transformer rooms, or possibly from direct releases from the transformers themselves. Figures 2-5 through 2-9 show locations of all soil samples collected at Block E, and are provided for discussion of contaminant sources, and as a reference for sampling data provided in Appendices D and E. Figures showing concentrations of Block E COC in soil will be presented and discussed in Section 4.

The combined PCB data show four areas where PCB concentrations exceed screening levels (PRGs), including the three former transformer rooms and an area around an existing 500,000-gallon water tank (Figure 2-4). The first area of PCB (Aroclor 1260) exceedances is the northwestern quadrant of Block E, and includes former Transformer Room 2. Aroclor 1260 exceedances in this area are primarily in subsurface soil ranging from two to 20 feet bgs. The highest Aroclor 1260 concentration (two orders of magnitude above PRG) in this area was at a depth of 6-8 feet bgs, just south of the Transformer Room 2 footprint (E-SB-1499; see Figure 2-5).

The second area of PCB (Aroclor 1260) exceedances is in the southwestern portion of Block E, near the former nuclear laboratory, former electrical Transformer Room 4, and the former waste collection area (Figure 2-3). In borings near former Transformer Room 4, PCBs were detected in subsurface soil at levels more than two orders of magnitude above PRGs, and in soil up to 12 feet bgs (e.g., at locations E-SB-1551 and E-SB-1598; Figure 2-7). Results from several deep-soil borings advanced in this area indicate that elevated PCB concentrations are in deep soil up to 20 feet below grade in the southwestern portion of Block E (e.g., E-SB-1471 and E-SB-1476; Figure 2-7).

Product in the form of nonaqueous-phase liquid was observed trapped in the soil matrix nine feet below the soil surface at sampling location E-SB-833, located approximately 15 feet north of former Transformer Room 4. Product was not observed in the surrounding boreholes and at sampling locations in this area, although elevated concentrations were detected as deep as 20 feet below grade.

The maximum depth PCB exceedance in the southwestern area is 20 feet below grade, as described above; however, results from surrounding deep-soil borings indicate that the lateral extent of PCB exceedances at this depth is limited. Exceedances in surrounding borings are only in soil samples collected from 18 feet bgs or less, with most detected less than 12 feet bgs.

The third area of PCB (Aroclor 1260) exceedances is in the south–central area of former Building D (e.g., the southern quadrant; see Figure 2-8). This area housed the former cleaning, plating, and finishing rooms (first floor); former electrical Transformer Room 3 on the basement

floor; and an electrical substation outside the building (basement features shown on Figure 2-3). Elevated Aroclor 1260 concentrations in this area are generally within 30 feet of former Transformer Room 3. Most PCB exceedances are limited to the first eight feet of soil. However, PCB exceedances have been detected in soil 16 to 18 feet deep at two borings in this area (i.e., at locations E-SB-1590 and E-SB-1736; Figure 2-8). PCBs here likely resulted from release of insulating fluids from underground electric lines that tied into the former transformer room, or possibly resulted from direct releases from the transformers during operations or during building demolition. Likewise, these release mechanisms were likely applicable in Transformer Rooms 1, 2, and 4.

The grassy field west of the water tank is the fourth area of PCB exceedances, the former site of a 500,000-gallon diesel fuel oil AST (Figure 2-3). Elevated Aroclor 1254 concentrations are unique to soil in this area; Aroclor 1260 is the predominant PCB in other areas of the site. The deepest exceedance of PRGs in this area is at seven feet bgs (E-SB-1375, Aroclor 1254 was detected at 6-7 feet bgs; Figure 2-9). The origin of PCBs (including Aroclor 1254) in this area is unknown, but might be indicative of spills with a different formulation of dielectric fluid, or might be due to some other PCB-containing oil used during historical facility operations. Elevated TCE concentrations also occur in soil at the southeastern portion of Block E, as indicated in soil data collected during the 2013 installation of the groundwater treatment system wells and piping, and during the UST delineation. Elevated TCE concentrations were delineated vertically to 12 feet below soil surface. These high TCE concentrations are likely associated with leaks from the former UST discovered and removed in this area. The groundwater response action to address the chlorinated solvents in the southeastern portion of Block E is in progress (see Section 2.2.3).

2.4.2 Geology

The interpretation of subsurface conditions at the Middle River Complex is based on observations made during installation of soil borings and temporary and permanent groundwater monitoring wells during the numerous site investigation/characterization efforts conducted since 2003 (see Section 2.3 for a summary of previous investigations). Before construction of Building D, the Block E area was a wetland or low-elevation uplands associated with Dark Head Cove (see historical shoreline shown on Figure 2-4). The area was filled with varying depths of soil to expand

the usable area of the MRC and construct Building D and the Dark Head Cove sea plane ramp and bulkhead area to the south. Logging of classification and description of soil beneath the MRC, and specifically in Block E (conducted during extensive site characterization), have identified a very heterogeneous substrate. Underlying soil is composed primarily of silty sands, fine- to medium-grained sands, silty clays, clayey silts, and plastic clay, with the primary lithologies being clay to silty clay and silty sand.

In most areas across the site, either sand or clay to silty clays dominates the subsurface, and form large, continuous thicknesses. In other portions of the site (especially the southwestern former Building D footprint), discontinuous layers of sand and clay to silty clay dominate the subsurface. Sand lenses (generally defined as thicknesses less than five feet) were encountered, but generally do not appear to be continuous in this area. Geologic cross-section figures, developed using interpretations of geologic conditions from all Block E environmental subsurface borings, are shown on Figures 2-10 through 2-18. These cross sections also depict construction details of borings and wells and total Aroclor concentrations. Figure 2-10 shows the location of each of the cross sections in the Block E area.

In the area north of the former Building D footprint, clay and silty clay are the predominant subsurface lithology, with minor amounts of sands observed (likely not interconnected or continuous). From approximately the northern extent of the former Building D footprint and extending to the south, a sand unit dominantly occurs. The thickness of the sand unit varies from less than five feet to 20 feet thick, with its greatest thicknesses occurring near the central portion of the former Building D footprint (see Figure 2-11 [MRC-MW-123 and MRC-MW-124]). Clay and silty clay underlie the sand unit.

In the western portion of the former Building D footprint, the subsurface is dominantly clay and silty clays with minor sand layers (less than five feet thick) throughout the upper 30 feet. From the central portion to the eastern extent of the former Building D footprint, much of the upper 10 feet of the subsurface contains various surface materials (concrete, asphalt, etc.). Underlying this disturbed material is typically clay and silty clays, though a laterally extensive sand layer (up to 20-feet-thick) occurs in the central portion of the site. A sand layer more than 10-feet-thick occurs

below the clay and silty clay in the eastern portion of the site, with a massive clay layer at approximately 30 feet bgs and minor sand layers also occurring within the clay and silty clay.

Boring logs for wells installed in the western portion of the former Building D footprint (wells MRC-MW-43A and MRC-MW-44A) indicate six to 11 feet of sandy silt and silt underlain by one to three feet of clay. The clay is underlain by additional silt and sandy silt down to 40 feet bgs. In another western well boring (MRC-MW-62C), 10 feet of silty clay is observed beneath the concrete slab, followed by 13 feet of silty sand and silt to a depth of 23 feet bgs. Two feet of clay are encountered at depths of 23–25 feet, followed by silt and fine sand to 65 feet bgs. This supports the overall heterogeneous layering of various thicknesses of clay, silt, and sand units across the former Building D footprint (and Block E area).

In the eastern portion of the former Building D footprint (well MRC-MW-34C), 25 feet of sand and silty sand are directly beneath the basement slab. A four-foot thick clay layer is present from 26 to 30 feet bgs, followed by silt and fine sand to a depth of 62 feet bgs. The log from a deep well (MRC-MW-96D) installed south of the concrete slab of the former Building D footprint indicates 52 feet of dense clay at depths of 65–117 feet bgs near Dark Head Cove. The 52-feet-thick clay layer is expected to be at depths of approximately 70–122 feet below grade at the concrete slab area, because the concrete slab is approximately five feet higher than where deep well MRC-MW-96D is located.

The subsurface depiction of soil types from the cross-section interpretations and other individual well logs across the former Building D footprint (and Block E area in general) can be described as clay and silty clay and sands, usually with one of these lithologies dominating an area. Generally, sand interbedded with clay and silty clays is observed in the upper 20 feet of subsurface throughout the central to eastern portion of the former Building D footprint, underlain by clay and silty clay. Clay and silty clay with minor sand lenses occur in the western to central portion of the former Building D footprint. Along the southern extent of the former Building D footprint, clay and silty clay occur with multiple thin sand lenses. The history of the property, and the nature of its location and its historical use, suggest that there might be greater fill thicknesses near Dark Head Cove that thins toward the Block E area. The use of fill was prevalent at MRC in the 1940s when the former Building D and the Dark Head Cove bulkhead were constructed.

2.4.3 Hydrogeology

Groundwater in the Block E area is generally shallow, ranging from a few feet to approximately 15 feet bgs. The subsurface geology is typically composed of clay and silty clay and sands, usually with one of these lithologies dominating an area. Generally, sand interbedded with clay and silty clays is observed in the upper 20 feet of subsurface throughout the central to eastern portion of the former Building D footprint, underlain by clay and silty clay. Clay and silty clay with minor sand lenses occur in the western to central portion of the former Building D footprint. Groundwater occurs within the sand portions of the upper aquifer. Groundwater typically occurs under semi-confined conditions within a few feet to approximately 15 feet below ground surface.

The shallow, or surficial, groundwater system is divided into an upper and lower zone, though in many locations across the Block E area, no clear distinction exists between these zones. Generally, wells screened in the upper surficial zone have well screens as deep as 21 feet bgs, and wells in the lower surficial zone are screened as much as 10 feet below the upper surficial zone well screens (most are screened approximately five feet below the upper shallow well screens). The upper and lower zones are separated by clay and silty clay in some areas of the site.

A synoptic round of water levels was collected at the Block E area on January 9, 2019. Block E groundwater monitoring wells are shown on Figure 2-19. Groundwater elevations were determined in feet according to the North American Vertical Datum (NAVD), based on measuring point elevations and measured depth to water for each well. Groundwater elevations were posted on site maps to determine the upper and lower surficial groundwater-flow directions and gradients. For reference, the elevation of the top of the concrete slab (former Building D footprint) is approximately 11 feet NAVD. Potentiometric surface maps for the upper and lower surficial-groundwater zones are in Appendix G.

Groundwater flow in the upper surficial-groundwater zone is to the southeast, toward Dark Head Cove. Groundwater flow in the deeper (lower surficial) zone is also southeast toward Dark Head Cove. Minor variations in the groundwater flow-field occur in the north-central portion of Block E (near MRC-MW124), resulting in localized groundwater flow in a more southerly and easterly direction. However, overall groundwater flow is still ultimately southeast. No surface water bodies cross or emanate from Block E, and no wetlands have been identified in or around Block E.

In both the upper and lower surficial-groundwater zones, the hydraulic gradient is more subdued (less) across the Block E area, as compared with the area between Block E and Dark Head Cove in Block F. This is likely due to the concrete slab, which limits infiltration of rainfall through this area (although there are significant voids under the southern portion of the foundation slab that tend to fill with rain and create a source of water for infiltration). The horizontal hydraulic conductivities are similar for the upper and lower shallow-groundwater zones, and are estimated as 0.0094 feet/foot in the upper shallow zone and 0.011 feet/foot in the lower shallow zone.

Analysis of the depth to groundwater data from the March 16, 2018 synoptic round suggests that vertical hydraulic gradients are dominantly downward across Block E. Well clusters in the southern portions of Block E exhibit the largest downward gradients (MRC-MW103, MRC-MW125, MRC-MW126, MRC-MW128, and MRC-MW130). An upward gradient occurs at the well cluster MRC-MW37, which is adjacent to Dark Head Cove and southeast of the southeastern sub-area of Block E.

Surface runoff discharges from the site via storm drains, except for areas immediately adjacent to Cow Pen Creek and Dark Head Cove. In February 2019, MDE granted a No Exposure Certification for the stormwater, so the Maryland National Pollutant Discharge Elimination System (NPDES) permit (state discharge permit No. 06DP0298, NPDES No. MD0002852) for industrial stormwater is no longer needed and was terminated by the MDE.

2.4.4 Contaminants in Groundwater

Chlorobenzenes detected in Block E soil are also present in groundwater, around and downgradient of former Transformer Rooms 2, 3, and 4. Groundwater in the southeastern portion of Block E is contaminated with chlorinated volatile organic compounds (cVOCs), primarily TCE. These elevated TCE concentrations are attributed to leaks from a former UST removed from this area in 2013. Groundwater impacts and remediation in this area is being addressed in the most recent addendum to the groundwater response action plan (Tetra Tech, 2018c). Another TCE plume that originates in the north from the Building C area in Block I passes through the center of Block E and moves toward the southeastern area. The TCE concentrations under the former Building D foundation are much lower than those in the southeastern area (AECOM, 2018). This plume will continue to be monitored under the current groundwater monitoring program.

Groundwater PCB detections are limited to the area where elevated PCB concentrations are in soil. In general, PCBs are thought to be relatively immobile in water. Detections of PCB in unfiltered groundwater samples (but not in filtered groundwater samples) collected in 2014 indicate that soil particles (i.e., colloids) might be why PCBs are found in groundwater samples, or why facilitated transport (along with chlorobenzenes) might be occurring. Downgradient well data indicate only very limited PCB migration away from the transformer room areas. Chlorobenzenes have migrated farther than PCBs.

2.4.5 Land Use Scenario

The current and future land use scenario at Block E is considered Tier 3 ("Industrial") under MDE regulations. Under the industrial land use scenario, current and future construction and industrial workers are potential receptors.

2.4.6 Summary of Conceptual Site Model

This section provides a comprehensive summary of how the predominant site COC contribute to the Block E CSM.

Polychlorinated Biphenyls and Chlorinated Benzenes

Polychlorinated biphenyls and chlorinated benzenes appear to have been released to the environment in Block E in the following ways:

- Light surface contamination within the footprint of former Building D likely resulted from small releases associated with historical industrial operations and minimal surface infiltration via washing of industrial surfaces and introduction to shallow soil through cracks or seams in concrete and storm drains.
- Elevated contaminant levels in soil below and former Building D, from the surface to approximately 20 feet below soil surface, are likely the result of release(s) from transformers or underground insulated electrical utility lines, possibly during operation or during Building D demolition.
- The presence of Aroclor 1254 in the southeastern portion of the site does not have an identified release mechanism.

- PCBs in storm drains and drainage swales are spatially related to the elevated concentrations found in surface and subsurface soil impacted by the former transformer rooms. Extensive demolition debris (e.g., bricks) is in the pipes of the storm drain system on the southern side of the building. This debris is currently impeding flow through the system.

- Chlorinated benzene detections are in areas at or near former Transformer Rooms 2, 3, and 4. Elevated 1,2,4-TCB concentrations in soil were co-located with high concentrations of PCBs (Aroclor 1260) in soil. Chlorinated benzenes are a common constituent of PCB-based dielectric fluid (used in transformers, capacitors, and switchgear). During characterization efforts, nonaqueous-phase product (e.g., transformer oil) was observed in soil boring E-SB-833, located in the southwest quadrant of Block E and at Transformer Room 4. This discovery led to extensive further delineation of chlorinated benzene in soil and groundwater in this area.

Impacts of PCBs and chlorinated benzenes appear to be as follows:

- Aroclor 1260 is primarily detected in surface and subsurface soil below and surrounding the former Transformer Rooms 2, 3, and 4.

- Aroclor 1254 impacts are limited to surface and subsurface soil (less than seven feet bgs) in the southeastern portion of Block E, near the former 500,000-gallon diesel fuel oil AST.

- PCBs and chlorinated benzenes appear to be limited in vertical migration due to the relatively low mobility of PCBs, and due to clay and silty clay soil present throughout most of Block E, beginning at depths between four and 11 feet bgs. An exception is in the eastern portion of Block E, where silty sand was observed from ground surface to 25 feet bgs, and where TCE (but not PCBs) have been detected at depth.

- Migration of PCBs off Block E appears to be limited to sediment transport through the stormwater-system and into Dark Head Cove (see Figure 2-2). An interim remedial measure (IRM) in 2011 removed contaminated sediment from the storm drains and protected drain inlets from sediment carried by stormwater (Tetra Tech, 2012d). The interim sediment remedial action (in 2014–2015) removed PCB-contaminated sediment from the lower portions of the Outfall 005 system, from the southern Block E boundary to the outfalls in Dark Head Cove (Figure 2-2). Portions of the Outfall 006 and 008 systems (Figure 2-2) were cleaned in 2016 as part of the full sediment remedy for Cow Pen Creek and Dark Head Cove (Tetra Tech, 2013b). The Outfall 005 system was plugged near Block E in 2015 to prevent any further migration of PCB-impacted storm drain system sediment to Dark Head Cove (Tetra Tech, 2016).

- Groundwater sampling using Method 680 for PCB homologs detected very low concentrations of lower chlorinated biphenyls near the source areas (Transformer Rooms 2, 3, and 4), and trace concentrations of monochlorinated biphenyls were detected in a downgradient well. However, wells farther downgradient did not contain detectable PCB

concentrations, supporting the conclusion that PCBs are largely insoluble, and that PCB migration at Block E is arrested well before any groundwater is discharged to surface water.

- Chlorinated benzenes associated with the Block E transformer room source areas appear to have been released to soil, and have greater mobility than PCBs, and have been detected in Block E groundwater. Chlorobenzenes have migrated with groundwater downgradient of Block E, and potentially beyond the southern property boundary of Block E. Characterization of chlorobenzenes in groundwater is concurrent with this RAP, and will be addressed under a separate groundwater assessment.

Polycyclic Aromatic Hydrocarbons

PAH contamination appear to be randomly distributed in Block E soil, and is possibly consistent with historical air deposition or the potential use of urban fill during property development. Groundwater does not exhibit impacts due to PAHs; PAH contamination at Block E is limited to soil.

Total Petroleum Hydrocarbons

Total petroleum hydrocarbons (TPH-DRO) were detected in only a few samples, and were typically co-located with PCB Aroclor 1260 detections. TPH-DRO has not been detected in soil samples from other Block E areas.

Trichloroethene

The volatile compound TCE appears to have been released to the environment via historical leakage from a UST discovered in 2013, which was located along the building foundation in the southeastern portion of the site. High TCE concentrations were detected in soil in the southeastern portion of Block E, and in Block E groundwater in the southeast. A significant TCE mass in Block E groundwater was removed via a multi-phase extraction system. Enhanced bioremediation system wells and piping have been installed, and a hydraulic containment system and a permeable reactive barrier are currently in design as part of the groundwater response action plan (Tetra Tech, 2018c). Another TCE plume that originates in the north from the Building C area in Block I passes through the center of Block E and towards the southeastern area. The TCE concentrations under the former Building D foundation are much lower than those in the southeastern area (AECOM, 2018). This plume will continue to be monitored under the current groundwater monitoring program.

SECTION 3
EXPOSURE ASSESSMENT

The exposure assessment for Block E of the Middle River Complex (MRC) evaluates the risks that chemicals of concern (COC) pose to potentially exposed human populations, based on current and future land use. The exposure assessment helps guide the development of remedial action objectives (RAOs) that must be attained to meet regulations governing industrial closure for Block E soil.

3.1 CURRENT AND FUTURE LAND USE

The current Block E land use scenario is considered industrial under Maryland Department of the Environment (MDE) criteria, and land use is anticipated to remain industrial into the foreseeable future. Under the industrial land use scenario, current and future industrial and construction workers are considered potential receptors.

3.2 POTENTIAL EXPOSURE PATHWAYS

The 2012 human health risk assessment (HHRA) for Block E soil evaluated possible complete exposure pathways, including direct exposure (dermal contact, inhalation, ingestion) to site soil by current and future industrial workers, construction workers, commercial land use receptors, recreational users, and hypothetical future residents (Tetra Tech, 2012f). The objective of this remedial action plan (RAP) is to achieve a residual cancer-risk level of no greater than 1×10^{-5} (i.e., a one-in-100,000 probability) and hazard index of no greater than 1 for current industrial workers and future construction workers exposed to COC in Block E soil through dermal contact, inhalation, and ingestion. These exposure pathways are consistent with the current and anticipated future industrial land use of the site. Additionally, the current storm-drain system has been identified as a possible complete exposure pathway for recreational users due to impacted Block E soil containing polychlorinated biphenyls (PCBs) migrating through the system and into Dark Head Cove sediment. The HHRA also calculated COC preliminary remedial goals (PRGs) for the industrial and construction worker scenarios. Each PRG was set at a 1×10^{-5} risk level or at a hazard

index of 1, whichever associated risk value was lower; these risk-based values will be used as guidelines for site cleanup.

An ecological risk assessment was not completed for Block E because it has been intensely developed by industry. Much of the land surface is currently paved, leaving little available habitat. Current flora and fauna populations are those typical to industrial areas, and the site poses minimal potential risk to these populations.

The goal of the selected remedial action is to effectively reduce risks to acceptable levels according to federal and state regulations, as applicable, for industrial land-use exposure pathways. This is appropriate, because the current site use is industrial, and it is planned to remain so in the future. Institutional controls will be required to mitigate the risk associated with non-industrial-use exposure pathways. Institutional controls might include, but may not be limited to, prohibiting groundwater use, imposing soil and groundwater handling requirements, and potential restrictions for future use of the property. Institutional controls will be determined by MDE. The documentation of residual contamination is necessary to prevent known exposures during Block E utility maintenance, new utility installation, and future development, even if such development complies with the site's future industrial use plans. The following sections detail the potential transport pathways of COC in Block E soil.

3.2.1 Potential Contaminant-Release Mechanisms and Transport Pathways

The primary contaminant sources for impacts to Block E soils are the Recognized Environmental Conditions (RECs) introduced in Section 2.2.3. Chemicals can migrate within an environmental medium (e.g., soil or water) or migrate to another environmental medium (e.g., air or surface water) once released. Contaminants in surface soil could migrate to air through wind erosion or through volatile emissions. This section discusses possible contaminant release mechanisms and transport pathways for soil at Block E.

Some contaminated surface soil at Block E is beneath the concrete foundation slab, and thus not exposed to wind erosion. However, some surface soil contamination is in areas currently covered by grass and is subject to volatilization, although this is not likely a significant migration pathway. Subsurface soil is not currently exposed at the site; however, if future construction were to bring

subsurface soil (or surface soil under the slab) to the surface, contaminants in subsurface soil could be transported into the air through wind erosion or through volatile emissions. Surface soil contaminants could also be transported to surface water bodies (e.g., Dark Head Cove) through overland runoff and erosion.

Rainwater at Block E washes over exposed surface soil and into the storm drain system. Contaminants could be mobilized via particulate transport through erosion of impacted surface soil. Under current conditions, surface soil contaminants in Block E are not expected to be transported directly to surface water bodies (i.e., Dark Head Cove) through overland runoff and erosion, because the site is mostly covered by concrete pavement, and any open spaces are stabilized with maintained grass surfaces. These conditions, coupled with low topographic relief, are more favorable to infiltration and evapotranspiration rather than direct transport of COC from soil to Dark Head Cove.

A network of multiple storm-drain inlets and the drainage system at Block E discharge stormwater to Dark Head Cove via outfalls. Elevated PCB levels have been found in Block E storm drains and related stormwater outfall areas, presumably due to historical soil transport along the drainage channels and infiltration of contaminated soil bedding through joints and cracked piping in the storm drain system. Therefore, contaminant transport from soil to surface water could potentially occur, although this is no longer possible for Outfall 005 due to the placement of a permanent plug in that section of the system (Tetra Tech, 2016). Erosion from natural processes may cause overland surface soil migration to drainage swales (and storm drain inlets within swales). The Block E soil remedy must address this possible transport pathway and prevent to the extent practicable potential release of PCBs to surface water.

At Block E, PCB-impacted soil appears to have traversed through the storm-drain system and been released to Dark Head Cove. The storm-drain interim remedial action (IRM) at Block E discussed in Section 2.4.6.1 was completed in autumn 2011. The Block E storm-drain system remained active following the IRM, and it was sampled in 2013 to determine if the system is acting as a continuing source and migration pathway for contaminated sediment to enter the cove after remediation. Elevated PCB concentrations were detected in Block E storm-drain sediment during the 2013 investigation (Tetra Tech, 2015), so the storm-drain system remains a potential transport

pathway despite the IRM and an additional storm-drain cleanout completed in 2014 as part of the Dark Head Cove sediment-removal action (SRA). The presence of and subsequent cleanup of PCB-impacted sediment around the Outfall 005 discharge to Dark Head Cove led to that outfall being permanently plugged in 2015 to eliminate this transport pathway. Stormwater still moves through the system and discharges at Outfall 008, but this pathway is being monitored until the full soil remedy is implemented, and cleanout of drains is prescribed if elevated concentrations are found.

Contaminants can also migrate from both surface and subsurface soil to groundwater through leaching of chemicals in the soil. Elevated PCB concentrations have been detected in soil at depths of eight to 20 feet below soil surface (bgs) within the saturated zone. Historically, PCBs (measured as Aroclors) have not been consistently detected in Block E groundwater; however, PCBs (measured as homologs) have been detected in five monitoring wells near elevated PCB soil concentrations in Block E.

In areas hydraulically downgradient from the transformer rooms, PCBs were detected in monitoring wells in 2017, but contamination was limited to only the wells closest to these source areas. This indicates that migration of a significant mass of PCBs in groundwater toward Dark Head Cove is not occurring. Site groundwater is currently not used and, with the anticipated application of MDE-approved institutional controls after remediation, will not be used for any purpose in the future.

Although data indicate that lateral migration of PCBs at Block E is limited, and PCBs are not significantly mobile in groundwater, the conceptual site model suggests some downward (vertical) migration of PCBs at the source areas. Chemicals released from underground storage tanks (USTs) can migrate directly to groundwater (if the tank is situated, at least partly, below the groundwater table), or can leach from soil impacted by such releases, and impact downgradient groundwater and surface waters. In contrast, PCBs are not easily leached from soil or readily transported in groundwater. However, volatile organic compounds (VOCs) such as trichloroethene (TCE) and 1,2,4-trichlorobenzene (1,2,4-TCB), are considerably more soluble and mobile in groundwater, and might ultimately be discharged to surface water. The VOC 1,2,4-TCB is a common additive

in PCB-containing transformer oil. Elevated 1,2,4-TCB concentrations in subsurface soil are co-located with elevated PCB concentrations.

Volatile compounds (e.g., VOCs) can easily migrate from soil or groundwater to air. Both TCE and 1,2,4-TCB have been detected in groundwater underlying the MRC. Volatile compounds (primarily TCE) have migrated in a narrow plume from a former UST at the southeastern end of Building D to Dark Head Cove. An addendum to address this plume has been incorporated into the groundwater response action (Tetra Tech, 2018c) and been approved by MDE; the design of the groundwater remedy in this area is proceeding.

3.2.2 Fate and Transport of Site Chemicals of Concern in Soil

This section describes the environmental fate and behavior of COC in Block E soil.

Polychlorinated Biphenyls (PCBs)

The chemical groupings comprising PCBs are generally complex mixtures of individual biphenyl isomers, each consisting of two joined benzene rings and 1 to 10 chlorine atoms (mono- to decachlorobiphenyl homolog groups). As many as 209 distinct PCB compounds (known as congeners) exist, grouped into 10 homolog groups. Historically, PCBs were produced commercially in the United States from no later than 1929 until 1977 and marketed under several trade names, the most common of which is Aroclor. They were used in a wide variety of applications in many industries, including dielectric fluids in capacitors and transformers, heat-transfer fluids, hydraulic fluids, lubricating and cutting oils, and as additives in pesticides, paints, copying paper, carbonless copy-paper, adhesives, sealants, and plastics. Legislation has prohibited virtually all uses of PCBs, and their manufacture has been banned in the United States since 1979 (Eisler, 2000).

Aroclors are the most common commercial mixtures of PCB congeners. When an Aroclor (or other commercial PCB mixture) is subjected to industrial uses and/or released into the environment, the PCBs within that Aroclor transform or degrade through thermal, chemical, and/or biological processes. As PCBs are mixtures, the component congeners partition through and into different environmental media at different rates in a process known as weathering.

As weathering occurs, substantial changes in the congener ratios also occur, and the chromatographic fingerprint for the original Aroclor becomes increasingly obscured. This makes laboratory quantitation problematic, resulting in environmental samples with detected PCB concentrations that vary depending on the measurement techniques used and the standard types used for calibration. In laboratory analysis, PCB concentrations can vary according to the oven-drying technique used.

PCBs are very persistent in the environment, with a great affinity for soil particulates and organic matter in soil. They adsorb strongly to soil and sediment particles, and adsorption generally increases with the degree of PCB chlorination. Higher-chlorinated congeners are more likely to sorb, and lower-chlorinated congeners are relatively more likely to volatilize or dissolve in water. If erosion takes place, PCBs in contaminated surface soil can be mobilized via particulate transport.

The dominant PCB source to surface waters is via atmospheric deposition; however, re-dissolution of sediment-bound PCBs can also account for water concentrations. The adsorption of dissolved PCBs onto solids (e.g., suspended particulates and sediment) is greatest for solids composed primarily of organic matter and clay (USEPA, 1985). In water, PCBs are transported by diffusion and currents. Higher-chlorinated PCBs are removed from the water column by sorption to suspended solids and sediment, and can then become concentrated in biota; therefore, PCBs are persistent in the environment. Factors determining PCB biodegradability include the degree of chlorination and concentration, temperature, and the available nutrients and types of microbial population in the contaminated medium (ATSDR, 1989). Biodegradation of higher-chlorinated PCBs (such as Aroclors 1254 and 1260) occurs very slowly (HSDB, 2005).

Trichloroethene

The most prevalent industrial-scale use of TCE historically has been for vapor degreasing of metal parts (e.g., in the automotive and metals manufacturing industries). The TCE detected at Block E appears to be related to its historical storage in a UST. The actual use of the solvent has not been determined, but when Building D was an active aircraft factory decades ago, TCE could have had multiple uses in metal machining and cleaning. As a general solvent, TCE has been used in a variety of industries for decades as a component of adhesives, lubricants, paints, varnishes, paint

strippers, pesticides, and metal cleaners (ATSDR, 2014b). Also, TCE is an intermediary in the production of modern, non-chlorofluorocarbon (or non-ozone-depleting) refrigerants, the hydrofluorocarbon gases. Hydrofluorocarbons can be prepared from TCE or tetrachloroethene through halogen exchange and hydrofluorination, in which the chlorine is replaced by hydrogen and fluorine.

Once released to permeable soil, TCE is highly mobile, and diffusion from TCE-contaminated groundwater or its direct transport as a dissolved chemical in groundwater could play a role in its transport. In the subsurface, TCE can be sorbed to soil, particularly in vadose soil, where TCE does not compete with water for polar sorption sites on soil particles or organic content. Since TCE is a dense nonaqueous-phase liquid, with sufficient volume it can move through the unsaturated zone into the saturated zone, where it displaces soil pore water.

The most important routes of TCE exposure for most members of the general population are inhalation of the compound in ambient air and ingestion via drinking water. In a process known as vapor intrusion, TCE can evaporate from contaminated groundwater and soil and migrate into air spaces beneath buildings to enter the indoor air (ATSDR, 2014b). With respect to Block E, TCE is primarily a groundwater issue, and is currently being remediated under the groundwater response action. Although TCE is in soil, it is primarily present in saturated soil areas that will be addressed by the groundwater response action (Tetra Tech, 2018c). The groundwater response design will include sampling saturated soil in Block E to determine the remedy's effectiveness in reducing soil TCE concentrations. Thus, TCE is considered independent of the other COC in Block E.

1,2,4-Trichlorobenzene

Trichlorobenzenes can be released to the environment from their production and use as solvents or chemical stabilizers. At Block E, the trichlorobenzene 1,2,4-TCB is generally co-located with PCBs, and was likely used in the insulating fluid in transformers and underground electric lines. Chlorobenzenes at Block E are in soil and groundwater matrices, around and downgradient of former Transformer Rooms 2, 3, and 4. Published literature (ATSDR, 2014a) indicates that chlorobenzenes have historically been used in dielectric fluids. Chlorobenzene-containing capacitors were manufactured in the United States from 1929 to 1979, and were made in several sizes that contained from 3 to 3,000 gallons of liquid, with an average 235 gallons of liquid.

Trichlorobenzenes have been detected in surface water, groundwater, and drinking water sources near hazardous waste sites or industrialized areas that produce chlorinated substances (ATSDR, 2014a). Whether levels detected in environmental samples arise from the direct release of trichlorobenzenes, or their unintentional formation from other processes (e.g., degradation of the pesticide lindane has also been demonstrated elsewhere to result in the formation of 1,2,4-TCB), is often difficult to determine. Trichlorobenzenes volatilize from water surfaces; however, they also tend to adsorb to suspended solids in the water column and partition to sediment, which attenuates the rate at which volatilization occurs (ATSDR, 2014a).

The rate of 1,2,4-TCB hydrolysis and biodegradation is generally slow under typical subsurface conditions. Trichlorobenzenes have low mobility in soil and typically do not leach into groundwater unless a significant source in contaminated soil exists, such as appears to be present in Block E. Volatilization is expected to be an important environmental fate process for trichlorobenzenes released to soil; however, adsorption can reduce the rate at which trichlorobenzenes evaporate from soil surfaces. Trichlorobenzenes biodegrade slowly in soil under aerobic conditions, but undergo reductive dechlorination under methanogenic conditions, yielding lower chlorinated species (mono-chlorobenzene and dichlorobenzenes). Trichlorobenzenes can potentially bioconcentrate in fish and other aquatic species, if exposed.

Polycyclic Aromatic Hydrocarbons (PAHs)

Polycyclic aromatic hydrocarbons (PAHs) are the primary group of semivolatile organic compounds (SVOCs) found in Block E soil. More than 100 different PAHs exist. Most of the common PAHs are typically formed during the incomplete burning of coal, oil, gas, wood, garbage, or other organic substances, such as tobacco and charbroiled meat. They are also found in substances such as asphalt, crude oil, coal, coal tar pitch, creosote, and roofing tar. In addition, they have been released to the environment from natural processes (such as volcanoes and forest fires) or can appear due to gradual deposition from industrialized areas, residential wood burning, and exhausts from automobiles and trucks. Throughout this RAP, discussions of PAHs focus on benzo(a)pyrene equivalents (BaPEq), a numerical expression calculated using the detected concentrations of the seven most toxic PAHs, and their relative toxicity as compared to benzo(a)pyrene.

Anthropogenic (man-made; e.g., in combustion byproducts such as fly ash) and industrial processes generally produce complex mixtures of PAHs (e.g., multiple PAH components) rather than single compounds. In terms of mobility, PAHs can enter surface water through discharges from industrial processes, atmospheric discharges, and wastewater treatment plants, and they can be released to soil at hazardous waste sites if they escape from storage containers.

The movement of PAHs in the environment depends on properties such as how easily they dissolve in water and how easily they bind to soil particles. As a rule, PAHs are large molecules with high organic partitioning coefficients, limited solubility, and low vapor pressures and Henry's Law Constants. PAHs tend not to easily dissolve in water, and generally enter groundwater as suspended solids or sorbed to particles that can be transported within an aquifer. PAHs in aquatic systems are primarily found sorbed to particles that have either suspended in or settled to the bottom of the water column, because of their low solubility and high affinity for organic carbon.

Both vapor pressure and water solubility are useful for determining PAH volatilization rates from surface water bodies and groundwater. The measured ratio of these two parameters under equilibrium conditions (i.e., the Henry's Law Constant) is used to calculate the equilibrium chemical concentrations in the vapor (air) phase as compared to the liquid (water) phase for the dilute solutions commonly encountered in environmental settings. In general, PAHs have a Henry's Law Constant less than 1×10^{-5} atmosphere cubic meter per mole (atm-m^3/mole) and should only minimally volatilize; thus, they should be present only in minute amounts within the atmosphere or soil vapor. However, PAHs with low molecular weights (such as acenaphthene, acenaphthylene, anthracene, fluorene, and phenanthrene) might more readily volatilize from soil (ATSDR, 1995).

PAHs in soil tend to bind to soil particles and be transported via mass-transport mechanisms rather than migrate through dissolution. Because of this, PAHs do not generally migrate vertically from surface soil. They are more likely to adhere to soil particles and be removed from the site via surface water runoff and erosional processes, especially in the absence of pavement, or if erosion controls are absent or not functioning properly. Sorption of PAHs to soil and sediment increases with increasing organic carbon content, and with increasing surface area of the sorbent particles. The rate and extent of PAH biodegradation in soil are affected by their physical and chemical properties and environmental factors: the organic content of soil, structure and particle size of the

soil, characteristics of the microbial population, and the presence of contaminants such as metals and cyanides that are toxic to microorganisms (ATSDR, 1995).

PAHs are ubiquitous and are generally irregularly distributed throughout MRC soil, including soil at Block E. PAH sources likely include urban-sourced fill and fires used to clear and burn brush. Although some Block E PAH concentrations in soil exceed risk-based screening values, primarily for benzo(a)pyrene, concentrations at MRC are generally low and likely indicative of historical use of impacted fill, and not PAH releases at the site.

3.2.3 Site-Specific Exposure Pathways

Industrial and construction workers are the receptors of concern at Block E. Current risk assessment guidance suggests that under foreseeable future property use, industrial workers could be exposed to chemicals in surface soil (zero to two feet below grade) through incidental ingestion and dermal contact, and through inhalation of airborne contaminants emanating from soil. Exposure to subsurface soil (two feet bgs and deeper) via incidental ingestion, dermal contact, and inhalation is considered a potential exposure pathway only for the construction worker, as the industrial receptor would be unlikely to contact soil at these depths.

If future construction were to bring subsurface soil to the surface, contaminants in Block E subsurface soil could then be transported through overland runoff, be captured in the storm drain system, and subsequently discharged to surface water, where recreational users could be exposed. Overland runoff of surface soil to surface water is generally not a significant contaminant transport mechanism, due to the flat topography, vegetative cover, and stormwater management at the site.

The present exposed and deteriorated condition of the Building D slab makes infiltration of surface water into soil likely; infiltration can move contaminated soil around under the slab or increase its potential leaching to groundwater. Contaminants in soil can migrate from both surface and subsurface soil to groundwater via leaching. Groundwater in the surficial aquifer at Block E generally flows south–southeasterly toward Dark Head Cove.

SECTION 4
CLEANUP CRITERIA

This section summarizes (1) the chemicals of concern (COC) and soil area/extent for which future remedial actions are necessary to reduce risk to current and future users of Tax Block E (Block E); (2) the preliminary remedial goals (PRGs) established for Block E COC as target levels for residual-risk analysis (RRA) and for confirmatory sampling; and (3) an overview of the RRA conducted to identify soil locations requiring remediation to achieve the remedial action objectives (RAOs) established for Block E soil. The RRA and preliminary PRG calculations for Block E soil are in Appendix C.

Block E soil is predominantly impacted by polychlorinated biphenyls (PCBs) and, to a lesser degree, by polycyclic aromatic hydrocarbons (PAHs) expressed as benzo(a)pyrene equivalents (BaPEq). These COC were identified in the 2012 human health risk assessment (HHRA) as the principal contaminants posing regulatorily unacceptable carcinogenic risks to potential site receptors (Tetra Tech, 2012f). Another COC identified in the HHRA is 1,2,4-trichlorobenzene (1,2,4-TCB), which is co-located with elevated concentrations of PCBs in limited areas.

Following the completion of the HHRA in 2012, investigations in Block E in 2013 revealed trichloroethene (TCE) in subsurface soil in the southeastern area of the site near an underground storage tank (UST). Updated risk calculations for the construction worker scenario using the 2012 HHRA methodology (Appendix C) identified TCE as a COC for future construction workers. In addition to TCE, PCBs (specifically, Aroclor 1254) were also detected in subsurface soil (e.g., primarily near the groundwater interface) in this area, and likewise pose an unacceptable noncarcinogenic risk to construction workers. (The risk assessment updates presented in the RRA consider soil excavations conducted in the southeastern portion of Block E and environmental data collected after preparation of the 2012 HHRA.) TCE impacts to soil and groundwater are being addressed by the groundwater response action because most of the TCE in this area is within the saturated soil.

The Block E remedial action is governed by Maryland Department of the Environment (MDE) requirements and is overseen by the MDE Land Restoration Program under Administrative Consent Order ACO-SAR-MDE0746-2015-1-01. To apply risk-based standards for PCB remediation, Lockheed Martin Corporation (Lockheed Martin) must apply in writing to the United States Environmental Protection Agency (USEPA) Region 3 regional administrator, in accordance with the risk-based disposal approval application (RBDAA) requirement (40 *Code of Federal Regulations* [CFR] 761.61[c]). Accordingly, risk-based cleanup methodologies are used herein to develop cleanup criteria for Block E COC in soil. After approval of this remedial action plan (RAP) and development of the full design, the RBDAA application will be submitted to USEPA for approval.

4.1 REMEDIAL ACTION OBJECTIVES

RAOs are developed to mitigate potential exposures that could be complete under the current or future land use scenarios identified in the conceptual site model (CSM). The following RAOs have been developed for impacted Block E soil:

Remedial action objective No. 1— Reduce site-related chemicals of concern in Block E soil to not exceed a cumulative human health cancer-risk limit of 1×10^{-5} and a cumulative noncarcinogenic hazard index of 1 for industrial and construction workers.

Remedial action objective No. 2— Prevent transfer of polychlorinated biphenyls to the extent practicable from surface soil and storm drains to discharged stormwater at concentrations that would affect the sediment remedy.

Remedial action objective No. 3— Prevent to the extent practicable leaching of polychlorinated biphenyls and 1,2,4-trichlorobenzene from soil to groundwater at concentrations that would impact surface water concentrations.

4.2 PRELIMINARY REMEDIATION GOALS

RAO No. 1 is to reduce Block E soil concentrations so that associated receptor risks are equal to or less than the cumulative residual cancer-risk level of 1×10^{-5} and a hazard index (HI) equal to or

less than 1 (on a target-organ-specific basis) for industrial and construction workers; this reduction must satisfy MDE requirements and be consistent with the requirements of Toxic Substance Control Act (TSCA) regulations under 40 CFR 761.61 and the *National Oil and Hazardous Substances Pollution Contingency Plan* (NCP) (40 CFR Part 300) promulgated under the federal Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). To achieve this RAO, risk-based PRGs were established for industrial and construction workers exposed to surface and subsurface soil COC in Block E. The Block E PRGs are summarized in Table 4-1.

Risk-based PRGs for the industrial and construction worker exposure scenarios were calculated for all surface soil and subsurface soil COC; these goals are presented in the *Technical Memorandum—Mr. Tom D. Blackman to Ms. Ruth Prince and Mr. James R. Carroll, Preliminary Remediation Goals for Industrial and Construction Workers, Block E Soil Remediation, Lockheed Martin Middle River Complex, Middle River, Maryland* (Lockheed Martin, 2018). The surface soil PRG for Aroclor 1260 (10 mg/kg) represents the 1×10^{-5} cancer risk level (i.e., a 1-in-100,000 excess probability of developing cancer). The surface soil PRG for BaPEq (2.9 mg/kg) represents the 1×10^{-6} (i.e., a one-in-a-million excess probability of developing cancer) cancer-risk level to meet the cumulative risk benchmark of 1×10^{-5}, and to be consistent with the PRG for BaPEq used at Blocks D, F, G, and H. The PRG selected for total PCBs (10 mg/kg) is also the conservative (lower) end of the recommended action level range for cancer risk presented in USEPA guidance for an industrial setting (see *A Guide on Remedial Actions at Superfund Sites with PCB Contamination* [USEPA, 1990]); the upper end of the action level range is 25 mg/kg. The surface soil PRGs for 1,2,4-TCB (330 mg/kg) and Aroclor 1254 (7 mg/kg) represent a hazard index (HI) of 1, and are less than (more restrictive than) the PRGs representing the 1×10^{-5} cancer risk levels.

PRGs for the construction worker exposure scenario were calculated for all subsurface soil COC (Lockheed Martin, July 2018). Industrial workers are unlikely to encounter subsurface soil; thus, they are not considered in the risk analysis. The subsurface PRGs for BaPEq (10 mg/kg), Aroclor 1254 (7 mg/kg), 1,2,4-TCB (530 mg/kg), and TCE (3.9 mg/kg) represent a hazard index (HI) of 1, and are less than (more restrictive than) the PRGs representing the 1×10^{-5} cancer risk levels. The subsurface PRG for Aroclor 1260 and total PCBs (58 mg/kg) represents the 1×10^{-5}

cancer risk level and is conservatively adjusted to a lower concentration in recognition of the combined risk attributed to both total PCBs and BaPEq.

All PRGs were calculated using the methodology presented in the HHRA, and verified using the USEPA regional screening-level calculator[3]. The associated check-calculation spreadsheets are in Attachment A of the RRA (Appendix C). Using Aroclor-specific PRGs for subsurface soil is appropriate, because different Aroclors are present at elevated concentrations in separate sub-areas of the site and are typically not co-located in sectors with regulatorily unacceptable risk.

PRGs used as a guide for target-sample removal were set at concentrations equal to MDE target risk-levels, but a cumulative residual-cancer-risk level of less than or equal to 1×10^{-5} (and/or a hazard index of 1, on a target-organ-specific basis) must be achieved after excavation and removal of impacted soil. For example, health risk to industrial workers is primarily driven by PCBs, so the final exposure-point concentration for Aroclor 1260 in surface soil might be less than, but close to, the industrial worker PRG (10 mg/kg). However, the final BaPEq exposure-point concentration for industrial workers must also be lower than the PRG of 2.9 mg/kg to achieve a cumulative-risk level of 1×10^{-5}. The apportionment of risk among COC is flexible, depending on the outcome of the RRA and the final calculation of exposure-point concentrations that include post-excavation sampling.

4.3 CHEMICALS OF CONCERN (COC)

PCB Aroclors are the primary COC in soil at Block E, with elevated concentrations primarily associated with identified PCB source areas (Transformer Rooms 2, 3, and 4, and the southeastern area). As investigations progressed from 2003 to 2015, chlorobenzenes were identified as a solvent component associated with the PCB source areas in Block E. PAHs expressed as BaPEq are also identified as COC, although BaPEq are present at relatively low levels as compared to Aroclors. In addition, BaPEq is ubiquitous in Block E soil, and in soil within other tax blocks of the Middle River Complex (MRC).

TCE was identified as a COC in surface and subsurface soil in the southeastern area of Block E. TCE is primarily present in saturated soil, and likely originates from a UST release. TCE in

[3] http://epa-prgs.ornl.gov/cgi-bin/chemicals/csl_search

Block E saturated soil is being addressed under the groundwater response action (see Section 2.4.6.4).

The discussion of COC below is organized by geographical areas at Block E to facilitate concise presentation on maps (Figures 4-1 to 4-17). Chemical results are compared to the Block E-specific, risk-based PRGs (Lockheed Martin, 2018) presented in Section 4.2. These PRGs were developed in the residual risk analysis (RRA), as summarized in Section 4.4 (Tetra Tech, 2018d).

4.3.1 Chemicals of Concern for Concrete

Only limited characterization of Block E concrete has been performed (see Figure 4-1), because the entire concrete slab will be removed and disposed of off-site during the remedial action. Chemical concentrations in concrete were not evaluated in the HHRA, because the concrete will be removed (and therefore its associated exposure pathway is incomplete). However, contamination associated with concrete will be subject to disposal requirements. Concrete will be tested during the remedial action to determine proper disposal requirements.

All concrete samples were analyzed for PCBs, and a subset (23 samples) was analyzed for metals and radionuclides. Positive PCB detections (as Aroclors), the primary Block E contaminant, were compared to the allowable TSCA special handling and disposal concentration of 50 milligrams per kilogram (mg/kg) for total Aroclor (see Appendix D, Table D-1). This value is used because it addresses the disposal requirements for the concrete that will be removed or displaced to access underlying contaminated soil. Aroclor 1260 at two locations in former Transformer Room 2, and at six locations in former Transformer Room 4, exceed the TSCA special-handling concentration. Complete analytical results for concrete are in Table D-1 (Appendix D). Figure 4-1 shows the collection locations of concrete samples with Aroclor concentrations exceeding the TSCA special-handling concentration; these locations are within or near the former transformer rooms.

4.3.2 Chemicals of Concern for Surface Soil

This section summarizes surface soil COC in relation to the predominant sub-areas of soil impacts at Block E. Figures 4-2 through 4-8 depict surface soil sampling locations and results exceeding PRGs.

Transformer Room 2 and Northwest Quadrant

Six surface soil samples in the northwestern quadrant of Block E had PCB concentrations exceeding the PRG (10 mg/kg) for Aroclor 1260 (or total PCBs). Aroclor 1260 was detected at concentrations slightly exceeding its PRG (19 mg/kg and 12 mg/kg) at two surface soil sampling locations just below the Block E slab (zero to one foot below slab, at SB-352 and SB-357, respectively). The Aroclor 1260 concentration was two orders of magnitude (i.e., 100×) greater (1,800 mg/kg) at a third sub-slab location in this area (SB-353).

Below the slab near Transformer Room 2, surface soil Aroclor 1260 concentrations exceed the PRG at three locations (E-SB-1447, E-SB-1494, and E-SB-1499, at concentrations of 5,300 mg/kg, 71 mg/kg, and 530 mg/kg, respectively). E-SB-1447 and E-SB-1494 are within the limits of former Transformer Room 2, and E-SB-1499 is adjacent and downgradient. The Aroclor 1260 concentration at E-SB-1447 (5,300 mg/kg) is the maximum concentration detected in surface soil at Block E. PCB concentrations in remaining surface soil samples in this sub-area are less than the PRG. Figure 4-2 shows the PCB exceedances for surface soil samples in the northwest quadrant.

PAH concentrations (expressed as BaPEq, and calculated based on positive detections only) exceed the PRG (2.9 mg/kg) in two northwestern area surface soil samples (E-SB-1446 and E-SB-1496), with respective concentrations of 4.5 and 8.8 mg/kg. The locations of BaPEq exceedances coincide with Transformer Rooms 1 and 2 (see Figure 4-7). BaPEq in surface soil are co-located with elevated Aroclor concentrations in Transformer Room 2, and would likely be addressed by any remedial action addressing PCBs, as treatment options for these chemicals are similar. No VOC concentrations exceeding PRGs were detected in surface soil in the northwestern quadrant of Block E (Figure 4-8).

Northeast Quadrant

As shown in Figure 4-3, one PCB (Aroclor 1260) concentration (E-SB-364) exceeded its PRG in Block E surface soil samples collected in the northeast quadrant. However, BaPEq concentrations at 16 surface soil locations in the northeastern quadrant exceed the PRG (Figure 4-7). BaPEq concentrations ranging from 3.78 to 10.25 mg/kg at two sampling locations (E-SB-965 and

E-SB-1258) near the eastern end of the soil pile are just above the PRG (2.9 mg/kg) (see Figure 4-17).

Concentrations of BaPEq detected at 13 surface-soil sampling locations within a grass covered island near the northeastern corner of former Building D, and at one location just south of that island, equaled or exceeded the PRG (Figure 4-7). The BaPEq concentrations in these samples, all collected from the top six inches or one foot of soil (i.e., from 0 to 1 foot below ground surface [ft bgs]), range from 2.9 mg/kg (E-SB-1492, 0–0.5 ft bgs) to 18.9 mg/kg (E-SB-1489, 0–0.5 ft bgs). No VOC concentrations exceed PRGs in surface soil samples in the northeast quadrant (Figure 4-8).

Transformer Room 4 and Southwest Quadrant

Surface soil PCB exceedances are interspersed throughout the southwest quadrant, including surface soil samples in grassy median areas, below concrete foundation slabs, and beneath the former Transformer Room 4 floor (Figure 4-4). The PRG exceedances in this area are attributed to Aroclor 1260; no Aroclor 1254 exceedances were found in this area. Aroclor 1260 concentrations greater than or equal to 1,000 mg/kg were detected in four surface soil samples: E-SB-1475 (1,000 mg/kg), E-SB-864 (1,100 mg/kg), E-SB-852 (3,300 mg/kg), and E-SB-1461 (4,200 mg/kg). The maximum concentration (4,200 mg/kg) in this area was detected approximately 10 feet southwest of former Transformer Room 4. Figure 4-4 shows the PCB exceedances for surface soil samples in the southwest quadrant.

Aroclor 1260 concentrations in 36 other surface soil samples in the southwest quadrant are less than 1,000 mg/kg, but exceed the PRG (10 mg/kg). Four surface soil samples had concentrations exceeding the PRG below Transformer Room 4: E-SB-833F (25 mg/kg), E-SB-984 (990 mg/kg), E-SB-833E (360 mg/kg), and E-SB-833K (680 mg/kg). A few exceedances were also detected in surface soil samples below the slab, northeast of former Transformer Room 4: SB-349 (24 mg/kg); SB-350 (55 mg/kg); SB-351 (21 mg/kg); and SB-4A-SS (180 mg/kg). Other Aroclor 1260 exceedances in surface soil are primarily scattered throughout the grassy areas along the southwestern end of former Building D, likely due to historical accidental discharges of transformer oils and/or runoff from contaminated surfaces following demolition of the building. This area along the southern perimeter of the building includes an unpaved swale running east to

west; surface soil in this swale will be removed as part of the Block E soil remedial action, due to its elevated concentrations of PCBs and BaPEq.

BaPEq was detected in 11 surface soil locations in the southwest quadrant at concentrations exceeding its PRG (Figure 4-7). Again, these concentrations were primarily found in the grassy island next to the former Building D slab. The maximum BaPEq concentration in this area is at E-SB-974 (45.1 mg/kg) in the unpaved swale. The other BaPEq exceedances in the southwest quadrant are in the grassy island and unpaved swales, including three locations next to Chesapeake Park Plaza (Figure 4-7). No VOC exceedances of PRGs were detected in surface soil samples in the southwestern quadrant area (Figure 4-8).

Transformer Room 3 and Southern Quadrant

Figure 4-5 shows PCB exceedances in surface soil samples from the southern quadrant. Surface soil PCB exceedances are interspersed throughout the southern quadrant, including in surface soil samples from grassy median areas, below concrete-foundation slabs, and beneath the former Transformer Room 3 floor. The second and third greatest Aroclor 1260 concentrations in surface soil were detected in the southern quadrant, at E-SB-1501 (4,900 mg/kg) and E-SB-1589 1-2 ft (4,500 mg/kg). Sample E-SB-1501 is in former Transformer Room 3, and E-SB-1589 is approximately 60 feet east of the room. One other detection greater than 1,000 mg/kg is at SB-529 (1,500 mg/kg), in the grassy island about 30 feet southwest of former Transformer Room 3.

Other Aroclor 1260 exceedances were found in surface soil below the former Building D slab in the southern quadrant, with concentrations up to several hundred milligrams per kilogram. Many exceedances are concentrated in surface soil throughout the grassy island next to the slab and near former Transformer Room 3, as well as in the unpaved swale south of that. Surface soil in the grassy islands and swale along the southern portion of Block E will likely be removed as part of the remedial action, due to their elevated PCB and BaPEq concentrations.

BaPEq concentrations (Figure 4-7) exceed the PRG (2.9 mg/kg) in 11 southern-quadrant surface soil samples, with the maximum concentration collected at a depth of 1.5 ft bgs at sampling location PUSTB (60 mg/kg), at the location of a geophysical anomaly that was a suspected UST, but was later determined to be metal debris. The other BaPEq exceedances in the southern quadrant

are in the grassy island and unpaved swales, including two next to Chesapeake Park Plaza. No VOC concentrations exceed their respective PRGs in surface soil samples in the southern quadrant (Figure 4-8).

Southeastern Aroclor 1254 Area

In the southeastern Block E area (termed the "Aroclor 1254 area" due to elevated Aroclor 1254 concentrations), 23 PRG exceedances for Aroclor 1260 and 19 exceedances for Aroclor 1254 were detected (Figure 4-6). This area is the location of a former 500,000-gallon diesel fuel aboveground storage tank (AST). Aroclor 1254 surface soil samples exceeding the PRG are largely within a radius of 40 feet to the north and southeast of the former AST.

Aroclor 1254 exceedances of the Block E surface soil PRG (7 mg/kg) range from 7.7 mg/kg to 930 mg/kg. Aroclor 1260 surface soil sample exceedances in this area are primarily around the southwestern footprint of the former AST, and up to 60 feet west. Aroclor 1260 concentrations exceeding the surface soil PRG (10 mg/kg) in this area range from 12 mg/kg to 80 mg/kg. In the southeastern Aroclor 1254 area, only two surface soil samples have BaPEq exceedances: E-SB-982 (3.6 mg/kg) and E-SB-1528 (12.5 mg/kg). BaPEq exceedances are shown on Figure 4-7.

The southeastern Aroclor 1254 area is the only area at Block E in which VOC concentrations exceed PRGs in surface soil. Concentrations of TCE exceeding the surface soil PRG (3.9 mg/kg) were detected at E-SB-1032 (5 mg/kg) and E-VB-11-072913 (7,500 mg/kg). Both samples were collected below the concrete slab north of the former AST, near the recently constructed groundwater bioremediation system wells and piping (Figure 4-8).

In 2014, after one year of multi-phase extraction treatment-system operation, soil sampling indicated that TCE concentrations at E-VB-11 had been reduced from 8,000 mg/kg (2013) to a level below its MDE cleanup standard, representing a decrease of over three orders of magnitude (1,000×). In subsequent sampling (in 2016) around E-VB-11 (E-SB-1513 through E-SB-1517), TCE was either not detected or was lower than its PRG (e.g., the maximum detected concentration was 0.14 mg/kg in E-SB-1514-2-4, and below PRG of 3.9 mg/kg). These data support the

conclusion that TCE is not currently present at high concentrations in vadose zone soil near E-VB-11 (Tetra Tech, 2018a).

4.3.3 Chesapeake Park Plaza Median Soil

An August 2018 investigation assessed concentrations of PCBs in surface soil along the center median and southern median bordering the roadway adjoining Block E to Chesapeake Park Plaza (Tetra Tech, 2019a). The objectives of this sampling were to evaluate the concentrations and extent of PCBs in median soil adjacent to, and potentially receiving surface runoff drainage from, Block E to determine whether action is required to prevent potential migration to Dark Head Cove surface water (in the context of RAO No. 2), given that nearby storm drain inlets discharge to the cove. An additional objective was to determine if PCBs migrated across the median to the southern perimeter of Chesapeake Park Plaza along Block F.

A series of 49 shallow borings were advanced within the median drainage swale located in the middle of the road between Blocks E and F, and in the grass on the southern edge of Chesapeake Park Plaza in Block F (Tetra Tech, 2018c). Soil samples were collected at three depths (0-0.5 feet [ft], 0.5-1 ft, and 1-2 ft) in each boring and analyzed for PCBs. Samples collected from the terminal depth of 1-2 ft bgs were frozen upon receipt by the laboratory and placed on hold, pending analysis of the two shallower intervals. The median surface soil sample locations and PCB results are shown on Figure 4-9.

The results of the August 2018 median investigation indicate that total PCB concentrations exceeding the TSCA unrestricted use/residential limit of 1,000 micrograms per kilogram (µg/kg) are in the top one foot of median soil, primarily in 21 samples collected from the center of the roadway. PCB concentrations in Block F surface soil (0-6 inches bgs) at five sampling locations on the southern side of Chesapeake Park Plaza also exceed this criterion. The highest Aroclor-1260 concentration detected in the median was 12,000 µg/kg, while the highest detected concentration along the border of Block F was 4,700 µg/kg.

PCB concentrations detected in the 0.5-1.0–foot depth at locations CPP-SB-1828, CPP-SB-1829, and CPP-SB-1854, all in the center median, triggered laboratory analysis of the (deeper) frozen (1-2–foot) samples from these borings. Of these three, PCBs were detected in only one sample

(CPP-SB-1854-1-2), at a concentration (29 µg/kg) well below the screening level used in this assessment.

The specific source for PCBs detected in median area surface soil is unknown. Possible historical origins may include deposition of particulates or dust released during demolition of former Building D, possible inadvertent releases during past transport and/or storage of demolition debris or former transformer components after the building was razed, or past inundation and flooding of the existing concrete slab and former Building D stormwater system (e.g., overland flow to median areas near stormwater inlets). The impacted soil in the Chesapeake Park Plaza center median is adjacent to the boundary of Block E, so an action addressing these elevated PCB concentrations will be incorporated into the Block E soil remedy (see Section 5.4.1). Surface soil exhibiting elevated PCB concentrations (i.e., greater than 1,000 µg/kg) on the southern side of Chesapeake Park Plaza in Block F are being assessed independently under a separate program.

4.3.4 Chemicals of Concern for Subsurface Soil

This section summarizes Block E subsurface soil COC. Figures 4-10 through 4-16 depict subsurface soil sampling locations and results exceeding PRGs. For simplification, Figures 4-10 through 4-14 depict only the PCB results for the deepest sampling interval in which Aroclor concentrations exceed the PRG. Additional sampling results were obtained in these borings, including exceedances at shallower depths.

The subsurface soil overlying the deepest exceedance might be addressed during remediation if chemical concentrations exceed subsurface soil PRGs. Alternately, some shallower subsurface soil without exceedances might not require remediation, but could instead be treated or excavated as an ancillary measure while remediating deeper, impacted soil. The complete data set, including PRG exceedances for all sampling depths, is in Appendix D. Figures depicting total PCB concentrations in soil at various depths are in Appendix G.

Transformer Room 2 and Northwest Quadrant

Subsurface soil in the former Transformer Room 2 area was not significantly sampled until investigations in 2016 and 2017. In 2016, PCBs were delineated in subsurface soil by sampling eight soil borings in the Transformer Room 2 area. In 2017, deeper subsurface soil was delineated

by collecting samples during two phases of investigation from an additional 19 borings advanced in the northwest quadrant and around Transformer Room 2.

As shown in Figure 4-10, eight boring locations constitute the horizontal extent of subsurface Aroclor 1260 contamination exceeding the PRG; all are either within the interior of former Transformer Room 2 or are within a 20-foot perimeter of its footprint. The maximum Aroclor 1260 concentration at depth (6–8 ft bgs) in this area was detected at sampling location E-SB-1499 (9,400 mg/kg). Deeper samples collected from six to 20 feet at this boring location in October 2017 (E-SB-1740) exhibit decreasing concentrations with depth (Tables D-3 and D-4).

The deepest PRG exceedance for Aroclor 1260 in this area was at E-SB-1613 at 18–20 ft bgs (190 mg/kg); this boring was advanced in the north-central interior of the former Transformer Room 2. Other deep subsurface soil exceedances for Aroclor 1260 range from 100 mg/kg (E-SB-1616 4–6 ft bgs) to 2,300 mg/kg (E-SB-1494 12–14 ft bgs). The vertical extent of Aroclor 1260 concentrations exceeding the PRG in the footprint of the former Transformer Room 2 ranges from two to 20 feet bgs (Figure 4-10 and Appendix D). Figure 4-10 shows that the deepest PCB exceedances in subsurface soil samples were collected in the northwest quadrant in and around Transformer Room 2. No BaPEq or VOC exceedances of their respective PRGs were detected in subsurface soil in the northwest quadrant (see Figures 4-15 and 4-16, respectively).

Northeast Quadrant

As shown in Figure 4-11, subsurface samples in the northeast quadrant are primarily from scattered soil borings advanced through the former Building D slab to assess possible historical subsurface impacts in former manufacturing and process areas. Aroclor 1260 concentrations detected in subsurface soil in the northeast quadrant do not exceed the PRG, except for two soil borings in the eastern end of former Transformer Room 2 (E-SB-1447 and E-SB-1620; see Figure 4-11). The deepest subsurface soil samples exceeding PRGs in these samples were at E-SB-1447, at 2-4 feet bgs (290 mg/kg) and at E-SB-1620, at 12–14 feet bgs (200 mg/kg).

These concentrations and depths fall within the range of exceedances detected in subsurface soil in the former Transformer Room 2 area, as discussed above. No BaPEq or VOC exceedances of

their respective PRGs were detected in subsurface soil in the northwest quadrant (see Figures 4-15 and 4-16, respectively).

Transformer Room 4 and Southwest Quadrant

Aroclor 1260 and total Aroclor concentrations in Block E subsurface soil are greatest in the former Transformer Room 4 area, in the southwest quadrant (Figure 4-12). The deepest Aroclor 1260 exceedances in Block E subsurface soil are at 18–20 ft bgs in this area, similar to the vertical extent of exceedances in Transformer Room 2. However, the horizontal extent of PCB Aroclors and Aroclor 1260 exceedances is most extensive in former Transformer Room 4, as compared to other Block E sub-areas. The deepest Aroclor concentrations exceeding PRGs in subsurface soil samples were collected in the southwest quadrant and Transformer Room 4.

Most Aroclor 1260 subsurface soil exceedances in the southwest quadrant consist of samples collected at two to 16 ft bgs below the building slab, in borings to the northwest and south of former Transformer Room 4 (Figure 4-12 and Appendix D). The deepest Aroclor 1260 concentrations exceeding the PRG in subsurface soil outside the former transformer room range from 61 mg/kg to 31,000 mg/kg (Figure 4-12). Within Transformer Room 4, the deepest subsurface soil exceedances range from 120 mg/kg to 780 mg/kg (in E-SB-984 at 12–14 ft, and E-SB-853 at 12-16 ft bgs, respectively). The greatest Aroclor 1260 concentration (31,000 mg/kg) in subsurface soil in this sub-area was in E-SB-1551, at 4–6 ft bgs (approximately 10 feet north of the northwestern corner of the former transformer room). Former sub-slab utilities near Transformer Room 4 might have served as a migration conduit for PCBs in this area; subsurface Aroclor 1260 concentrations at depths of two to 14 ft bgs in seven other soil borings within 20 feet (laterally) of E-SB-1551 exceed the PRG.

Exceedances were detected in subsurface Aroclor 1260 concentrations at five borings aligned along a north–south axis, starting approximately 40 feet northwest of Transformer Room 4. The deepest exceedances in these locations (E-SB-833A, E-SB-833I, E-SB-848, E-SB-827, and E-SB-1465) range from 99 mg/kg to 2,000 mg/kg, at depths between six and 16 ft bgs. The linear alignment of these subsurface exceedances (Figure 4-12), without co-located surface soil exceedances, suggests a utility conduit or other preferential flow path might be in this area.

Many Aroclor 1260 exceedances in surface soil were detected in the grassy island area adjoining former Building D just south of Transformer Room 4 (see Figure 4-12). Subsurface Aroclor sampling results for this grassy island indicate vertical distribution of Aroclor 1260 exceedances at depths up to 20 ft bgs. Aroclor exceedances in the deepest samples from this area range from 380 mg/kg to 13,000 mg/kg (E-SB-1597 8–10 ft bgs and E-SB-1598 10-12 ft bgs, respectively). No subsurface Aroclor 1260 exceedances were detected in the unpaved swale area near the middle of the southwestern quadrant, although surface soil exceedances were found in this area.

Another deep Aroclor 1260 exceedance (240 mg/kg) was detected at E-SB-1476 at 16–20 ft bgs, approximately 20 feet northeast of Transformer Room 3. Aroclor 1260 was detected at a concentration below the PRG (0.087*J* mg/kg; where "*J*" indicates an estimated concentration) in a deeper sample collected from E-SB-855 (24–28 ft bgs) approximately 15 feet south of E-SB-1476, suggesting limited horizontal extent of Aroclor 1260 in the SB-1476 area.

In the southwest quadrant, only one PRG exceedance for BaPEq was detected (33.2 mg/kg at E-SB-833, at 9 ft bgs). This appears to be an isolated PAH detection, as multiple samples collected in subsurface soil in the surrounding borings had no BaPEq detections (Figure 4-15).

Figure 4-16 shows the deepest VOC exceedances in subsurface soil in the southwest quadrant. PRG exceedances for 1,2,4-TCB were identified in two subsurface soil samples in this area. As described in Sections 2.4 and 3.1.2, chlorobenzenes can be considered a "companion" chemical to Aroclors in transformer oils. The maximum 1,2,4-TCB concentration (9,600 mg/kg) at E-SB-833 was at a depth of 9 ft bgs, approximately coincident with the groundwater interface.

At location E-SB-833A (10 ft bgs), 1,2,4-TCB also exceeds the subsurface soil PRG (530 mg/kg). The 1,2,4-TCB concentration (140 mg/kg) in a shallower sample from this boring (E-SB-833A at 6 ft bgs) does not exceed the PRG. As described further in Section 5.3, the presence of 1,2,4-TCB in these subsurface soil samples near the groundwater interface may indicate a release of PCB-containing hydraulic fluids to the groundwater at former Transformer Room #4.

Transformer Room 3 and Southern Quadrant

Aroclor exceedances near former Transformer Room 3 and in the southern quadrant are shown on Figure 4-13. Subsurface soil Aroclor 1260 concentrations exceed the PRG at five locations in the

footprint of former Transformer Room 3 (E-SB-1501, E-SB-1502, E-SB-1503, E-SB-1531, and E-SB-1734). The deepest Aroclor concentrations exceeding PRGs in subsurface soil samples from these borings ranges from 78 mg/kg (E-SB-1503 6–8 ft bgs) to 2,700 mg/kg (E-SB-1502 6-8 ft bgs). Samples from deeper intervals in soil borings advanced south of E-SB-1502 and analyzed for Aroclors show no exceedances. The deepest subsurface soil exceedance for Aroclor 1260 from below the Transformer Room 3 footprint was at 14-16 ft bgs in E-SB-1531 (850 mg/kg). Several peripheral Aroclor 1260 exceedances were detected in subsurface soil within an approximate 30-foot radius around former Transformer Room 3.

PRG exceedances were detected in subsurface soil samples from three borings south of the former transformer room: in E-SB-1507 at 4–6 ft bgs (1,300 mg/kg), in E-SB-1588 at 6–8 ft bgs (2,700 mg/kg), and in E-SB-1738 at 14–16 ft bgs (970 mg/kg). Other deep Aroclor 1260 subsurface soil exceedances detected around the perimeter of Transformer Room 3 range from 65 mg/kg at 20 feet west of the former room (E-SB-502 at 8–10 ft bgs) to 6,500 mg/kg at less than 10 feet east of former room (E-SB-1505 at 6–8 ft bgs). This is the highest Aroclor 1260 concentration among the deepest exceedances in the southern quadrant.

Five locations (shown on Figure 4-13 in the western end of this southern sub-area) have subsurface soil Aroclor 1260 exceedances. As they are on the western edge of the figure, these locations and exceedances are also shown on Figure 4-12 as part of the southwestern area, and are plotted here for completeness (but were discussed previously in Section 4.2.2.3). As shown on Figure 4-15, one subsurface soil BaPEq exceedance was detected at the southern quadrant location EW-2 at 5 ft bgs (17.8 mg/kg). In E-SB-1463 at 6–8 ft bgs (see Figure 4-16), the 1,2,4-TCB concentration (1,000 mg/kg) exceeds its PRG (530 mg/kg). No other BaPEq or VOC exceedances were detected in subsurface soil in the southern quadrant and former Transformer Room 3 area.

Southeastern Aroclor 1254 Area

Figure 4-14 shows the deepest Aroclor concentrations exceeding PRGs in subsurface soil samples collected in the southeastern quadrant. This area is the only area at Block E with subsurface soil (i.e., greater than two feet bgs) Aroclor 1254 concentrations exceeding the site-specific PRG for subsurface soil. This area contains both Aroclor 1254 exceedances and Aroclor 1260 exceedances, but Aroclor 1260 exceedances are mostly limited to surface soil (see Figure 4-6). One exception is

sample E-SB-1589, collected at 2–3 ft bgs near the southeastern edge of Building D, which had a subsurface Aroclor 1260 concentration (620*J* mg/kg) exceeding the PRG (see Figure 4-14).

The remaining exceedances in subsurface soil in the southeastern area consist of Aroclor 1254 in the top seven feet of soil. Deeper soil samples were tested here, but no exceedances were detected. Eight of 11 subsurface Aroclor 1254 exceedances were detected in the 2–4 ft bgs samples. The exceedances in this area are primarily within a 20-foot perimeter of the former 500,000-gallon diesel AST, ranging from 8.1 mg/kg (E-SB-1375 at 6–7 ft bgs) to 3,500 mg/kg (E-SB-1713 at 2-3 ft bgs).

One BaPEq exceedance (21.31 mg/kg) of the subsurface PRG (10 mg/kg) was detected in southeastern Block E area soil, slightly north of the Aroclor 1254 area, from 4 ft bgs at location PUSTGBR (see Figure 4-15). TCE concentrations in subsurface soil samples exceed the PRG (3.9 mg/kg) at 13 boring locations, in depths ranging from 5–30 ft bgs (see Figure 4-16).

As discussed previously, TCE in soil in this area is primarily associated with its elevated concentrations in groundwater. Shallow-soil TCE impacts in this area (e.g., 5–7 ft bgs) might be incidentally addressed as part of the soil remedial action to address PCBs in this area. However, we anticipate that the remaining, deeper TCE in saturated-zone soil will be addressed as part of the separate groundwater response action for Blocks E and F.

4.3.5 Soil Pile Chemical Results

Soil samples were collected for characterization in 2014 and 2016 from the soil piles along the northern and western perimeter of the former Building D foundation slab; soil samples had also been collected sporadically there before 2014. Figure 4-17 shows the location of soil pile samples. As discussed in Section 2, these pile or embankment areas contain soil obtained from the natural grade surrounding this area of Block E. This soil was slumped or pushed onto the foundation slab when the building was demolished, and has largely remained undisturbed since.

Discrete and composite samples were collected from throughout the pile at various depths, and analyzed for PAHs, PCBs, metals, and/or petroleum hydrocarbons. Since removal is planned for the piles that cover portions of the slab, characterization was necessary to determine soil handling and disposal.

Table D-8 (see Appendix D) shows chemical detections in Block E soil-pile samples, with results compared to risk-based soil PRGs calculated for Block E. PAH concentrations (expressed as BaPEq) in six surficial soil-pile samples exceed the PRG (2.9 mg/kg). As shown on Figure 4-17, these BaPEq exceedances are grouped into two small areas at the northern soil pile; exceedances are within 25 feet of each other in each group.

The first area is indicated by three soil samples collected above former Transformer Room 1 (E-SB-967-0–0.5 ft; E-SB-1261-0.5–1 ft; and E-SB-1262-0–0.5 ft). The second area includes three soil-pile samples collected near the northern central edge of Block E (E-SB-965-0–0.5 ft; E-SB-1258-0–0.5 ft; and E-SB-1258-0.5–1 ft). No BaPEq PRG exceedances were detected in soil-pile samples collected along the western perimeter of Block E, and no PRG exceedances for VOCs or Aroclors were detected in any soil-pile samples (see Table D-8).

Table E-7 (see Appendix E) contains the complete data results for soil-pile samples, including nondetect chemical results. The extent of soil within the piles where BaPEq exceeds PRGs is limited, rendering a small amount of the soil pile material unsuitable for backfill and requiring that it be removed and disposed of offsite. However, soil pile material that meets the requirements of the Soil Management Plan for Blocks E and I (Tetra Tech, 2019b) could be used for backfill during remedial actions involving excavation/removal (e.g., slab and underlying soil).

4.4 RESIDUAL RISK ANALYSIS

Several sampling events have been conducted at Block E since the 2012 human health risk assessment (HHRA) was prepared. Some screening criteria used to identify chemicals of potential concern (COPC) have changed since the 2012 HHRA evaluation. The residual risk analysis (RRA) was conducted subsequent to the HHRA, and is in Appendix C.

The RRA evaluation is conducted in six steps. As a first step, chemical concentrations in surface and subsurface soil are compared to the November 2017 USEPA regional screening levels (RSL) to determine if additional COPC need to be added. Surface soil is defined as all samples collected from zero to two feet below ground surface (bgs). (“Ground surface” and “soil surface” refer to the ground surface where the soil is exposed or the soil in contact with the bottom of the concrete where a foundation is present.) Subsurface soil is defined as two feet bgs to the vertical limit of

contamination. Subsurface soil is defined as two feet bgs to the vertical limit of contamination. The preliminary remediation goal (PRG) of 58 milligrams per kilogram (mg/kg) for Aroclor 1260 in subsurface soil is used to determine the vertical limit of contamination, which is 20 feet bgs.

The HHRA identified PCBs (predominantly Aroclor mixture 1260), carcinogenic PAHs evaluated as BaPEq, and 1,2,4-TCB as COC for exposure to surface soil in Block E (Tetra Tech, 2012f). No new COC were identified for surface soil. For subsurface soil, the HHRA results indicate that BaPEq, Aroclor 1254, Aroclor 1260, and 1,2,4-TCB are COC (Tetra Tech, 2012f).

Although not identified as a COC in the HHRA, TCE is considered a COC for subsurface soil for the RRA. TCE was detected at elevated concentrations in subsurface soil in the southeastern area of Block E after the discovery of a UST just outside the building foundation. This UST contained high concentrations of TCE and has since been removed; the groundwater response action is in progress in this area (see Section 2.2.3). Table 4-2 summarizes COC for Block E soil.

The second step in the RRA was to identify PRGs for the surface soil and subsurface soil COC. The PRGs for Block E COC are discussed in the section above and listed in Table 4-1.

The third step was to calculate cancer risks and hazard indices for all surface and subsurface soil samples and then rank the locations according to risk. Surface soil was treated as one exposure unit (EU) in the RRA. Subsurface soil was divided into five EUs for evaluation in the RRA: (1) Transformer Room 2 sub-area, (2) Transformer Room 3 sub-area, (3) Transformer Room 4 sub-area, (4) southeastern sub-area, and (5) site-wide subsurface soil excluding the other four sub-areas.

The fourth step consisted of iteratively removing samples and recalculating the exposure point concentration (EPC). All locations meeting the MDE “hot spot” definition were automatically identified as being targeted for remediation. Next, the locations contributing most significantly to calculated risk estimates (using professional judgment) associated with evaluated receptors were considered targeted for remediation. The selected data points (assuming removal via excavation) were replaced by “backfill” soil concentrations, and the EPC (equal to the 95% upper confidence limit [UCL] on the arithmetic mean) for each COC was recalculated using the substituted concentrations. The chemical concentrations in the backfill used at Block H were used as the

substitute concentrations. If the recalculated EPC exceeded the PRG for a receptor, additional locations were iteratively (one at-a-time) removed from the data set and replaced with the substitute concentration. The EPC was then recalculated until the resultant EPC was equal to or less than the PRG.

As explained in Appendix C, a margin of safety was applied to the evaluation in step 5. Given the large data sets for some of the EUs being evaluated, locations with highly elevated concentrations might possibly be "diluted out" by having many locations with low concentrations. To prevent this, "safety limits" were also used to identify samples requiring remediation.

For surface soil, all locations with Aroclor 1254 and Aroclor 1260 concentrations greater than 25 mg/kg were also targeted for removal. For subsurface soil, all locations with Aroclor 1254 and Aroclor 1260 concentrations greater than 100 mg/kg were targeted for removal. In the final step, receptor-specific risk estimates were recalculated for all COPC identified in step 1 (not just COC), to ensure that cumulative risk estimates were equal to or below the 1×10^{-5} cancer risk level, and less than a hazard index of 1 (Appendix C).

4.5 ATTAINMENT OF REMEDIAL ACTION OBJECTIVE NO. 1 USING RESIDUAL RISK ANALYSIS

The RRA identified the locations in Block E targeted for remediation to mitigate risks posed to the hypothetical industrial worker (exposed to surface soil) and construction worker (exposed to surface and subsurface soil) and to meet the RAOs; these locations are listed in the tables in Appendix C and are shown on Figures 4-18 and 4-19. A summary of the RRA results for each sub-area is presented below. PCBs (primarily Aroclor 1260) are the predominant COC for surface soil at Block E.

Fifty-one surface locations are targeted for remediation to achieve MDE risk management goals (i.e., less than a cumulative cancer risk level of 1×10^{-5} and cumulative hazard index of 1) for the industrial worker. As an additional margin of safety, all surface soil (0 to 2 feet below the soil surface) locations with PCB concentrations exceeding 25 mg/kg (an additional 52 locations) are also targeted for remediation. These locations are identified on Figure 4-18. The highest remaining Aroclor 1260 concentration would be 24 mg/kg, and the highest remaining Aroclor 1254

concentration would be 20 mg/kg. The residual cancer risk to an industrial worker exposed to surface soil would be 3×10^{-6} (i.e., a three-in-a-million probability), and the hazard index would be 0.2.

No locations are targeted for remediation to achieve MDE risk management benchmarks for subsurface soil, excluding the four sub-areas in Block E. Similar to the surface soil above, a safety margin was applied to subsurface soil in the sub-areas, as indicated in the paragraphs below. Following removal of targeted locations, the highest remaining Aroclor 1260 concentration is 22 mg/kg, and the highest Aroclor 1254 concentration is 0.038*J* mg/kg. The residual cancer risk to a construction worker exposed to subsurface soil would be 5×10^{-7}, and the hazard index would be 0.7.

At the Transformer Room 2 sub-area (unique from the sub-area discussed above), three subsurface locations are targeted for remediation to achieve MDE risk management benchmarks (Figure 4-19). As an extra margin of safety, six additional locations with Aroclor 1260 concentrations exceeding 100 mg/kg are also targeted for remediation. The highest remaining Aroclor 1260 concentration would be 31 mg/kg, and the highest remaining Aroclor 1254 concentration would be 0.095 mg/kg. The residual cancer risk to a construction worker exposed to subsurface soil would be 9×10^{-7} (i.e., a 9-in-10-million probability), and the hazard index would be 0.5.

Ten locations are targeted for subsurface soil remediation in the Transformer Room 3 sub-area to achieve MDE risk management benchmarks (Figure 4-19). As an extra margin of safety, 10 additional locations with Aroclor 1260 concentrations exceeding 100 mg/kg are also targeted for remediation. The highest remaining Aroclor 1260 concentration would be 65 mg/kg, and Aroclor 1254 is nondetect. The residual cancer risk to a construction worker exposed to subsurface soil would be 8×10^{-7} (i.e., an 8-in-10-million probability), and the hazard index would be 0.2.

Sixteen locations are targeted for subsurface soil remediation in the Transformer Room 4 sub-area to achieve MDE risk management benchmarks (Figure 4-19). An additional 16 locations had Aroclor 1260 concentrations exceeding 100 mg/kg, and as a margin of safety, these were targeted for remediation. Two locations targeted for removal had 1,2,4-trichlorobenzene concentrations

exceeding the PRG (530 mg/kg), and one location targeted for removal had a BaPEq concentration exceeding the PRG (10 mg/kg). The highest remaining Aroclor 1260 concentration would be 50 mg/kg, and Aroclor 1254 is nondetect. The residual cancer risk to a construction worker exposed to subsurface soil would be 1×10^{-6}, and the hazard index would be 0.9.

For the southeastern, Aroclor 1254 sub-area, six subsurface locations are targeted for remediation to achieve MDE risk management benchmarks (Figure 4-19). An additional three locations had Aroclor 1254 concentrations exceeding 100 mg/kg, and, as a margin of safety, these were targeted for remediation. The highest remaining Aroclor 1260 concentration would be 24 mg/kg, and the highest remaining Aroclor 1254 concentrations would be 80 mg/kg. The residual cancer risk to a construction worker exposed to subsurface soil would be 1×10^{-6}, and the hazard index would be 1.

This RAP evaluates remedial alternatives in terms of their ability to achieve the established RAOs for Block E soil according to regulatory guidelines and requirements (discussed in Section 5). Following implementation of the remedial action, post-remedial attainment samples for open excavations will be collected to ensure that RAO No. 1 has been achieved, and to ensure that soil requiring removal (per the RRA) from the ground surface to 20 feet below soil surface have been addressed.

The BaPEq and PCB Aroclor concentrations in post-remediation confirmatory samples will be used to recalculate residual risk, and sampling will be considered complete when soil from the required locations has been removed and calculation of the remaining residual risk complies with the requirements of RAO No. 1. Section 8 provides further details on the sampling that will be required to demonstrate attainment of target risk levels. Institutional controls for groundwater and any remaining impacted soil will be established as part of site closure. A "No Further Action" letter will be requested from MDE once RAOs have been met.

SECTION 5
REMEDIAL ACTION ALTERNATIVE DEVELOPMENT AND EVALUATION

Selected technologies and institutional controls for the proposed soil remedial actions are presented in this section, as required by regulations administered by the Maryland Department of the Environment (MDE) Land Restoration Program under Administrative Consent Order ACO-SAR-MDE0746-2015-1-01, and by federal requirements defined in 40 *Code of Federal Regulations* (CFR) Chapter I, United States Environmental Protection Agency (USEPA), Subtitle R, "Toxic Substances Control Act" (TSCA) 761.61(c). The *National Oil and Hazardous Substances Pollution Contingency Plan* (NCP) (40 CFR Part 300), promulgated under the federal Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), guides the selection of remedial technologies. The following are described in this section:

- identification, screening, and evaluation of potential technologies and process options
- selection of representative process options
- development and detailed analysis of alternatives
- preliminary screening and detailed evaluation of alternatives
- comparative analysis of alternatives
- identification of the recommended, proposed alternative

Technology identification and screening are based on the following steps:

- identification of chemicals of concern (COC) (Section 4)
- identification of applicable or relevant and appropriate requirements (ARARs) (Section 5)

- development of remedial action objectives (RAOs) (Section 4)
- development of COC preliminary remedial goals (PRGs) (Section 4)
- identification of general response actions (GRAs) (Section 5)

5.1 APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS

The ARARs in this remedial action plan (RAP) are any state or federal statute or regulation that pertains to the protection of human health and the environment in addressing specific conditions or use of a particular cleanup technology at a site. Other criteria that are non-promulgated, non-enforceable guidelines or criteria that might be useful in developing a remedial action, or that might be necessary to determine actions to protect human health and/or the environment, will be considered. Examples include United States Environmental Protection Agency (USEPA) industrial-exposure risk-based concentrations and similar MDE standards.

One of the primary concerns in developing remedial action alternatives for contaminated sites is the degree of human health and environmental protection offered by a given remedy. CERCLA Section 121 requires that primary consideration be given to remedial alternatives that attain or exceed ARARs. The purpose of this requirement is to make CERCLA remedial actions consistent with other pertinent federal and state environmental requirements.

The NCP identifies the following three categories of ARARs (40 CFR Section 300.400 [g]):

- ***Chemical-specific*—**Health-risk-based numerical values or methodologies that establish concentration or discharge limits for particular contaminants. Table 5-1 lists federal and Maryland chemical-specific ARARs and to-be-considered (TBC) criteria. These ARAR and TBC criteria provide some medium-specific guidance as to what concentrations of contaminants are deemed "acceptable" or "permissible" according to regulations.
- ***Location-specific*—**These ARARs restrict actions or contaminant concentrations in certain environmentally sensitive areas. Examples of areas regulated under various federal laws include floodplains, wetlands, and locations of endangered species or historically significant cultural resources. Table 5-2 lists federal and Maryland location-specific ARARs and TBC criteria. These ARARs and TBC criteria restrict contaminant concentrations or the conduct of activities solely based on the particular characteristics or location of the site.

- ***Action-specific*—**These ARARs are technology- or activity-based requirements, limitations on actions, or conditions, involving special substances that control or restrict remedial action. Examples of action-specific ARARs include wastewater discharge standards, and performance or design standards, controls, or restrictions on particular types of activities. Table 5-3 lists federal and Maryland action-specific ARARs and TBCs.

5.2 GENERAL REMEDIAL ACTIONS

General response actions (GRAs) are broadly defined remedial approaches that might attain RAOs. GRAs describe categories of actions that could be implemented to satisfy or address a component of an RAO for the site. GRAs corresponding to the RAOs are in Table 5-4. Remedial action alternatives will be developed using the following GRAs individually or in combination to meet the RAOs for contaminated soil in Block E:

- no action
- excavation
- treatment (*ex situ* or *in situ*)
- limited action (institutional controls)
- containment
- disposal

5.3 IDENTIFICATION AND SCREENING OF TECHNOLOGIES AND PROCESS OPTIONS

This section includes the identification, screening, and evaluation of technologies and process options possibly applicable to remedy Block E soil. The primary objective of this phase is to develop an appropriate range of remediation technologies and process options that will meet the RAOs. The remediation technologies and process options are identified based on team knowledge and experience and with application on similar projects. Publicly available information from the Federal Remediation Technologies Roundtable (FRTR) technologies screening-matrix tool (FRTR, 2012) was also used. The identified technologies and process options were screened in accordance with USEPA guidance (USEPA, 1988) and Lockheed Martin Corporation (Lockheed Martin)-specific considerations for sustainability and total cost analysis. Table 5-5 presents the technologies and process options identified and the screening results with respect to effectiveness, implementability, and relative cost. Descriptions of the evaluation criteria follow:

- *Effectiveness*: This criterion is used to screen out technologies as follows:

- Technologies and process options that were not effective in eliminating potential exposure pathways (in particular, for current industrial and construction workers), or were not effective for meeting an RAO, were screened out.
- Unreliable technologies and process options were screened out.

- *Implementability*: Technologies that cannot be implemented in the area were screened out.
- *Relative cost:* Technologies with costs that are significantly higher than others that achieve similar goals were screened out. Relative costs (such as high, medium, and low) are provided, based on experience with similar projects and publicly available information from the FRTR screening tool (FRTR, 2012).

The technologies and process options that passed the initial screening and detailed evaluation (see Table 5-5) were then selected for the next step in developing possible remedial alternatives for soil. Table 5-6 lists the technologies that were retained.

5.4 DEVELOPMENT AND DETAILED ANALYSIS OF ALTERNATIVES

This section discusses the development of the soil remedial-action alternatives from the process options retained above and describes the conceptual design for the selected short-list of alternatives. Impacted soil, as defined for the following discussion, is soil that the residual risk analysis (RRA) identified for remediation to achieve a site-wide cumulative cancer-risk level of 1×10^{-5} or a non-cancer risk of less than 1. Figures 5-1 through 5-11 depict the locations of the samples to be remediated per the RRA. Figures 5-1 and 5-6 provide an overall view of the site, and Figures 5-2 through 5-5 and 5-7 through 5-10 are at a smaller scale to provide better legibility. Figure 5-11 provides a comprehensive depiction of surface and subsurface soil sample locations to be removed.

A two-step process for identifying and evaluating alternatives was used for this RAP. First, an initial list of eight potential remedial action alternatives was developed from the process options retained during the preliminary screening of technologies. Advantages and disadvantages of each were identified, and the capital and operating costs for each alternative was estimated. After the initial list of eight options was screened during a qualitative analysis, five remedial alternatives were retained for further evaluation.

5.4.1 Development and Preliminary Screening of Alternatives

Eight alternatives were developed from the technologies and process options retained in Section 5.3. The development of these alternatives according to the RAOs and risk pathways is shown in Table 5-7. The following paragraphs describe each alternative in detail. Additional remedial activities that are common to all alternatives are described after the alternatives. For simplicity, the name of each alternative only includes the significant components.

For all alternatives except the "no action" alternative (Alternative 1) and Alternative 2, soil with PCB concentrations greater than 50 mg/kg is assumed to be disposed at a landfill rather than incinerated. Landfilling is assumed because of its lower costs as compared to incineration. Incineration is an acceptable method of disposal according to regulations and can be used if landfill space is limited.

Alternative 1—No action: This alternative will not meet the RAOs for site redevelopment and is presented only for comparison purposes.

Alternative 2—Placement of a TSCA-compliant cap over Block E and institutional controls: This alternative would place a TSCA-compliant cap over the impacted soil. The cap would be designed to include new grading requirements for stormwater control. The cap would be consistent with regulations outlined in 40 CFR 761.61(a)(7), and would comply with the permeability, sieve, liquid-limit, and plasticity-index parameters in 40 CFR 761.75(b)(1)(ii) through (b)(1)(v). This alternative would also require institutional controls for soil and groundwater. Figure 5-12 is a plan view of Alternative 2.

Alternative 3—Excavation and disposal of impacted surface and subsurface soil using conventional methods: The RRA identifies soil between zero to two feet below soil surface that need to be removed to meet risk-based criteria for industrial workers. ("Soil surface" refers to the ground surface where the soil is exposed or the soil in contact with the bottom of the concrete where a foundation is present.) Impacted soil would be excavated using conventional methods to a depth of two feet below soil surface and disposed of off-site, thus meeting the cumulative cancer-risk-based criterion of 1×10^{-5} and hazard index of 1 for industrial land use, using PRGs of 10 mg/kg (for Aroclor 1260 and total PCBs), 7 mg/kg (for Aroclor 1254), 2.9 mg/kg (for

benzo(a)pyrene equivalents [BaPEq]), and 330 mg/kg (for 1,2,4-trichlorobenzene [1,2,4-TCB]). This alternative does not include a point-by-point removal of all soil with PCB concentrations greater than PRGs; however, as a conservative approach, surface soil with total PCB concentrations greater than 25 mg/kg would also be removed. A two-foot depth is assumed for cost estimating purposes; however, the data can be further evaluated during the design phase such that excavation depths less than two feet can be proposed.

The RRA identified subsurface soil beneath two feet below the soil surface that needs to be removed to meet risk-based criteria for construction workers. Post-excavation confirmation samples would be collected from the sidewalls and bottom of the surface soil excavations. Saturated subsurface soil would be dewatered before excavation. Impacted soil would be excavated using conventional methods, up to a depth of 20 feet below soil surface and disposed of off-site, thus meeting the cumulative cancer-risk-based criterion of 1×10^{-5} and hazard index of 1 for construction worker exposure use, using PRGs of 58 mg/kg (for Aroclor 1260 and total PCBs), 7 mg/kg (for Aroclor 1254), 10 mg/kg (for BaPEq), and 530 mg/kg (for 1,2,4-TCB). This alternative does not include a point-by-point removal of all soil with PCB concentrations greater than PRGs; however, as a conservative approach, subsurface soil having total PCB concentrations greater than 100 mg/kg would also be removed.

For subsurface soil excavation, both sheet pile and unsupported wall methods were considered. In the former, sheet piles would be driven around the excavation area, followed by excavation of the soil within the piles. After the impacted soil has been removed, the excavation would be backfilled, and the sheet piles would be removed. The vertical walls of the excavation would minimize the amount of soil to be managed and would minimize the quantity of groundwater to be treated. Sheet piles typically entail a significant cost as compared to unsupported excavations. In addition, confirmation samples along the sidewalls could not be collected, because sheet piles would cover the sidewalls.

In the case of unsupported excavation walls, the sidewalls would be sloped at a ratio of 1:1 (horizontal to vertical), although steeper slopes may be considered during the final design. The additional soil removed to create the slope is assumed to be acceptable for site use and would be

stockpiled until the excavation has been completed. Samples of the excavated slope soil and confirmation samples from the sidewalls and bottom would then be collected.

After the impacted soil has been removed, the excavations would be backfilled to the original slab grade with both clean fill and the stockpiled slope soil. If the results of the analyses of the slope soil exceed PRGs, then that soil would be disposed of off-site. If the results of the confirmation samples exceed PRGs, then additional excavation, off-site disposal of soil, and backfill would be required. Preliminary cost estimates for two methods of sheet piling—cantilevered and anchored—and unsupported walls were developed, and the cost for the unsupported wall method was less than the cost for the sheet pile methods (see Appendix H). Therefore, for purposes of this RAP, excavations with unsupported walls will be assumed, but the sheet pile approach may still be used in the final design of this alternative.

Before subsurface excavation begins, the saturated zone will be dewatered, and the extracted groundwater treated before being discharged under a National Pollutant Discharge Elimination System (NPDES) Permit. Discharge to a sanitary sewer will be evaluated further during the final design. Dewatering will continue until backfilling is started. Following excavation, clean soil would be placed and compacted. This alternative would require institutional controls for soil that remains on-site and for groundwater.

Figure 5-13 shows the surface-soil excavation boundaries. Note that some surface soil in the southeastern area was excavated in 2015 as part of the groundwater bioremediation system installation, so excavation limits in the final design may be adjusted to account for this. Figure 5-14 shows the locations of samples with PCB concentrations low enough to be disposed of at a non-TSCA landfill. To conservatively estimate quantities, Figure 5-14 uses a value of 40 mg/kg as a threshold for non-TSCA disposal. Figure 5-15 shows the lateral extent of subsurface soil to be remediated to meet the subsurface PCB PRG, along with the sampling locations to be remediated per the RRA. Figure 5-16 shows the lateral extent of PCB-impacted subsurface soil to be remediated without the sampling locations, for clarity.

Figure 5-17 shows the lateral extent of subsurface soil to be remediated, along with the depth of remediation. Figure 5-18 combines the shallow soil excavation boundaries from Figure 5-13, and

shows the lateral extent of subsurface soil to be remediated from Figure 5-17. Figure 5-19 is a plan view of Alternative 3 that illustrates the additional soil to be excavated using excavation without sheet piles.

Alternative 4—Excavation of impacted surface soil using conventional methods and excavation of subsurface soil using large-diameter augers and off-site disposal: Impacted surface soil (as described in Alternative 3) would be excavated using conventional methods to a depth of two feet below soil surface and disposed of off-site. As noted for Alternative 3, the data can be further evaluated during the design phase, and additional samples can be collected such that excavation depths less than two feet can be proposed. Similarly, deeper impacted subsurface soil, as described in Alternative 3, would be excavated using large-diameter augers (five- to eight-feet in diameter) and disposed of off-site. Use of large diameter augers would eliminate the need for either sloped sidewalls for an excavation or sheet piling. Impacted subsurface soil at shallow depths (up to three to six feet below soil surface) would be excavated using conventional methods during the surface soil excavation.

Following excavation of the surface soil, clean soil would be placed and compacted. A large-diameter casing would be advanced to impacted subsurface soil, followed by removal of the soil within the casing using the large-diameter auger. Free water from the saturated zone in subsurface soil would be allowed to drain, and would be collected, treated, and discharged under an NPDES permit. Immediately after excavation, augered excavations would be filled with a high-cement content flowable fill.

The initial auger excavations would be placed on a square grid, and each boring would be tangent to adjacent boings. The soil between the initial borings would be augered out in a second pass which overlaps the initial borings and removes a portion of the flowable fill along with the contaminated soil. To remove all targeted impacted subsurface soil, a portion of the clean material in the previously backfilled borings would have to be removed and disposed of. The casing and the immediate addition of the flowable fill would prevent the collection of confirmation samples.

The existing deep foundation piles near Transformer Room No. 2, estimated to be 40 to 50 feet deep, might prevent the complete removal of impacted subsurface soil in that area. Pulling these

piles would open a pathway for contaminated groundwater to travel deeper into the aquifer. This alternative would require institutional controls for soil that remains on-site and for groundwater. Figure 5-20 is a plan view of Alternative 4.

Alternative 5—Excavation of impacted surface soil using conventional methods, with off-site disposal and* in situ *stabilization of subsurface soil using large-diameter augers: Impacted surface soil, as described in Alternative 3, would be excavated using conventional methods to a depth of two feet below soil surface and disposed of off-site. As noted for Alternative 3, the data can be further evaluated during the design phase, and additional samples can be collected such that excavation depths less than two feet can be proposed. Confirmation samples would be collected as described in Alternative 3.

Impacted subsurface soil, as described in Alternative 3, would be treated by mixing with Portland cement and clay *in situ* using large-diameter augers. This would prevent PCB and other COC contact by receptors on-site. Alternative 5 does not include an open excavation for the subsurface soil, so no confirmation samples would be collected from subsurface soil.

Following excavation of surface soil, clean soil would be placed and compacted. Part of the stabilized subsurface soil would be disposed of off-site, because mixing the subsurface soil with stabilization additives would increase its volume. This alternative would require institutional controls for soil that remain on-site and for groundwater. Figure 5-21 is a plan view of Alternative 5.

Alternative 6—Excavation of impacted surface and subsurface soil using conventional methods and on-site* ex situ *stabilization: Impacted surface soil (as described in Alternative 3) would be excavated using conventional methods to a depth of two feet below soil surface. As noted for Alternative 3, the data can be further evaluated during the design phase, and additional samples can be collected, such that excavation depths less than two feet can be proposed. Confirmation samples would be collected as described in Alternative 3. Similarly, impacted subsurface soil, as described in Alternative 3, would be excavated using conventional methods. Confirmation samples for the subsurface soil excavations would be collected as described in Alternative 3.

After excavation, impacted soil would be mixed with Portland cement and clay. Stabilization will prevent receptor contact with PCBs and other COC. Stabilized soil would be used as backfill for the surface and subsurface soil excavations. Part of the impacted soil will be disposed of off-site, because mixing the subsurface soil with stabilization additives would increase its volume. This alternative would require institutional controls for soil that remains on-site and for groundwater. Figure 5-22 is a plan view of Alternative 6.

Alternative 7—Excavation of impacted surface soil using conventional methods, with off-site disposal and* in situ *thermal desorption of subsurface soil: Impacted surface soil (as described in Alternative 3) would be excavated using conventional methods to a depth of two feet below soil surface and disposed of off-site. As noted for Alternative 3, the data can be further evaluated during the design phase, and additional samples can be collected, such that excavation depths less than two feet can be proposed. Confirmation samples would be collected as described in Alternative 3. Impacted subsurface soil, as described in Alternative 3, would be treated by *in situ* thermal desorption (ISTD) to meet risk-based criteria to protect construction workers.

Subsurface soil would be heated *in situ* to a temperature of 350 degrees Celsius (ºC) or higher via conductive heating, using high-temperature heater wells and a vacuum applied through a soil-vapor extraction system. The off-gas vapors would be processed through a vapor treatment system consisting of compression, cooling, and condensation components that will condense the vapors. The liquid produced would be properly disposed. A sheet-pile barrier around each treatment area would be required to maintain temperature, dewater the area, and minimize water inflow. Confirmation samples for the subsurface soil treatment would be collected using direct-push technology (DPT) methods within the treatment zones. The treated clean soil would be placed and compacted following excavation of the surface soil. This alternative would require institutional controls for soil that remains on-site and for groundwater. Figure 5-23 is a plan view of Alternative 7.

Alternative 8—Excavation of impacted surface and subsurface soil using conventional methods and on-site* ex situ *thermal desorption: Impacted surface soil (as described in Alternative 3) would be excavated using conventional methods to a depth of two feet below soil surface. As noted for Alternative 3, the data can be further evaluated during the design phase, and additional samples

can be collected, such that excavation depths less than two feet can be proposed. Confirmation samples would be collected as described in Alternative 3. Similarly, impacted subsurface soil, as described in Alternative 3, would be excavated using conventional methods. Confirmation samples for the subsurface soil excavations would be collected as described in Alternative 3.

After excavation, impacted soil would be treated on-site in a temporary indirect-fired thermal desorption system and heated to a temperature of 350ºC or higher. PCBs that condense from the vapor phase would be disposed of off-site at an incinerator. The balance of the PCBs in the off-gas would be treated on-site in a thermal oxidizer.

Treated soil would be analyzed to confirm that the target treatment level was met, and then used as backfill in the surface and subsurface soil excavations. The system would be operated 24 hours per day and six days per week for approximately 14 weeks. This alternative would require institutional controls for soil that remains on-site and for groundwater. Figure 5-24 is a plan view of Alternative 8.

Common elements—All alternatives except Alternative 1 (the "no action" alternative, and others as noted) share the common elements listed below. Most of these elements are depicted on Figure 5-25, except as noted below:

- Removing soil piles from atop portions of the building foundation. As noted in Section 4.2.4, most of this soil can be used as backfill.

- Installing a temporary retaining wall on the western side of the slab. The retaining wall will stabilize the adjacent Tilley Chemical Company property during removal of the western soil pile and allow access to the complete basement floor slab of former Building D. Cantilevered-soldier pile-wall and anchored-soldier pile-wall designs were evaluated, and the anchored design would be a lower cost (see Appendix H).

- Surveying the foundation slab, subgrade soil, and drain lines for possible radioactive residue from materials that might have historically been used at former Building D, and verifying that any radioactive material above release limits has been removed so that the site can be released without restrictions. All radioactive material identified during radiological surveys will be packaged, removed to a material accumulation area, sampled for offsite disposal facility Waste Acceptance Criteria and staged for offsite shipment. General activities would include work-area surveys, monitoring for personnel protection during demolition, contamination surveys of equipment and materials for disposal, and reporting (see Appendix I). A graded approach to radiological controls would be employed

during remediation, with the primary focus on the southwest quadrant; however, all remediation activities would be radiologically monitored. *(Note: this is not depicted on Figure 5-25.)*

- Abandoning monitoring wells within the footprint of the slab and excavation areas. Wells outside the slab footprint and excavation areas along with injection wells and piping associated with the groundwater treatment system in the southeastern area would be protected from damage. Abandoned monitoring wells, which are needed for post-excavation monitoring, would be replaced.

- Demolition and disposal of Building D foundation slab, footings, and pile caps, and leaving foundation piles in place. Piles exposed during excavation will be cut and removed.

- Removal and disposal of sub-slab cast iron floor drain piping.

- Demolition and disposal of other concrete and asphalt pavement within Block E; uncontaminated concrete and asphalt can be broken up and recycled on-site.

- Removing the recognized environmental condition (REC) #2 product pipeline that traverses Block E, under the oversight of a Baltimore County Oil Control Program (OCP) inspector, and in compliance with Code of Maryland Regulations (COMAR) Title 26.10. Confirmation samples will be collected and analyzed as described in Section 7.7. (This action is being conducted to ensure that any possible contamination resulting from historical releases within the pipeline are remediated.)

- Excavation and disposal of the top one foot of soil in the median of Chesapeake Park Plaza and replacing it with clean backfill. This will prevent potentially PCB-impacted soil from eroding and discharging through the storm sewer.

- Removing storm sewers and associated impacted soil below the sewer pipe, rerouting stormwater through newly installed stormwater channels and sewer, and improving site grading (see Appendix J). Where storm sewers are removed beneath existing and proposed channels, clean backfill will be used to restore the surface of the channel to prevent erosion of potentially PCB-impacted soil by the storm water flowing through the channel.

- Surface restoration by backfill, using clean fill, loam, and seed in all disturbed areas (except Alternative 2, which would have specific materials in the cap design). Backfill is needed to restore the surface to the top of the original foundation slab plus additional backfill and topsoil for contouring per the final stormwater management design (see Appendix J). Clean soil will be placed between final stormwater channel bottoms and residual PCB-impacted soil to prevent erosion of PCB-impacted soil by stormwater flowing through the channels. *(Note: this is not depicted on Figure 5-25.)*

- Two years of semiannual groundwater sampling in downgradient wells. As shown on Figure 5-26, with groundwater analyzed for PCBs and 1,2,4-TCB. *(Note: this is not depicted on Figure 5-25.)*

- Cost assumptions— All facilities below are Lockheed Martin-approved for use. *(Note: this is not depicted on Figure 5-25)*:

    - Soil and concrete with PCB concentrations 50 mg/kg and greater would go to a TSCA-approved hazardous waste landfill (for example, CWM Chemical Services, LLC in Emelle, Alabama). To conservatively estimate quantities, a value of 40 mg/kg was used as a threshold for non-TSCA disposal.

    - All other soil and concrete that require disposal would go to a nonhazardous landfill (for example, Waste Management—Fairless Landfill in Morrisville, Pennsylvania). Uncontaminated concrete would be broken up and recycled on-site as backfill.

    - Groundwater collected from excavations would be treated on-site and discharged via an NPDES permit.

- Institutional controls, including prohibitions on groundwater use, soil handling requirements, and limitations on future use of the property. MDE is anticipated to require that these institutional controls be included on property deeds. *(Note: this is not depicted on Figure 5-25.)*

- Miscellaneous considerations, such as finishing the backfilled areas with grass. *(Note: this is not depicted on Figure 5-25.)*

- Post-excavation verification sampling and sampling for disposal characterization. *(Note: this is not depicted on Figure 5-25.)*

The database which shows the residual contamination would be made available to the construction contractor to prevent known exposures during maintenance of existing Block E utilities, and during new utility installations and future development, even if such development complies with future industrial use plans for the site.

Elimination of alternatives—The following alternatives were eliminated based on the analysis of the remedial goals, advantages, disadvantages, and costs described above:

- ***Alternative 2:*** This alternative would only place a TSCA-regulated cap over the site, thus leaving all impacted soil in place. By leaving the soil in place, RAO No. 1 would not be met, and PCBs and 1,2,4-TCB could continue to leach from soil to groundwater; thus, RAO No. 3 would not be met. This alternative also greatly restricts future property uses. For these reasons, Alternative 2 was removed from consideration.

- ***Alternatives 5 and 6:*** Although these alternatives would meet the cumulative cancer-risk-based criterion of 1×10^{-5} for the industrial and the construction worker scenarios by removing or stabilizing impacted soil and preventing contact with PCBs and COC, a bench-scale study (see Appendix K) found that stabilization was not effective at this site. The high

proportion of fines in the soil limits the ability of the additives to bind to the soil and to COC. For this reason, Alternatives 5 and 6 were removed from consideration.

Accordingly, Alternatives 1, 3, 4, 7, and 8 are retained and carried forward for further evaluation. Table 5-8 shows the alternatives retained after the preliminary screening.

5.4.2 Evaluation Criteria

The five alternatives that passed the preliminary screening were evaluated in more detail using the nine evaluation criteria presented in the NCP. The NCP evaluation criteria provide a framework for assessing the risks, benefits, and costs of each remedial alternative. A tenth criterion, "Sustainability," has been added per Lockheed Martin policy. The 10 criteria are as follows:

1) overall protection of human health and the environment
2) compliance with ARARs
3) long-term effectiveness and permanence
4) reduction in toxicity, mobility, and volume through treatment
5) short-term effectiveness
6) implementability
7) costs
8) sustainability
9) state acceptance
10) local acceptance

The first two criteria, overall protection of human health and the environment and compliance with ARARs, are *threshold criteria*. All alternatives evaluated (except Alternative 1: No Action) meet these criteria.

The next five criteria described in the NCP are the *primary balancing criteria*. The evaluation in this RAP also adds a sixth balancing criterion that considers the sustainability of each alternative. Thus, the six primary balancing criteria considered are as follows:

1) long-term effectiveness and permanence
2) reduction in toxicity, mobility, and volume through treatment
3) short-term effectiveness
4) implementability
5) costs
6) sustainability

***Long-term effectiveness and permanence*—**Alternatives were assessed for their long-term effectiveness and permanence, along with the degree of certainty that the alternative will succeed. Other considerations include, as appropriate, the magnitude of residual risk (e.g., risks posed by untreated waste or treatment residuals) and the adequacy and reliability of controls (e.g., controls needed to manage untreated waste or treatment residuals).

***Reduction of toxicity, mobility, or volume through treatment*—**Alternatives were assessed for the degree to which they use recycling or treatment that reduces the toxicity, mobility, or volume of the waste being assessed, including how the treatment and associated reduction addresses principal site risks. The treatment aspect of this criterion reflects the CERCLA statutory preference for treatment.

***Short-term effectiveness*—**The short-term effects of the alternative were assessed considering the following:

- short-term risks that might be posed to the community during implementation
- potential effects on workers during the remedial action and the effectiveness and reliability of protective measures
- potential environmental effects of the remedial action, and the effectiveness and reliability of mitigation measures during implementation
- time until protection is achieved

***Implementability*—**The ease or difficulty of implementing the alternatives were assessed by considering technical feasibility, administrative feasibility, and availability of services and materials.

***Costs*—**Total cost analysis (TCA) considers the costs associated with implementing a program, including direct costs associated with implementation, environmental and health costs, risks and liabilities, and costs borne by others. The TCA considered five cost categories for the Block E soil remediation alternatives, as follows:

I—Direct costs (recurring and non-recurring), including:

- remediation design
- remediation construction, including capital, labor, material, and waste disposal
- operation, maintenance, and monitoring
- decommissioning and disposal upon remedy completion
- worker safety measures

II—Indirect costs (recurring and non-recurring) expended by Lockheed Martin to manage and support the remediation program.

III—Future and contingent liability costs, including:

- fines and penalties
- natural resource damage assessments under CERCLA
- property damage
- disposal or recycling facility failures
- future development under institutional controls
- currently unknown issues, such as:
    - unknown contamination in the remediation area or under the operating manufacturing facilities
    - future releases to groundwater
    - effect of future modification or demolition of manufacturing facilities, including changes in groundwater flow and contaminant release
    - emerging chemicals of concern

IV—Internal intangible costs, including:

- community relations
- regulatory relations
- corporate image
- customer loyalty
- worker wellness and morale

V—External costs (borne by society), including:

- environmental deterioration
- resource depletion
- protection of future residents and workers

The TCA, as applied in this soil RAP, includes quantitative cost estimates for Categories I and II and qualitative cost assessments for Categories III, IV, and V. Qualitative assessments are generally included in the other CERCLA evaluation criteria. TCA results are in Appendix H.

Sustainability—This is not an NCP criterion; it was added to comply with Lockheed Martin policy. The sustainability of the remedial alternatives was assessed using the *SiteWise*™ software tool (Appendix L). *SiteWise*™ is a spreadsheet-based tool developed by the United States Navy, United States Army Corps of Engineers, and Battelle Memorial Institute. It provides a model for assessing the environmental footprint of remedial alternatives in terms of a consistent set of metrics, including greenhouse gas emissions, particulate emissions, and energy usage. The components of Alternatives 3, 4, 7, and 8 were divided into four modules (representing the remedial phases of most remedial actions), and the environmental footprint of each was calculated; these results were then combined to determine the total footprint of each alternative, and to enable comparison among the set of alternatives. *SiteWise*™ can also be used to determine the primary footprint contributors of each alternative.

The last two criteria described in the NCP are *modifying criteria*: state and local acceptance. Lockheed Martin has proactively interacted with MDE, USEPA, and the local community to present and discuss the potential ramifications of potential alternatives. MDE approval of the RAP will constitute state acceptance. USEPA approval of the risk-based disposal approval application (RBDAA) will constitute federal acceptance. Lockheed Martin is committed, through its community outreach program, to giving the public opportunities to comment on the RAP before its final approval and implementation. The two modifying criteria will not be scored during evaluation of the remedial actions at this time but will be incorporated after MDE has reviewed this document, USEPA has reviewed the RBDAA, and community input on this RAP has been received.

5.4.3 Detailed Analysis of Alternatives

The following sections detail the five alternatives retained based on the primary balancing criteria presented in Section 5.4.2.

5.4.3.1 Alternative 1: No Action

Long-term effectiveness and permanence—Alternative 1 would not be effective in the long-term at meeting RAOs, because site COC would remain in soil above the 1×10^{-5} human health cancer-risk limit and noncancer HI of 1. This alternative would not reduce risk and would not address transport of surface and storm sewer contaminants by stormwater to Dark Head Cove sediment, nor prevent leaching of contaminants to groundwater.

Reduction of toxicity, mobility, and volume through treatment—Alternative 1 does not employ any treatment; and, no reduction of toxicity, mobility, or volume of COC would be achieved.

Short-term effectiveness—No negative impacts are associated with the no action alternative, beyond the potential transport of surface contaminants by stormwater to Dark Head Cove water and sediment, and the continued regulatorily unacceptable human health exposure risk. Concentrations of soil-COC might gradually decrease to regulatorily acceptable levels over a long period due to natural processes; however, it would take a very long time to reach RAOs if no action is performed.

Implementability—Alternative 1 poses no implementability concerns because no action would be implemented.

Sustainability—No air emissions or impacts to water resources would be caused by this alternative, because no action would be implemented.

Cost—No costs are associated with Alternative 1.

5.4.3.2 Alternative 3: Excavation and Disposal of Impacted Surface and Subsurface Soil Using Conventional Methods

Alternative 3 would meet surface and subsurface soil PRGs through excavation and off-site disposal. Surface soil with PCB concentrations greater than 25 mg/kg, and subsurface soil with PCB concentrations greater than 100 mg/kg, were also identified for removal, to provide a margin of safety. Institutional controls would also be applied.

Long-term effectiveness and permanence—Alternative 3 would be effective in the long-term because average site-wide residual risk of both surface and subsurface soil would be reduced to

regulatorily acceptable human health risk levels after implementation of this alternative, thus meeting RAO No. 1. Removal of contaminants in surface soil, the removal of storm drains, and use of clean soil in storm water swales and channels would prevent transfer of PCBs to stormwater, thus meeting RAO No. 2. Removal of the subsurface source area would further reduce potential leaching of PCBs and 1,2,4-TCB in soil to groundwater, thus meeting RAO No.3. Implementation, monitoring, and enforcement of institutional controls would also provide long-term effectiveness in protecting human health.

Reduction of toxicity, mobility, and volume through treatment—Alternative 3 would remove impacted soil from the site and dispose of it at an off-site landfill, thus reducing the mobility of contaminants. Toxicity and volume of contaminants would not be reduced by implementation of this alternative, because soil would be moved to another location, rather than being treated to destroy contamination.

Short-term effectiveness—Construction associated with this alternative would pose insignificant risk to the surrounding community and on-site workers. During the excavation of impacted soil, the primary risk to the community would be from inhalation of the dust produced. This risk would be mitigated through implementation of workplace dust-monitoring and dust-suppression measures as needed. Monitoring and appropriate personal protective equipment would mitigate risk to workers. Traffic (approximately 1,700 truckloads of impacted soil, 300 truckloads of concrete, and 3,000 truckloads of backfill) and noise during implementation of this alternative would have an effect on the surrounding community, and peak construction hours and planned trucking routes would be set to reduce this. Alternative 3 would take approximately seven months to reach RAOs.

Implementability—Personnel and equipment to design and implement the proposed actions are readily available, and time to coordinate with stakeholders and obtain the necessary permits can be built into the schedule. Identification and field location of utilities and other features that could interfere with construction would also be required during the design process, and before intrusive construction began. With these considerations, Alternative 3 is implementable.

Sustainability—The following environmental effects were estimated using *SiteWise*™ (see Appendix L):

- greenhouse gas emissions— 2,500 metric tons
- water impacts— 12,000 gallons
- nitrogen oxides (NO_x) emissions— 2.9 metric tons
- sulfur oxides (SO_x) emissions— 0.97 metric tons
- particulate matter (PM_{10}) emissions— 2.0 metric tons
- total energy used— 160,000 million British Thermal Units (MMBTU)

Cost—The following cost was estimated for Alternative 3:

- total cost: $ 21,920,000

5.4.3.3 Alternative 4: Excavation of Impacted Surface Soil Using Conventional Methods and Excavation of Subsurface Soil Using Large-Diameter Augers and Off-Site Disposal

Alternative 4 would meet surface and subsurface soil PRGs through conventional excavation of surface soil and large diameter auger excavation of subsurface soil and off-site disposal, although existing foundation piles, estimated to be 40 to 50 feet deep, near Transformer Room No. 2 will inhibit complete removal of impacted subsurface soil. Because of the foundation piles, approximately 1–2% of the total impacted subsurface soil would be left behind. Removal of those piles, if possible considering their length, would provide a pathway to contaminate deeper groundwater in the aquifer. Surface soil with PCB concentrations greater than 25 mg/kg, and subsurface soil with PCB concentrations greater than 100 mg/kg, were also identified for removal, to provide a margin of safety. Institutional controls would also be applied.

Long-term effectiveness and permanence—Alternative 4 would be effective in the long-term, because average site-wide residual risk of surface soil would be reduced to regulatorily acceptable human health risk levels after implementation of this alternative, thus meeting RAO No. 1. However, it might not be possible to remove the existing deep foundation piles near Transformer Room No. 2. These piles will interfere with the placement of the augers and prevent complete removal of the impacted subsurface soil, as would take place in some other alternatives. Removal

of contaminants in surface soil, the removal of storm drains, and use of clean soil in stormwater swales and channels would prevent transfer of PCBs to stormwater, thus meeting RAO No. 2. Removal of most of the subsurface source area would further reduce potential leaching of PCBs and 1,2,4-TCB in soil to groundwater, thus meeting RAO No.3. Implementation, monitoring, and enforcement of institutional controls would also provide long-term effectiveness in protecting human health.

Reduction of toxicity, mobility, and volume through treatment—Alternative 4 would remove impacted soil from the site and dispose of it at an off-site landfill, thus reducing the mobility of contaminants at the site. Toxicity and volume of contaminants would not be reduced by implementation of this alternative, because soil would be moved to another location, rather than being treated to destroy contamination.

Short-term effectiveness—Construction associated with this alternative would pose insignificant risk to the surrounding community and on-site workers. During the excavation of impacted soil, the primary risk to the community would be from inhalation of the dust produced. This risk would be mitigated through implementation of workplace dust-monitoring and dust-suppression measures as needed. Monitoring and appropriate personal protective equipment would mitigate risk to workers. Traffic (approximately 1,700 truckloads of impacted soil, 300 truckloads of concrete, and 3,000 truckloads of backfill material) and noise during implementation of this alternative would have an impact on the surrounding community, and peak construction hours and planned trucking routes would be set to reduce this impact. Alternative 4 would take approximately eight months to reach RAOs.

Implementability—Personnel and equipment to design and implement the proposed actions are available, although few contractors are capable of large-diameter auger excavation. Time to coordinate with stakeholders and obtain the necessary permits can be built into the schedule. Identification and field location of utilities and other features that could interfere with construction would also be required during the design process, and before intrusive construction began. With these considerations, Alternative 4 is implementable.

***Sustainability*—**The following environmental effects were estimated using *SiteWise*™ (see Appendix L):

- greenhouse gas emissions— 3,200 metric tons
- water impacts— 462,000 gallons
- NO_x emissions— 4.6 metric tons
- SO_x emissions— 1.7 metric tons
- PM_{10} emissions— 6.8 metric tons
- total energy used— 140,000 MMBTU

***Cost*—**The following cost was estimated for Alternative 4:

- total cost: $ 23,280,000

5.4.3.4 Alternative 7: Excavation of Impacted Surface Soil Using Conventional Methods with Off-Site Disposal and *In Situ* Thermal Desorption of Subsurface Soil

Alternative 7 would meet surface and subsurface soil PRGs through conventional excavation of surface soil and off-site disposal, and ISTD of subsurface soil. Surface soil with PCB concentrations greater than 25 mg/kg, and subsurface soil with PCB concentrations greater than 100 mg/kg, was also identified for removal or treatment, to provide a margin of safety. Institutional controls would also be applied.

***Long-term effectiveness and permanence*—**Alternative 7 would be effective in the long-term, because average site-wide residual risk from both surface and subsurface soil would be reduced to regulatorily acceptable human health risk levels after soil excavation and after thermal desorption have been completed, thus meeting RAO No.1. However, uncertainty exists in quantifying the effectiveness of ISTD, because this technology has had few applications addressing PCBs. Removal of contaminants in surface soil, the removal of storm drains, and use of clean soil in stormwater swales and channels would prevent transfer of PCBs to stormwater, thus meeting RAO No. 2. Treatment of the subsurface soil would further reduce potential leaching of PCBs and 1,2,4-TCB to groundwater, thus meeting RAO No.3. Implementation, monitoring, and

enforcement of institutional controls would provide long-term effectiveness in protecting human health.

Reduction of toxicity, mobility, and volume through treatment—Alternative 7 would remove impacted surface soil from the site and dispose of it at an off-site landfill, thus reducing contaminant mobility. Contaminant mobility, toxicity, and volume would be reduced in the subsurface soil through treatment by implementation of *in situ* thermal desorption. PCBs removed by ISTD would be recovered and destroyed off-site using a thermal process.

Short-term effectiveness—Construction associated with this alternative would pose insignificant risk to the surrounding community and on-site workers. During implementation of Alternative 7, the primary risk to the community would be from dust inhalation generated during excavation, and from potential vapor during *in situ* thermal desorption. The vapor treatment system would have to comply with TSCA regulations for PCB removal (99.9999%), because the soil has PCB concentrations greater than 50 mg/kg. Community risks would be mitigated through implementation of workplace dust monitoring and dust- and vapor-suppression measures, and state-of-the-practice vapor treatment. Through system operation, vapor samples would be collected, and maintenance performed to confirm that no hazardous substances are discharged to the environment.

Monitoring and appropriate personal protective equipment will address potential risk to workers. Traffic (approximately 550 truckloads of impacted surface soil, 300 truckloads of concrete, and 2,000 truckloads of backfill) and noise during implementation of this alternative would have an impact on the surrounding community. Peak construction hours and planned trucking routes would be set to reduce the impact. Alternative 7 would take approximately 14 months to reach RAOs.

Implementability—Personnel and equipment to design and implement the proposed actions are available. A limited number of contractors can perform *in situ* thermal desorption. As noted above in long-term effectiveness, quantifying the effectiveness of ISTD treatment is uncertain, because few applications of this technology have addressed PCBs. Sheet piles and dewatering for the subsurface soil treatment would be required. Time to coordinate with stakeholders and obtain the necessary permits can be built into the schedule. Identification and field location of utilities and

other features that might interfere with construction would also be required during the design process, and before intrusive construction begins. With these considerations, Alternative 7 is implementable.

Sustainability—The following environmental effects were estimated using *SiteWise*™ (see Appendix L):

- greenhouse gas emissions— 5,900 metric tons
- water impacts— 3,500,000 gallons
- NO_x emissions— 7.6 metric tons
- SO_x emissions— 25 metric tons
- PM_{10} emissions— 2 metric tons
- total energy used— 190,000 MMBTU

Cost—The following cost was estimated for Alternative 7:

- total cost: $31,720,000

5.4.3.5 Alternative 8: Excavation of Impacted Surface and Subsurface Soil Using Conventional Methods and On-Site *Ex Situ* Thermal Desorption

Alternative 8 would meet surface and subsurface soil PRGs through excavation and on-site treatment. Surface soil with PCB concentrations greater than 25 mg/kg, and subsurface soil with PCB concentrations greater than 100 mg/kg, were also identified for removal, to provide a margin of safety. Institutional controls would also be applied.

Long-term effectiveness and permanence—Alternative 8 would be effective in the long-term, because average site-wide residual risk of both surface and subsurface soil would be reduced to regulatorily acceptable human health risk levels after implementation of this alternative, thus meeting RAO No. 1. Removal of contaminants in surface soil, the removal of storm drains, and use of clean soil in stormwater swales and channels would prevent transfer of PCBs to stormwater, thus meeting RAO No. 2. Removal and treatment of impacted subsurface soil would further reduce potential leaching of PCBs and 1,2,4-TCB to the groundwater, thus meeting RAO No. 3.

Implementation, monitoring, and enforcement of institutional controls would also provide long-term effectiveness in protecting human health.

Reduction of toxicity, mobility, and volume through treatment—Alternative 8 would reduce contaminant mobility, toxicity, and volume in the surface and subsurface soil through treatment by implementation of *ex situ* thermal desorption. PCBs that are removed in the vapor phase would be destroyed on-site using thermal processes, and PCBs recovered in liquid phase, such as condensate, would be destroyed off-site using thermal processes.

Short-term effectiveness—Construction associated with this alternative would pose insignificant risk to the surrounding community and on-site workers. During the excavation of impacted soil, the primary risk to the community would be from inhalation of the dust produced during excavation, stockpiling, and preparation before treatment. This risk would be mitigated through implementation of workplace dust-monitoring and as needed dust-suppression measures. There would also be potential risk to the community during thermal treatment of the soil. The vapor treatment system would have to comply with TSCA regulations for PCB removal (99.9999%), because the soil has PCB concentrations greater than 50 mg/kg. Community risks would be mitigated through implementation of dust monitoring and dust- and vapor-suppression measures and state-of-the-practice vapor treatment. Through system operation, vapor samples would be collected, and maintenance performed to confirm that no hazardous substances are discharged to the environment.

Monitoring and appropriate personal protective equipment will mitigate risk to workers. Traffic (300 truckloads of concrete and 1,400 truckloads of backfill) and noise during implementation of this alternative would have an impact on the surrounding community. Peak construction hours and planned trucking routes would be set to reduce the impact. Alternative 8 would take approximately nine months to reach RAOs.

Implementability—Personnel and equipment to design and implement the proposed actions are available. A limited number of contractors can perform *ex situ* thermal desorption and meet the required TSCA PCB destruction efficiency (99.9999%). Similarly, a limited number of portable treatment systems are available, which could affect scheduling. Time to coordinate with

stakeholders and obtain the necessary permits can be built into the schedule. Identification and field location of utilities and other features that could interfere with construction would also be required during the design process, and before intrusive construction began. With these considerations, Alternative 8 is implementable.

Sustainability—The following environmental effects were estimated using *SiteWise*™ (see Appendix L):

- greenhouse gas emissions— 3,600 metric tons
- water impacts— 1,700,000 gallons
- NO_x emissions— 6 metric tons
- SO_x emissions— 12.7 metric tons
- PM_{10} emissions— 1.3 metric tons
- total energy used— 140,000 MMBTU

Cost—The following cost was estimated for Alternative 8:

- total cost: $ 24,690,000

5.5 COMPARATIVE ANALYSIS OF ALTERNATIVES AND PROPOSED ALTERNATIVE

Qualitative (see Section 5.4) and quantitative methods were used to compare the five remedial action alternatives for Block E soil. Both methods use the same evaluation criteria described in previous sections. As discussed above, this evaluation does not incorporate the state acceptance or community acceptance criteria; these will be evaluated through input from the community, USEPA, and MDE following submittal of this RAP and the RBDAA for regulatory approval.

A multi-criteria comparative decision-analysis was performed to quantitatively evaluate the potential alternatives. This method is useful because criteria such as environmental benefits, impacts, risk, economics, and stakeholder participation are not easily condensed into simple evaluation matrices. A multi-parameter analysis tool incorporates the decision criteria for remedy selection, assignment of weights to each criterion, and then summing the weighted scores for each criterion, resulting in a total quantitative score for each alternative for comparison. The score

applied to each remedial alternative is clearly defined and readily available for review. In addition, this tool enables the user to determine which criteria the scores are most sensitive to and to easily add alternative variants based upon results from earlier runs.

In this RAP, the multi-parameter analysis tool *Criterium® DecisionPlus®* (CDP) was used to weight and score the remedial alternatives for Block E. *Criterium® DecisionPlus®* is a decision-support tool that incorporates simple multi-attribute rating techniques such as the analytical hierarchy process and the Multi-Attribute Utility Theory (InfoHarvest, 2001). To build the decision hierarchy and incorporate all decision factors, each NCP evaluation criterion is represented by one or more individual metrics.

These metrics are represented by up to three levels of evaluation criteria as follows: Level 1 criteria are the major balancing and modifying criteria; Level 2 criteria include factors considered when evaluating Level 1 criteria; and Level 3 has further subcomponents with which to evaluate the Level 2 criteria. The results of this screening are in Appendix M. Table 5-9 summarizes the qualitative CDP analysis. Table 5-10 summarizes the weightings, rankings, and results of the quantitative CDP analysis.

All retained alternatives (excluding the "No Action" alternative) evaluated meet the threshold criteria equally well; therefore, the six balancing criteria were used to differentiate among alternatives and determine the preferred alternative:

- ***Long-term effectiveness and permanence—***Alternative 3 would reduce risk by remediating to very conservative cumulative risk goals, and by addressing impacted soil both above and below the water table. Alternative 7 ranks below Alternative 8 because ISTD has not been used at many PCB sites, and both alternatives rank below Alternative 3 in this category, because they would reduce risk by remediating to very conservative cumulative risk goals, and by addressing impacted soil both above and below the water table. Uncertainty exists regarding the effectiveness of the thermal technology on the PCBs and fine material. Alternative 4 is ranked somewhat lower than the other alternatives, because subsurface soil near the existing foundation piles cannot be removed by auger.

- ***Reduction of toxicity, mobility, or volume by treatment—***Alternatives 7 and 8 rank highest in this category, because they could achieve a high level of COC destruction where applied, and treatment would be complete and irreversible, because COC would be oxidized.

- ***Short-term effectiveness***—Alternative 1, "No Action," has the highest rank for this criterion. Alternative 8 ranks the next highest because it entails much less truck traffic

through the community during implementation. Alternative 7 ranks below Alternative 8 because of the track traffic needed for disposal and backfilling the surface soil. Alternatives 3 and 4 are similar, because of the truck traffic associated with the surface and subsurface soil disposal. On the other hand, Alternatives 7 and 8 could potentially release COC via the vapor phase.

- ***Implementability—***Alternative 3 ranks highest in this category (other than "No Action") because the technology and expertise to execute this alternative are readily available and it is easily constructible. Alternative 4 is next, because of the limited number of companies that can perform large-diameter auger excavation. Alternative 7 would be next after that, because only a limited number of companies perform ISTD. Alternative 8 would be most difficult to implement, because of the on-site soil handling requirements, and operation of the thermal and off-gas treatment systems. Moreover, only a limited number of companies perform *ex situ* thermal desorption, and only a limited number of *ex situ* thermal desorption systems are available.

- ***Sustainability—***Alternative 1 ranks highest in this category, because no corrective action would be taken; therefore, no impacts to the environment would occur through its implementation. Alternative 3 ranks second highest in this category, with the lowest amount of greenhouse gas emissions and NO_x emissions. This alternative is followed in order by Alternatives 4, 8, and 7.

- ***Cost—***Alternative 1 ranks highest (i.e., has the lowest cost) in this category, followed in order by Alternatives 3, 4, 8, and 7.

The overall *Criterium*® *DecisionPlus*® scoring of the various alternatives is as follows (higher scores indicate that the alternative is more highly or favorably ranked):

- Alternative 1—0.111
- Alternative 3—0.266
- Alternative 4—0.214
- Alternative 7—0.193
- Alternative 8—0.216

Alternative 3 is the highest ranked alternative. Alternative 3 would meet RAO No. 1 for all Block E COC, including PCB Aroclors, 1,2,4-TCB, and BaPEq. Alternative 3 would meet RAO No. 2 by adding clean soil backfill and vegetation to proposed stormwater channels so that potentially impacted soil would not be carried away by stormwater and would meet RAO No. 3 by removing the source of PCBs and 1,2,4-TCB to groundwater. Alternative 3 is time- and cost-effective, uses conventional construction methods, has the lowest environmental effects, and

would allow the site to be accessible in the future. Thus, Alternative 3 was selected as the proposed soil remedial action at Block E, based on both the qualitative and quantitative analyses.

Alternative 4 would remove most, but not all, of the impacted subsurface soil, so it was not selected. Alternatives 7 and 8 have higher associated costs than the other alternatives, uncertainty in effectiveness of technologies, and have larger environmental footprints as compared to the other alternatives.

The chosen alternative, Alternative 3, will require institutional controls, including prohibitions on groundwater use, soil handling requirements, requirements for sub-slab soil-vapor-mitigation technology on future buildings, and limitations on future property uses. Contingency requirements for the proposed alternative are discussed in Section 6. Documentation of residual contamination will be necessary to prevent known exposures during maintenance of existing Block E utilities, new utility installations, and future site development, even if such development complies with the future industrial use plans of the site.

SECTION 6
CONTINGENCY MEASURES FOR THE PROPOSED REMEDIAL ACTION

The proposed remedial alternative chosen for Block E (Alternative 3) includes removal of impacted soil in areas identified by the residual-risk analysis (RRA) to reduce industrial- and construction-worker risk to achieve target risk-levels defined using preliminary remediation goals (PRGs). PRGs were based on 1×10^{-5} cancer risk level and a hazard index of 1.0. This alternative would also remove all soil from the top two feet of the soil column with polychlorinated biphenyl (PCB) concentrations greater than 25 milligrams per kilogram (mg/kg) and would remove subsurface soil (to 20 feet depth) with PCB concentrations greater than 100 mg/kg as an added safety factor. Using safety factors (25 mg/kg and 100 mg/kg) in the cleanup will preclude higher confirmatory-sample concentrations from being diluted as sampling results are added to the Block E surface- and subsurface-soil data sets and representative exposure-point concentrations are recalculated.

Post-removal confirmation samples will be collected from the excavation bottoms and sidewalls before backfilling. Individual confirmation sampling results will be added to the Block E surface- and subsurface-soil data sets as input into the RRA to confirm that the recalculated 95% upper confidence limit (UCL) exposure-point concentrations continue to result in a cumulative residual-cancer-risk at or below 1×10^{-5} (i.e., a one-in-100,000 probability) and less than a hazard index of 1 (see Section 4). If this risk level is not met, additional soil will be removed beyond the proposed soil-removal limits until the risk management criteria are met. Soil excavated beyond the targeted subsurface excavation to produce the stable 1:1 slope excavation sidewall will be segregated, stockpiled, tested, and reused as backfill. Runoff from the stockpile will be captured by stormwater controls, such as wattles, and treated. Run-on will be minimized. If the soil contamination does not meet backfill requirements, the soil will be disposed of off-site and additional backfill material will be brought to the site.

Sampling in 2003 did not identify impacts to soil beneath the product pipeline, and total petroleum hydrocarbons (TPH) were not considered a significant contributor to risk when formulating the Block E soil remedial action. Confirmatory sampling will be conducted in the product pipeline excavation to verify removal of soil with TPH diesel-range organics (TPH-DRO) concentrations greater than the Maryland Department of the Environment (MDE) Oil Control Program (OCP) residential cleanup goal of 230 mg/kg. Confirmatory sampling will determine whether additional soil removal might be required from the product pipeline footprint until concentrations of TPH-DRO in the base and sidewall soil samples are confirmed to be below the MDE OCP residential cleanup goal.

Excavation in the southeastern area is expected to be entirely within the unsaturated zone, based on historical groundwater level measurements collected in this area, so no dewatering is expected to be needed there. If the groundwater table is unusually high, the water from the excavation will require management and disposal as a hazardous waste because trichloroethene (TCE) concentrations in the groundwater of that area has been determined to be a listed waste.

Asbestos-containing material (ACM) may be present as insulation on some sub-slab pipelines and sumps, and in ceramic tile and adhesive. If potential ACM is encountered, samples will be collected to determine asbestos content. ACM will be managed and disposed of according to National Emission Standards for Hazardous Air Pollutants (NESHAP), Occupational Health and Safety Administration (OSHA), and state regulations.

The product pipeline remediation is implemented under the OCP and is unrelated to the PCB cleanup. Clean closure of the pipeline will eliminate the need for land use controls (LUCs) related to the pipeline soil if industrial cleanup levels were used. Alternatively, if residential standards cannot be practicably achieved by further excavation under the product pipeline, then site closure will be pursued, in conjunction with the MDE OCP-inspector's approval, using LUCs to limit future access to remaining soil that exceeds these screening criteria. Additional excavation might also be necessary in the footprint of the excavated storm drains, based on confirmatory sampling

results for TPH-DRO, TPH gasoline-range organics, PCBs, and volatile organic compounds (VOCs).

As described in Appendix I, foundation slab, subgrade soil, and drain lines will be surveyed for possible radioactive residue from materials that might have historically been used at former Building D. All radioactive material identified during radiological surveys will be packaged, removed to a material accumulation area, sampled for offsite disposal facility waste acceptance criteria, and staged for offsite shipment.

Semiannual groundwater monitoring in several Block E wells (MW-43A, MW-103A, MW-103B, MW-113A, MW-114A, MW-123A, MW-124A, MW-124B, MW-126A, MW-127A, MW-127B, and MW-130A; see Figure 5-26) will continue for two years after completion of the remedial action, with analyses for PCBs (using Method 680), polycyclic aromatic hydrocarbons (PAHs), and VOCs, to ensure that Alternative 3 satisfies remedial action objectives (RAOs) in the long term. As shown on Table 6-1, contingencies might be activated based on monitoring results.

SECTION 7
PROPOSED REMEDIAL ACTIONS

This section presents the proposed remedial action for impacted Block E soil at the Middle River Complex (MRC). The proposed remedial alternative chosen for Block E (Alternative 3) would remove impacted soil in areas identified by residual-risk analysis (RRA) to reduce industrial and construction worker risk to achieve target risk levels developed using preliminary remedial goals (PRGs). The proposed remedial alternative would also remove soil with polychlorinated biphenyl (PCB) concentrations greater than 25 milligrams per kilogram (mg/kg) to two feet below soil surface, and remove subsurface soil having PCB concentrations greater than 100 mg/kg, as well as implement institutional controls. Figure 5-19 is a layout of the remedial action; a summary of the proposed remedial action components appears in this section. Figure 7-1 depicts the remedial action and many of the common elements to illustrate the overall activity and disturbance of the site. This proposed conceptual design might be altered during the detailed-design process, and in response to regulatory review, permitting requirements, and any additional information obtained before implementation. Note that although unsupported excavation walls were assumed in the development of this alternative, the sheet pile approach will be evaluated during the design and may still be implemented in the final design.

A final remedial action design will be developed following Maryland Department of the Environment (MDE) approval of this remedial action plan (RAP). The design will provide the final design-basis for the remedial actions, details regarding the areas and volumes of soil to be excavated, and the volume and type of fill material. The proposed action will also be submitted to the United States Environmental Protection Agency (USEPA) for review and approval as a risk-based disposal-approval application (RBDAA). The schedule for implementing the remedial action is in Section 9. The major components of the remedial action necessary to achieve a "No Further Action" letter are as follows:

- surveying slab, sub-slab soil, and drains for possible radioactive residue, followed by removal and disposal of radioactive material

- removal of existing soil piles overlying the concrete slab (most of this soil can be used as backfill)
- demolition and disposal of the concrete slab, footings, and pile caps, and leaving foundation piles in place. Piles exposed during excavation will be cut and removed, as well as other adjacent concrete and asphalt surfaces (uncontaminated concrete and asphalt can be recycled on-site)
- removal and disposal of most of the current stormwater system
- removal and disposal or recycling of the product pipeline
- removal of soil to allow industrial site use
- reconstruction of an acceptable stormwater management system to drain post-remediation surfaces and grading
- post-removal confirmation sampling and analysis
- characterization, transport, and off-site disposal of removed materials
- backfilling with clean backfill and re-grading
- site restoration
- two years of semiannual groundwater monitoring
- implementation of institutional controls

The sequence of activities will be developed and detailed in a work plan. Many of the components described above will occur concurrently. For example, after excavation of one area has been completed, excavation of a second area will begin while the first area is backfilled.

7.1 RADIOLOGICAL TESTING

Radiological surveys will be performed during the proposed remedial action to ensure that radiological materials or residual radiological contamination, if encountered, are properly removed and disposed of. Radiological surveys will also verify that no radioactive materials above release criterion remain, thereby releasing the site from post-remediation radiological restrictions. The following activities will support remediation activities (see Appendix I):

- work-area exposure surveys for personnel protection during demolition

- work-area radiation surveys for personnel protection during demolition
- work-area air monitoring for personnel protection during demolition
- contamination surveys of piping, concrete, soil, and debris to identify/segregate materials and determine disposal options
- building slab and foundation demolition
- soil removal
- final status survey after removal of building structure to verify that the site can be released with no restrictions
- contamination surveys on equipment and materials during decontamination activities and for unconditional release from the site
- report results from field activities

The subsurface soil beneath the Building D slab consists of imported backfill material and native soil graded during pre-construction site preparation. Hundreds of soil samples and soil cores have been screened and analyzed since 2013. All soil sample radioactive compound concentrations collected during field activities, except for two core borings (see Appendix I, Section 2.3.3), fall within the variable ranges of natural background concentrations.

Undisturbed soil samples were collected in Block F to generate a background reference-area value for a non-impacted area. However, the soil characteristics in Block F are decidedly different from those in Block E (undisturbed, undeveloped soil versus disturbed, developed soil), and the sampling results do not reflect the ranges found in Block E. Block E soil sampled to date, except for the two previously mentioned core borings, are representative of background concentrations in Block E. Table 2-1 of Appendix I presents the Block E background sample ranges. A radiological remediation plan detailing radiological survey procedures is in Appendix I.

7.2 SOIL PILE REMOVAL

The soil piles on the northern and western sides of the former Building D foundation were sampled during the remedial investigation, and the PRG for benzo(a)pyrene equivalents (BaPEq) was exceeded at five shallow soil locations. BaPEq-impacted soil will be excavated and disposed of off-site, and the balance of the soil piles will be used as backfill. The remaining soil will be used

as backfill if it meets the requirements of the Soil Management Plan for Blocks E and I (Tetra Tech, 2019b). A temporary retaining wall will be installed near the western end of the former building foundation to stabilize the Tilley Chemical Company property during soil-pile removal. A retaining wall is not needed along the northern side of the slab, because sufficient space is available to grade the slope to a stable configuration while removing soil from the slab.

7.3 CONCRETE AND FLOOR SLAB DEMOLITION

Although Building D was demolished in the early 1970s, the building's foundation and basement floor slab, as well as other concrete and an asphalt access roadway, remain in Block E. The floor slab consists of concrete slabs with ceramic tiles overlying the concrete in several locations. The concrete slab contains construction or expansion joints and cracking between and within the slabs.

All concrete in Block E (an estimated 24,000 tons) will be removed during the proposed remedial action. This quantity includes the entire former Building D floor slab, perimeter and internal footers, piles in excavations that must be cut off, and other concrete surrounding Block E. The work will progress in stages, such that after slab removal, soil excavation, and confirmation sampling in one area has been completed, backfilling will begin while slab removal and excavation begin in another area. This will minimize the area of impacted soil exposed to stormwater and reduce the volume of water to be treated.

The concrete slab will be removed in manageable sections using heavy equipment to facilitate radiological screening and sampling of the concrete and underlying floor drains. The concrete foundation will be visually surveyed for PCB staining and surveyed for radiological materials per Appendix I. All stained concrete will be segregated from non-impacted material, as will already tested concrete with elevated PCB concentrations. All concrete with radiological material concentrations above the *Atomic Energy Commission Regulatory Guide 1.86* levels for surface contamination for isotopic uranium (see Table 7-1) will be segregated from non-impacted material. Residual concrete and asphalt adjacent to the concrete slab will also be removed as part of removing the concrete foundation.

The floor drain system will be visually inspected to determine if it has been damaged. Radiation and contamination surveys of exposed areas of the drain system and surrounding soil will

determine if conditions are safe before proceeding to remove the next section of concrete. If an area of elevated radionuclide activity is found after slab removal, it will be covered and secured to prevent the spread of contamination until further investigation and, if necessary, remediation can be performed. These areas will be barricaded to prevent the entry of unauthorized personnel. This protocol will be repeated for each section of slab removed.

In areas where the slab has been removed, the floor drain system will be broken into manageable pieces using heavy equipment. Each piece of the floor drain system and surrounding soil will be surveyed under the supervision of a health physicist before other personnel enter the area. The results of the radiological survey will determine how materials will be packaged, removed, staged, and disposed of. Care will be taken to remove as little dirt as possible when materials such as concrete or floor drains are removed. If no radiological contamination above the limits in Table 7-1 is found, material will be removed and disposed of as nonradioactive waste. If concrete is not stained or contaminated by petroleum hydrocarbons, it will be broken up, temporarily stored, and recycled on-site as described in Section 7.8.

Radiological contamination in the underlying soil is not expected, provided the floor drain piping is removed in accordance with procedural guidance. However, unknown piping failures might have occurred in the past, so coverage surveys, as described in Appendix I, will be performed to monitor for this possibility. Possibly contaminated soil and debris exceeding Table 7-1 values will be removed, staged, and sampled for analysis, and, if necessary, disposed of as low-level radioactive material. This material will be bagged, wrapped, or containerized before being moved to the staging area, to prevent the spread of contamination during movement. Staging areas for these materials will be covered with disposable materials (e.g., tarps, plastic) before use and designated/barricaded as radiological areas until the material has been removed for disposal.

Monitoring wells within the footprints of the concrete removal areas will be abandoned prior the demolition activity. Monitoring wells outside of the concrete removal areas along with injection wells and piping associated with the groundwater treatment system in the southeastern area will be protected from damage.

7.4 CURRENT STORM SEWER SYSTEM AND PRODUCT PIPELINE REMOVAL AND DISPOSAL

The existing (but abandoned) product pipeline is a 1,815-foot-long, 2-inch-diameter pipe that runs underground from a former 500,000-gallon fuel oil aboveground storage tank (AST) previously located in Block E to the MRC power plant in Block I. Approximately 1,500 feet of the pipeline is in Block E, but approximately 200 feet have already been removed. The location of the pipeline running along the western and southern boundary of Block E is shown on Figure 5-25. Once the pipeline exits Block E, it runs through a tunnel that historically connected Building D with Building C in Block I. The underground portion of the product pipeline in Block E will be removed as part of the proposed remedial alternative under the oversight of an MDE Oil Control Program (OCP) inspector, and in compliance with *Code of Maryland Regulations* (COMAR) Title 26.10.

The current southern portion of the Block E storm-drain line impacted with PCBs, along with surrounding contaminated soil, will also be removed. Figure 5-25 shows the storm sewers that will be removed. During removal of the storm sewer along the eastern side, the groundwater treatment system discharge pipeline and electrical service must be protected. A stormwater management system, as described in Section 7.6, will be designed and constructed as part of the remediation program. Because the routes of the current stormwater channels and sewers will likely be used for the new stormwater management system (see Figure 7-1), potentially contaminated soil along channels will be replaced with at least six inches of clean backfill. After the existing storm sewers and soil are removed, the trench will first be filled with surface soil along each side of the trench, then backfilled to grade with clean soil.

7.5 EXCAVATION AND DEWATERING

Erosion and sedimentation controls specified in the grading plan (to be approved by the Baltimore County Soil Conservation District) will be installed and inspected by the county before excavation begins. The county will issue a grading permit upon approval of the installation. The excavation of Block E and the Chesapeake Park Plaza median can proceed once that, and all other permits associated with the project, have been issued. To meet risk-based industrial and construction worker criteria, approximately 22,000 cubic yards (cy) (approximately 1,700 truckloads) of soil in Block E have been identified for excavation and disposal (see Figure 5-19). Note that although

unsupported excavation walls were assumed in the development of this alternative, the sheet pile approach may still be implemented in the final design.

Block E soil with PCB concentrations greater than 50 mg/kg will be removed and disposed of at a Toxic Substances Control Act (TSCA)-permitted hazardous waste facility. The removal limits in this RAP were determined based on the review of extensive soil sampling results discussed in Section 2. The final limits of removal will be determined after post-removal confirmation sampling has been completed and the RRA has been rerun. Sediment accumulated in erosion- and sediment-control devices will be disposed of off-site, along with the removed soil. Erosion- and sediment-control devices will be described in the Block E remedial action design.

Subsurface soil removal areas will be dewatered to facilitate excavation and backfilling. Stormwater that flows into the excavations or contacts possibly impacted soil will also be collected. Excavated soil might also require dewatering. Dewatering liquid, sub-slab water, and other collected stormwater will be placed into portable holding tanks before on-site treatment with filtration and granular activated-carbon (GAC), and then discharged via a National Pollutant Discharge Elimination System (NPDES) permit. Discharge to a sanitary sewer will be evaluated further during the final design.

Solids trapped by filtration will be analyzed and, depending on the results, transported to an approved facility for disposal. GAC used to treat this dewatered liquid will also be characterized and disposed of appropriately. The treated water will be discharged to surface water through the MRC-permitted NPDES storm-drain and outfall system. Permits required for the proposed remedial action are described in Section 8.2.

7.6 STORMWATER MANAGEMENT SYSTEM

To achieve remedial action objective (RAO) No. 2, part of the proposed remedial alternative entails building a new stormwater management system to replace the existing Block E storm drains. A conceptual design for site grading and general stormwater conveyance has been prepared (see Appendix J), and a final stormwater study to assess site drainage will be performed before the final design. The existing storm drain system will be replaced with surface channels and pipelines (designed for use under remedied site conditions) to accommodate stormwater requirements

associated with a 100-year-storm with considerations given to higher intensity events, such as a 500-year-storm. Although most of the surface will be replaced by clean backfill, there are a few areas where potentially PCB-impacted soil on the surface will be exposed to stormwater in channels such that soil could be eroded and discharged. In those areas, at least six inches of soil below the channel will be replaced with clean backfill (see Figure 7-1). The new stormwater management system design will be included in the final remedial action design that will be developed following approval of this RAP. The conceptual design of the stormwater management system follows existing channels and storm sewer routes such that storm water will not be in contact with potentially impacted soil. If the final stormwater management system design uses different channel routes, then clean fill must be used for the channel routes, too.

7.7 CONFIRMATION SOIL SAMPLING

Post-removal confirmation samples will be collected from the excavation bases and the sidewalls of the soil removal areas before backfilling to confirm that recalculated 95% UCL exposure-point concentrations continue to result in a cumulative residual cancer risk at or below 1×10^{-5} and a hazard index less than 1 (see Section 5). The sidewall samples will be collected as composite samples. A five-point composite sample will be collected per each approximately 100-foot segment of sidewall. Base samples will be collected as five-point composite samples from every 100-square-foot base area.

Base and sidewall samples will be analyzed for PCBs using USEPA Method 8082A. Analyses for other contaminants, such as polycyclic aromatic hydrocarbons (PAHs) using USEPA Method 8270, and volatile organic compounds (VOCs) using USEPA Method 8260B, will be performed at locations where these contaminants are being remediated per the RRA. Confirmation samples collected from the storm-drain piping excavations will be collected in the same manner and analyzed for the same parameters. The composite sampling results will be used in an RRA recalculation to determine if RAO No. 1 has been achieved. If not, additional soil will be removed until the RAO has been met.

Post-removal confirmation samples will also be collected from the base and sidewalls of the product pipeline excavation and analyzed to verify that residual total-petroleum-hydrocarbon diesel-range organics (TPH-DRO) concentrations in remaining soil are less than the MDE OCP

residential-cleanup goal of 230 mg/kg. The compliance division of the MDE OCP will be notified of the planned pipeline removal 30 days before excavation. Confirmation sampling requirements and results could be subject to OCP review and approval, and such requirements would be set forth by OCP officials upon notification. Preliminary discussion with OCP staff suggests that base and sidewall confirmation soil samples will likely be required every 50 feet along the length of the pipe within Block E.

7.8 WASTE CHARACTERIZATION AND DISPOSAL

Before remedial activities begin, soil in the proposed excavation areas will be sampled and analyzed for waste disposal characterization at a minimum frequency of one sample per 500 cubic yards, or as required by the selected disposal facility. Sampling frequency might be increased depending on the volume of soil to be removed and waste disposal facility requirements. Samples will be analyzed by the toxicity characteristic leaching procedure (TCLP) and for parameters required by the waste disposal facility. For all required analyses except VOCs, composite samples consisting of three grab samples will be collected from each excavation area. Samples for VOC analysis will be collected as discrete samples from each excavation area before compositing.

Excavated soil will likely be directly loaded into trucks and transported for off-site disposal after waste characterization is complete and the waste disposal facility has accepted the waste. The transportation method to the disposal facility (e.g., truck, rail, or barge) will be determined during design. Soil identified during pre-design delineation sampling as having PCB contamination greater than 50 mg/kg will be disposed of at a TSCA-regulated facility approved by Lockheed Martin. The remaining removed soil will be disposed of as nonhazardous waste at an approved Subtitle D landfill or recycling facility approved by Lockheed Martin. Approximately 33,000 tons of soil, of which 30,000 tons will be disposed of at a TSCA-regulated facility, will be excavated, directly loaded at a rate of approximately 20 tons per truck and transported to the selected facilities during this remedial action. Approximately 1,700 truckloads (truck trips) will likely be required to remove contaminated soil during the remedial action.

Approximately 24,000 tons of concrete will be removed and disposed of offsite or recycled on-site as part of the selected remedy. Following radiological testing, concrete will be disposed of or recycled as follows:

- If contaminated, directly loaded and transported to a selected facility as follows: Concrete with PCB concentrations greater than 50 mg/kg would be disposed of at a TSCA-approved facility (approximately 1,000 tons or 50 truckloads). Concrete with PCB concentrations less than 50 mg/kg or unsuitable for recycling (for example, due to staining) would be disposed of at a nonhazardous waste landfill (approximately 4,000 tons or 200 truckloads).

- If uncontaminated, broken up on-site with crushing equipment that can cut reinforcing steel and wire mesh and used on-site as backfill (approximately 19,000 tons). Alternatively, the concrete would be broken up on-site and transported to a selected local recycling facility.

Current cost estimates are based on uncontaminated concrete being broken up and recycled as backfill on-site.

Air quality during soil and concrete handling would be evaluated using a combination of direct observation and perimeter sampling/monitoring stations. Water sprays would be used to control dust.

Trucks will be loaded continuously during working hours, anticipated to be 10 hours per day and five days per week. The number of trucks operating at the site might vary depending on availability. All trucks will be decontaminated (e.g., tires washed), screened for radioactivity, affixed with appropriate signage, loads secured with tarps, and truck safety-systems checked (e.g., brakes, signal lights, etc.) before leaving the site. Approximately two to three trucks per hour could be filled using direct-load techniques. Storm drain piping, concrete, steel, and other construction/demolition materials resulting from the removal of the former structure's foundations will be cleaned/decontaminated (as appropriate) and subsequently either recycled on-site or disposed of at an off-site facility permitted to accept such materials. Trucks will exit the site directly onto Chesapeake Park Plaza and follow a route similar to that used in the sediment remediation project. Details concerning the trucking route will be finalized during the remedial design. Peak construction hours and planned trucking routes would be set to minimize traffic and noise.

7.9 BACKFILLING

Removal areas will be backfilled after completion of post-removal confirmation sampling and excavation dewatering. Areas where the concrete has been removed will also be backfilled to the original grade. Additional fill over the original grade will be needed for final grading for

stormwater management. Clean backfill soil will be obtained primarily from an off-site borrow source and will be similar in grain size to the removed soil, as appropriate. The estimated quantity of backfill is 81,000 tons, which will be offset by on-site recycling of concrete as backfill, so a total of 60,000 tons (3,000 truckloads) of backfill brought to the site. The portions of soil piles not impacted by BaPEq will be used as backfill, if they meet the requirements of the Soil Management Plan for Blocks E and I (Tetra Tech, 2019b). Other materials, such as crushed stone, might also be used as backfill. Backfill material-acceptance criteria are in Table 7-2.

The off-site borrow source material will be evaluated according to the Soil Management Plan for Blocks E and I (Tetra Tech, 2019b). The off-site borrow source will be identified, and its environmental and geologic documentation will be obtained. The environmental and geotechnical properties of the material will be evaluated to determine its suitability for use. If the borrow source is judged acceptable, soil samples will then be obtained and analyzed for chemicals of concern (COC) using the methods listed in Table 7-2.

The minimum sampling frequency will be as recommended in the MDE clean-fill document and based on the size (i.e., area and volume) of the borrow source. Constituents detected in samples will be compared to MDE cleanup levels, to eastern-region anticipated typical concentrations (ATCs) (MDE, 2008), or to other MDE-approved risk-based concentrations. The off-site borrow source will have to be approved by MDE before transporting any backfill material from it onto the site.

Backfill material will be compacted to at least 90% of its maximum dry density, as determined by the standard proctor test using the ASTM International, Inc. (ASTM) Method D698-12 and/or American Association of State Highway and Transportation Officials (AASHTO) specification T-99. As noted in Section 7.3, the work will progress in stages, such that after slab removal, soil excavation, and confirmation sampling in one area has been completed, backfilling will begin while slab removal and excavation begin in another area. This will minimize the area of impacted soil exposed to stormwater and reduce the volume of water to be treated. Runoff from contaminated areas will be captured and treated. A combination of collection sumps and the excavations would be used per county requirements.

7.10 RESTORATION

The top six inches of backfill in areas to be restored with vegetation, which includes areas where contaminated soil has been excavated, and where the foundation, and other concrete roads and paved areas have been removed, will be medium-textured loam suitable for establishing vegetation (i.e., topsoil). The backfilled and regraded areas, along with other areas disturbed during implementation of the remedial action, will be restored/stabilized using permanent vegetative stabilization practices. Clean backfill (at least six inches) will be placed in the bottoms of storm water channels to prevent erosion of potentially PCB-impacted soil by the stormwater flowing through the channel. After final grading, vegetative restoration will consist of surface preparation, fertilizing, seeding with grass, and mulching. A crushed stone road will be built in the southeastern corner to provide access to the groundwater treatment systems. A conceptual design for the final grading is shown in Appendix J. Complete details on the restoration procedures, erosion and sediment controls, and final site layout will be included in the Block E remedial action design that will be prepared before implementation.

7.11 GROUNDWATER MONITORING

A groundwater monitoring plan to evaluate the effects of the soil removal on the groundwater will be developed during the design phase. This plan will include sample locations, analyses, sampling frequency, and a set of environmental criteria metrics for comparison of the results. These results will also be used to establish that concentrations are stable or decreasing. Tentatively, two years of semiannual groundwater monitoring will be conducted in 12 downgradient Block E wells to confirm attainment of RAO No. 3 by confirming that PCB and 1,2,4-trichlorobenzene (1,2,4-TCB) concentrations in groundwater are not increasing after the remedial action has been implemented. Groundwater monitoring wells (MW-43A, MW-103A, MW-103B, MW-113A, MW-114A, MW-123A, MW-124A, MW-124B, MW-126A, MW-127A, MW-127B, and MW-130A; see Figure 5-26) will be sampled each spring during the annual MRC groundwater monitoring program, and during an additional semiannual event each fall. Groundwater samples will be analyzed by an off-site laboratory for PCBs and 1,2,4-TCB using USEPA SW-846 Method 680 and USEPA SW-846 Method 8260B, respectively.

7.12 INSTITUTIONAL CONTROLS

MDE will document institutional controls applicable to Block E in the "No Further Action" letter that will be issued once the three RAOs have been met. The environmental covenants defined in the "No Further Action" letter will be filed in local land use records and will pass to subsequent property owners as part of the deed documentation. MDE regards all institutional controls as existing in perpetuity unless the related environmental covenants are eliminated or modified by mutual consent of the stakeholders. As part of the "No Further Action" letter and supporting documentation, MDE will present certain environmental covenants that will give stakeholders legal standing to enforce them.

MDE will determine final disposition of any institutional controls. Institutional controls will typically apply to the entire tax block, not just to smaller portions of the block, as to be agreed upon by MDE and Lockheed Martin Corporation (Lockheed Martin). Examples of institutional controls might include:

- prohibitions on using groundwater beneath the property for any purpose
- notification and handling requirements for soil during future excavations
- restrictions on use of the property for other than industrial purposes

7.13 ENVIRONMENTAL FOOTPRINT CONSIDERATIONS

Measures identified in the *SiteWise*™ evaluation (see Appendix L) that might reduce the environmental footprint of the alternatives are listed below:

- Using alternative modes of transportation (if possible) when transporting waste to disposal facilities.
- Optimizing the amount of soil needed for backfill, as this is one of the main drivers of sustainability.
- Optimizing the schedule to transport materials to the site in the best way possible.
- Reducing the environmental footprint, particularly air emissions, for all alternatives through the possible use of emission control measures such as alternate fuel sources (e.g., biodiesel), equipment exhaust controls (e.g., diesel emissions control), and equipment idle reduction.

- Optimizing the number of samples analyzed to characterize soil for disposal and quality.

- Reducing vehicle mileage thereby reducing worker risk, as well as energy use and emissions. Encouraging site workers to carpool daily to the site to reduce total vehicle mileage.

SECTION 8
PERMITS AND NOTIFICATIONS

This section describes the permits that will be required for the proposed remedial actions and the required notifications if unexpected conditions are encountered during implementation of this remedial action plan (RAP).

8.1 PERMITS

Lockheed Martin Corporation (Lockheed Martin) will meet all federal, state, and local permitting requirements for the proposed soil remedial action described in Section 7. Permitting requirements for the proposed remedial action relating to soil and off-site disposal will be subject to the soil-management requirements of the Maryland Department of the Environment (MDE) and the Baltimore County Department of Environmental Protection and Natural Resources. Appendix N contains a list of permit requirements, with contact information and review periods. Permits potentially required to implement the remedial action include the following:

- Although not strictly a permit, a Toxic Substances Control Act (TSCA) "Risk-Based Disposal Approval Application" must be submitted to the United States Environmental Protection Agency (USEPA). The application must be approved by USEPA before the work can begin.

- A Baltimore County grading permit is required for any land disturbance and grading that disturbs more than 5,000 square feet, or more than 100 cubic yards, of fill material. Grading plans will be submitted to Baltimore County for review and approval.

- A Baltimore County Department of Public Works Utility Cut permit, which is required for any work in a public right-of-way, will be needed to replace the storm sewer.

- An erosion- and sediment-control plan will be submitted to the Baltimore County Soil Conservation District (BCSCD), prepared in accordance with the *Maryland Standards and Specifications for Soil Erosion- and Sediment-Control* (MDE, 2011) and the *Baltimore County Urban Policy and Guidelines Manual* (BCSCD, 1999). The BCSCD review of erosion- and sediment-control plans will be coordinated with and incorporated into the Baltimore County review of the stormwater-management and grading plans.

- No critical-area resources are within Block E, so a waiver request for critical-area requirements for Block E work will be submitted to the Baltimore County Environmental Impact Review Department. A waiver is expected to be granted. The final total ground disturbance exceeds one acre, so a "Notice of Intent" application for a "Construction General Permit" for stormwater associated with construction will have to be submitted to MDE, along with an erosion- and sediment-control plan to be approved by the Baltimore County Soil Conservation District. Work within the tidal buffer will be identified and mitigated, as needed.

- The Maryland Heritage Trust will conduct a Section 106 National Historic Preservation Act-project review.

- The project will also be reviewed for potential impacts to listed species and critical/essential fish habitat according to guidelines from the Maryland Department of Natural Resources.

- A National Pollutant Discharge Elimination System (NPDES) permit and/or permit modification will be submitted to USEPA for the relocation and reconstruction of the Block E storm-drain system, and for excavation dewatering, if the extracted groundwater from subsurface soil excavation is to be discharged through the Middle River Complex (MRC) storm-drain and outfall system. Potentially contaminated runoff that enters excavations will also be collected and treated before discharge. Alternately, a permit could be secured from Baltimore County approving discharge to the sanitary sewer.

- A "Water Well Abandonment-Sealing Report" must be completed and submitted for each abandoned monitoring well. An "Application for Permit to Drill Well" form must be prepared and submitted prior to installing each new monitoring well, and after completion, a "Well Completion Report" is prepared and submitted for each well. These forms are submitted to the County and MDE.

8.2 NOTIFICATIONS

Lockheed Martin will follow appropriate MDE and USEPA notification requirements regarding previously undiscovered contamination, changes in the RAP schedule, and citations from regulators related to health and safety practices associated with implementation of the proposed remedial action and will be promptly notified of any discharges to the environment. MDE and USEPA will be notified prior to the start of significant field activities per the final work plan and schedule. LMC Properties, Inc. (LMCPI) will be kept informed of work progress and schedule. Potable water will be obtained at locations approved by LMCPI.

SECTION 9
IMPLEMENTATION SCHEDULE

The projected events sequence for this project, including the expected schedule for completing various milestones, appears below. All dates below are estimated and subject to change:

1) submit this remedial action plan (RAP) to the Maryland Department of the Environment (MDE) (and United States Environmental Protection Agency [USEPA] for informational purposes) (March 2019)

2) submit draft risk-based disposal approval application (RBDAA) to USEPA (and to MDE for informational purposes) (March 2019)

3) MDE review and approval of RAP (October 2019)

4) public review and comment of RAP (November 2019 to December 2019)

5) obtain required permits or variances (November 2019 to April 2021)

6) design remedial action (September 2019 to August 2020)

7) submit 100% design to MDE and USEPA (August 2020)

8) submit final RBDAA to USEPA (October 2020)

9) MDE approval of design (October 2020)

10) USEPA approval of RBDAA (April 2021)

11) implement the remedial action (begin April 2021)

12) complete remedial action implementation (December 2021)

13) complete post-remedial-action monitoring and documentation (2023)

14) request a "No Further Action" letter (2023)

Sample ID (Sample depth in ft bgs)
Parameter Result in mg/kg

All sample results shown in milligrams per kilogram (mg/kg).
All sample locations are plotted; however, some without exceedances may be obscured for illustrative purposes.
Aroclor 1260 (and Total Aroclor) Risk-based PRG for Block E Subsurface Soil is 58 mg/kg. Aroclor 1254 Risk-based PRG for Block E Subsurface soil is 7 mg/kg.
* Deeper sample(s) at this location were analyzed and had no exceedances.
PCB = Polychlorinated biphenyl.
PRG = Preliminary Remediation Goal.
J = Estimated value.
(DUP) = Duplicate sample.

Result for deepest soil sample with PRG exceedance is shown for the purpose of delineating PCB subsurface extent. Additional samples have been collected in these borings and shallower results/exceedances are listed in Appendix D. It is assumed soils overlying and including the deepest exceedance will need to be addressed through future response actions.

2017 aerial photograph provided by the State of Maryland.

- Surface Soil Replacement to Meet RAO No. 2, per Numbered Notes
- 2 See Numbered Notes

2017 aerial photograph provided by the State of Maryland.

Numbered Notes:
1) After removal of sewer and soil below sewer, use surface soil adjacent to trench to begin backfilling, then top off excavation with clean backfill (at least 6 inches).
2) Replace bottom of channel wth at least 6 inches of clean soil.
3) Excavate additional soil as needed and replace with clean backfill so that there is at least 6 inches of clean soil at the bottom of the channel.
4) Excavate additional soil as needed and replace with clean backfill so that there is at least 6 inches of clean soil at the bottom of the channel (lower portions of proposed channels).
5) Replace soil in median with at least 1 foot of clean soil.

Table 4-1

Preliminary Remediation Goals (PRGs) for Industrial and Construction Workers—Block E Soil Lockheed Martin Middle River Complex, Middle River, Maryland

Chemical of Concern	Surface soil (mg/kg)	Risk-based basis for PRG	Subsurface soil (mg/kg)	Risk-based basis for PRG
Aroclor 1254	7[(1)]	Construction worker; hazard index = 1	7 [(2)]	Construction worker; hazard index = 1
Total PCBs; Aroclor 1260	10[(3)]	Industrial worker; 1×10^{-5} cancer risk level	58[(3)]	Construction worker; 1×10^{-5} cancer risk level
BaPEq	2.9[(3)]	Industrial worker; 1×10^{-5} cancer risk level	10[(2)]	Construction worker; hazard index = 1
TCE	3.9[(1)]	Construction worker; hazard index = 1	3.9[(2)]	Construction worker; hazard index = 1
1,2,4-TCB	330[(1)]	Industrial worker; hazard index = 1	530[(2)]	Construction worker; hazard index = 1

Notes:

[(1)]Lowest value from cancer and non-cancer based PRGs calculated for industrial and construction workers.

[(2)]Lowest value from cancer and non-cancer based PRGs calculated for construction workers.

[(3)]The cancer-risk-based PRGs for these chemicals were adjusted to assure that the cumulative cancer risk resulting from exposure to both total PCBs and BaPEq does not exceed 1×10^{-5}.

BaPEq = benzo(a)pyrene equivalents
mg/kg = milligram(s) per kilogram
PRGs = preliminary remedial goal
Total PCBs = total polychlorinated biphenyls (e.g., the sum of Aroclor 1254 and 1260).
TCE = trichloroethene
1,2,4-TCB = 1,2,4-trichlorobenzene

Table 4-2

Summary of Selected Chemicals of Concern for Block E Soil Remedial Action Plan Lockheed Martin Middle River Complex, Middle River, Maryland

Receptor	Location	Environmental medium	Cancer risk drivers	Noncancer risk drivers	Reference
Industrial workers, Construction workers	All Block E soil	Surface soil 0–2'	Aroclor 1260, BaPEq	1,2,4-TCB, Aroclor 1254	Tax Block HHRA Tetra Tech 2012
Construction workers	Subsurface soil, excluding other Sub-Areas	Subsurface soil 2–20'	No COC	No COC	Table B-2 RRA Attachment B
	Transformer Room #2 Sub-area	Subsurface soil 2–20'	Aroclor 1260	No COC	Table B-3 RRA Attachment B
	Transformer Room #3 Sub-area	Subsurface soil 2–20'	Aroclor 1260	1,2,4-TCB	Table B-4 RRA Attachment B
	Transformer Room #4 Sub-area	Subsurface soil 2–20'	Aroclor 1254, Aroclor 1260, BaPEq	1,2,4-TCB, Aroclor 1254	Table B-5 RRA Attachment B
	Southeast Sub-area	Subsurface soil 2–20'	Aroclor 1254, TCE	Aroclor 1254, TCE	Table B-6 RRA Attachment B

Notes:

1,2,4-TCB = 1,2,4-trichlorobenzene
BaPEq = benzo(a)pyrene equivalents
COC = chemical(s) of concern
HHRA = human health risk assessment
RRA = residual risk analysis
TCE = trichloroethene

State				
Cleanup Standards for Soil and Groundwater	Maryland Annotated Code 7‑508	To be considered	This guidance document presents the approach and supporting documentation used to develop numeric cleanup standards for hazardous substances in soil and groundwater in the State of Maryland.	These non-promulgated standards may be considered for use in determining cleanup goals for soil in the absence of site-specific risk-based criteria.
Federal				
None				

Table 5-2

Location-Specific Applicable or Relevant and Appropriate Requirements
Block E Soil Remedial Action Plan
Lockheed Martin Corporation Middle River Complex,
Middle River, Maryland

Requirement	Citation	Status	Synopsis	Evaluation/Action to be Taken
Federal				
Endangered Species Act Regulations	50 CFR Parts 81, 225, and 402	applicable	This act requires federal agencies to take action to avoid jeopardizing the continued existence of federally listed endangered or threatened species.	If a site investigation or remediation could potentially affect an endangered species or their habitat, these regulations would apply. (There have been no endangered species or their habitat identified at the MRC.)
Historic Sites Act Regulations	36 CFR Part 62	applicable	Requires federal agencies to consider to existence and location of landmarks on the National Registry of Natural Landmarks to avoid undesirable impacts on such landmarks.	The existence of national landmarks will be identified prior to remedial activities on site including remedial investigations. (No national landmarks have been identified at the MRC.)
State				
Nongame and Endangered Species Conservation Act	Annotated Code of Maryland 10-2A-01; COMAR 08.03.08 and 08.02.12.	applicable	Requires state agencies to use their authority to maintain and enhance nongame wildlife and endangered species populations.	If a site investigation or remediation could potentially affect an endangered species or their habitat, these regulations would apply. (No endangered species or habitats have been identified at the MRC.)
Division of Historical and Cultural Programs	Annotated Code of Maryland 5A	applicable	The Maryland Historic Trust formed in 1961 to preserve, protect, and enhance districts, sites, buildings, structures, and objects significant in the prehistory, history, upland and underwater archeology, architecture, engineering, and culture of Maryland.	The existence of Maryland historic sites would be identified prior to remedial activities on site including remedial investigations. (No historic sites have been identified at the MRC.)

CFR – Code of Federal Regulations
COMAR – Code of Maryland Regulations
MRC – Middle River Complex

Table 5-3

Action-Specific Applicable or Relevant and Appropriate Requirements
Block E Soil Remedial Action Plan
Lockheed Martin Corporation Middle River Complex
Middle River, Maryland

Requirement	Citation	Status	Synopsis	Evaluation/Action to be Taken
Federal				
Toxic Substance Control Act	15 U.S.C. 2605; 40 CFR 761.60, .61, and .70	applicable	Management and disposal of materials containing polychlorinated biphenyls (PCBs).	Toxic Substance Control Act is considered for disposal of soils with PCB concentrations greater than 50 milligrams per kilogram.
Resource Conservation and Recovery Act (RCRA) Regulations, Identification and Listing of Hazardous Wastes	40 Code of Federal Regulations (CFR) Part 261 Subparts A, B, C, and D	applicable	Defines the listed and characteristic hazardous wastes subject to RCRA. Appendix II contains the toxicity characteristic leaching procedure (TCLP).	These regulations would apply when determining whether groundwater and soil cuttings from wells are hazardous, either by being listed, or by exhibiting a hazardous characteristic.
RCRA Regulations, Standards Applicable to Generators	40 CFR 262, Subparts A, B, C, and D	applicable	Establishes manifesting, pre transport, and recordkeeping requirements for hazardous waste.	These regulations would apply to sampling waste, if determined to be hazardous.
RCRA Regulations, Use and Management of Containers	40 CFR Part 264, Subpart I	applicable	Sets standards for the storage of containers of hazardous waste.	This requirement would apply if a response action alternative involves the storage of a hazardous waste (i.e., purge water) in containers prior to treatment or disposal. Maryland is a delegated RCRA state, so refer to Maryland regulations.
Clean Water Act NPDES Regulations (Stormwater Discharge)	40 CFR 122.26	applicable	Requires implementation of erosion and sediment control best management practices and permitting of storm water discharges during construction activities.	Response action has to implement best management practices for erosion and sediment control to minimize runoff and migration of soils and sediments and meet storm water discharge requirements for construction activities.
Clean Water Act NPDES Regulations (Discharge during implementation of the Remedial Alternative)	40 CFR 122.41, 122.44, and 122.45	applicable	Requirement of an NPDES permit if groundwater from dewatering requires treatment prior discharge to surface water.	If water is generated from dewatering excavations, then water would be treated prior to discharge to surface water.

Table 5-3

Action-Specific Applicable or Relevant and Appropriate Requirements
Block E Soil Remedial Action Plan
Lockheed Martin Corporation Middle River Complex
Middle River, Maryland

Requirement	Citation	Status	Synopsis	Evaluation/Action to be Taken
Federal (Continued)				
Migratory Bird Treaty Act	16 USC 703-711	applicable	Protects migratory birds and their nests.	Proposed response action will not kill migratory birds or destroy their nests and eggs.
State				
Maryland Hazardous Waste Management System – Identification	Code of Maryland Regulations (COMAR) 26.13.02	applicable	Identifies definitions and methods of identification of hazardous waste.	These regulations would apply when determining whether groundwater, and soil cuttings from wells are hazardous, either by being listed, or by exhibiting a hazardous characteristic.
Maryland Hazardous Waste Management System – Generators	COMAR 26.13.03	applicable	Establishes manifesting, pre-transport, and recordkeeping requirements for hazardous waste.	These regulations would apply to sampling waste, if determined to be hazardous.
Maryland General Permit for Construction Activity	COMAR 26.17.01 and -.02	applicable	Establishes requirements for stormwater management and erosion and sediment control at construction sites.	Response actions involving excavation would require submittal of an erosion and sediment control plan and a stormwater management plan during land disturbance in accordance with Maryland Stormwater Design Manual (Volume I & II), latest revision.
Air Quality – Particulate Matter	COMAR 26.11.06.03D	applicable	During construction, reasonable precautions to prevent particulate matter from becoming airborne must be taken.	Fugitive dust generated during soil management will be controlled, for example by the use of water sprays.
Maryland Pollutant Discharge Elimination System: Water Quality, Discharge Limitations and Discharge Permit Limits	COMAR 26.08.02, 26.08.03, and, 26.08.04.02.	applicable	These standards govern discharge of water into surface waters.	Groundwater from dewatering would be treated as required prior to discharge to surface water.

Table 5-3

Action-Specific Applicable or Relevant and Appropriate Requirements
Block E Soil Remedial Action Plan
Lockheed Martin Corporation Middle River Complex
Middle River, Maryland

Requirement	Citation	Status	Synopsis	Evaluation/Action to be Taken
State (Continued)				
Water Pollution Surface Water Quality Criteria	COMAR 26.08.02.03	applicable	Establish minimum standards for surface water quality for each designated use. Standards are available for the protection of human health and the protection of aquatic life.	Considered for determining effluent criteria for alternatives that involve discharges to surface water.
Local				
Baltimore County Grading Permit	Not Available	applicable	A grading permit is required for grading or land disturbance greater than 5,000 square feet.	The permit will be needed for the large excavation activity

ARARs – applicable or relevant and appropriate requirements
CAA – Clean Air Act
CERCLA – Comprehensive Environmental Response Compensation, and Liability Act
CFR – Code of Federal Regulations
COMAR – Code of Maryland Regulations
LDRs – land disposal restrictions
MDE – Maryland Department of the Environment
NAAQS – National Ambient Air Quality Standards
OSHA – Occupational Safety and Health Act
PCB – polychlorinated biphenyl
RCRA – Resource Conservation and Recovery Act
TCLP – toxicity characteristic leaching procedure
TSDF – treatment, storage, and disposal facility
USC – United States Code

Table 5-4

Remedial Action Objectives and General Response Actions
Block E Soil Remedial Action Plan
Lockheed Martin Middle River Complex, Middle River, Maryland

Remedial Action Objectives	General Response Actions					
	No Action	Institutional Controls	Containment	Treatment – *in situ* or *ex situ*	Removal	Disposal (off-site)
Reduce site-related chemicals of concern (COC) in Block E soils to not exceed a cumulative 1×10^{-5} human health cancer-risk level and to less than a cumulative non-carcinogenic hazard index of 1 for industrial workers and construction workers.		X	X	X	X	X
Prevent transfer of polychlorinated biphenyls to the extent practicable from surface soil and storm drains to discharged stormwater at concentrations that would impact the sediment remedy.			X	X	X	X
Prevent to the extent practicable leaching of PCBs and 1,2,4-trichlorobenzene from soil to groundwater at concentrations that would impact surface water concentrations.			X	X	X	X

COC - chemical(s) of concern

HI - hazard index

PCBs - polychlorinated biphenyls

Table 5-5

Results of Preliminary Technology Screening
Block E Soil Remedial Action Plan
Middle River Complex, Middle River, Maryland

General Response Action	Remedial Action Technology	Process Option	Description	Quantitative Screening Based on Criteria Below					Results		
				Effectiveness (Primary)			Implementability	Relative Cost			
				Effectiveness in Handling Volumes of Impacted Media	Impacts during Implementation	Reliability			Screening Comment	Retain	Eliminate
No Action	None	Not Applicable	No activities conducted in the block to address contamination.	Not Applicable	Not Applicable	Not Reliable	Easily Implementable	Low Cost	Retained for baseline comparison	✓	
Limited Action	Land Use Controls	Site Use Restrictions	Administrative action using excavation permits and other land use prohibitions to restrict future site activities.	Effective	No Impacts During Implementation	Technology is reliable provided land use restrictions and, excavation restrictions are well documented and implemented.	Easily Implementable	Low Cost	This technology would leave soil contaminants in place but will lower risk, and will meet remedial action objectives (RAOs) provided it is used with another treatment technology. Erosion would transport surface soil to sediment.	✓	
Containment	Capping	Soil Cover/Cap that meets TSCA requirements	Various types of capping systems to meet the TSCA requirements for to prevent or minimize human exposure, infiltration of water, and erosion.	Effective in containing and covering impacted soils.	Large quantities of material for capping will have to be transported to the block.	Reliable	Easily implementable	Moderate Cost	This technology will meet the remedial objectives of eliminating risk pathways and transport to sediment, but does not affect mobility of PCBs already in the groundwater, and will not reduce volume and toxicity of contaminants.	✓	

Table 5-5

Results of Preliminary Technology Screening
Block E Soil Remedial Action Plan
Middle River Complex, Middle River, Maryland

General Response Action	Remedial Action Technology	Process Option	Description	Quantitative Screening Based on Criteria Below					Results		
				Effectiveness (Primary)			Implementability	Relative Cost			
				Effectiveness in Handling Volumes of Impacted Media	Impacts during Implementation	Reliability			Screening Comment	Retain	Eliminate
In Situ Treatment	Physical/ Chemical	Vitrification	*In situ* vitrification (ISV) is an *in situ* solidification/stabilization technology which uses an electric current to melt soil or other earthen materials at extremely high temperatures (1,600 to 2,000 °C or 2,900 to 3,650 °F) and thereby immobilize most inorganics and destroy organic pollutants by pyrolysis. Inorganic pollutants are incorporated within the vitrified glass and crystalline mass. Water vapor and organic pyrolysis combustion products are captured in a hood, which draws the contaminants into an off-gas treatment system that removes particulates and other pollutants from the gas. The vitrification product is a chemically stable, leach-resistant, glass and crystalline material similar to obsidian or basalt rock.	Not effective due to shallow groundwater table and large quantities of energy required.	ISV is a high-temperature thermal process; therefore, off-gas collection (e.g., off-gas collection hood) and treatment are required.	Reliable	Requires large amounts of energy	High Cost	The solidified materials in soils may hinder other groundwater treatment technologies. Future land use may be limited.		✓
		Soil mixing with nano-scale zero valent iron (ZVI) or emulsified nano-scale ZVI	Remediation with zero valent iron (Fe^0) degrades recalcitrant chemicals by reductive processes. ZVI has been used in the permeable reactive barrier (PRB) to treat halogenated VOCs and heavy metals. Nano-scale ZVI was developed to further enhance its effectiveness and the clean-up time. This technology involves mixing soil with nano-scale ZVI and an environmentally benign surfactant (food grade) or emulsifier such as vegetable oil.	This technology is potentially applicable to PCBs. The pH increase and ORP decrease would be beneficial for accelerated reductive biodegradation. The nano-scale ZVI remains reactive in soils for extended periods of time (> 4-8 weeks).	Large quantities of soils must be processed. Large quantity of ZVI may have to be transported to the site.	Remediation with ZVI is an emerging technology for PCBs.	Requires a bench-scale and/or a pilot-scale testing prior to implementation. ZVI solids will be difficult to mix into clay and clayey soils.	High Cost	Eliminated. High Cost, uncertain reliability, and concerns with introducing nano-particles into the environment.		✓
		Surfactant enhanced *in situ* chemical oxidation	This technology uses the chemical oxidants, typically including peroxide, ozone, persulfate, and permanganate to destroy organic contaminants. This technology has been further enhanced using surfactants to solubilizes the COC in soils and subsequently oxidize them. Plant oil-based cosolvents are commonly used as a surfactant. Oxidant delivery systems often employ vertical or horizontal wells.	Effective. Among commonly used oxidants, peroxone (ozone/peroxide) is known to destroy all organic COC at the site, including PAHs and PCBs, and possibly other chlorinated compounds.	Requires large quantities of hazardous chemicals; health and safety concern.	Reliable	Requires a bench-scale and/or a pilot-scale testing prior to implementation. Clay and clayey soils will be difficult to mix and contact with reagents.	High Cost	Can potentially mobilize PCBs. Eliminated due to high costs and health and safety concerns.		✓
		Electrokinetic separation	The electrokinetic remediation (ER) process relies on application of a low-intensity direct current through the soil between ceramic electrodes that are divided into a cathode array and an anode array. Metals ions move toward the cathode, whereas anions move toward the anode. The current creates an acid front, which helps mobilize sorbed metals for transport to the collection system at the cathode. This technology is applicable in low permeability soils.	This technology can address both metals and organic contaminants, but few applications with PCBs. Enhanced removal mechanism provides transport of metals toward the polarized electrodes for subsequent removal.	Will require the use of other technologies (e.g. pumping water with mobilized contaminants, followed by *ex situ* treatment)	Not reliable since little known about effectiveness of technology in commercial applications.	Significant challenges. Mobilized inorganic contaminants in groundwater will have to be extracted (pump and treat)	High Cost	There have been few, if any, commercial applications of electrokinetic remediation in the United States.		✓

Table 5-5

Results of Preliminary Technology Screening
Block E Soil Remedial Action Plan
Middle River Complex, Middle River, Maryland

General Response Action	Remedial Action Technology	Process Option	Description	Quantitative Screening Based on Criteria Below					Results		
				Effectiveness (Primary)			Implementability	Relative Cost	Screening Comment	Retain	Eliminate
				Effectiveness in Handling Volumes of Impacted Media	Impacts during Implementation	Reliability					
In Situ Treatment (continued)	Physical/ Chemical (continued)	Soil flushing	*In situ* flushing is accomplished by passing the extraction fluid (e.g., surfactants) through in-place soils using an injection or infiltration process.	This technology can be used to extract inorganics in soils and possibly organics such as PAHs.	A large quantity of surfactant may have to be transported to the site, and large volumes of extraction fluid must be recovered	There has been little commercial success with this technology. Not reliable since it mobilizes contaminants and the extraction fluid has to be recovered to recover contaminants of concern (COC).	Requires a bench-scale and/or a pilot-scale testing prior to implementation. Distribution of fluid through clay and clayey soil will be difficult. Groundwater at the site is shallow which could cause mobilized COC to impact the surface water near the site. Will require precise control of the flushing to recover all the surfactant and mobilized COC.	High Cost	This technology has had little commercial success; technology is not reliable because it mobilizes contaminants and the extraction fluid has to be recovered to recover COC. Eliminated.		✓
		Soil vapor extraction (SVE)	Vacuum is applied through extraction wells to create a pressure/concentration gradient that induces gas-phase volatiles to diffuse through soil to extraction wells. The process must include a system for handling off-gases. This technology also is known as *in situ* soil venting, *in situ* volatilization, enhanced volatilization, or soil vacuum extraction.	This technology is typically applicable to VOCs and not PCBs and PAHs since they are not volatile. Would not be effective in the saturated zone.	No major impacts, will require installation of SVE wells and vapor collection piping network.	Reliable when applied to VOCs in the vadose zone.	Can be easily implemented, but low permeability soils would require a high density of wells.	Moderate Cost	Not effective for PCBs and PAHs. Eliminated.		✓
		Thermally enhanced SVE – *in situ* thermal desorption	Thermally enhanced SVE is a technology that uses electrical resistance to increase the volatilization rate of VOCs and SVOCs. Electromagnetic/radio frequency heating, hot air, or steam injection may also be used. This process is otherwise similar to standard SVE and includes a system for handling off-gases.	This technology is typically applicable to VOCs and not PCBs since PCBs are not volatile.	Will require installation of extraction wells and vapor collection piping network.	No performance data are available for PCBs.	Requires significant heating of soils.	Moderate to High Cost	Not effective for PCBs. Eliminated.		✓
		In situ thermal desorption (ISTD)	ISTD is a thermal remediation technique by which thermal conductive heating (to 350 °C) is used to heat the predetermined treatment zone while slight vacuum is applied to the subsurface to extract soil vapors.	This technology is typically applicable to COC that are not very volatile at ambient temperatures, such as PCBs.	Will require installation of heating and extraction wells and vapor collection piping network.	Performance data are available for PCBs.	Requires significant heating of soils.	High Cost	Retained.	✓	

Table 5-5

Results of Preliminary Technology Screening
Block E Soil Remedial Action Plan
Middle River Complex, Middle River, Maryland

General Response Action	Remedial Action Technology	Process Option	Description	Quantitative Screening Based on Criteria Below					Results		
				Effectiveness (Primary)			Implementability	Relative Cost			
				Effectiveness in Handling Volumes of Impacted Media	Impacts during Implementation	Reliability			Screening Comment	Retain	Eliminate
In Situ Treatment (continued)	Physical/ Chemical (continued)	*In situ* stabilization	Mixing of chemical agents to bind, solidify, and reduce contaminant mobility. Binding agents are applied using a large diameter auger. Contaminants are physically bound or enclosed within a stabilized mass (solidification), or chemical reactions are induced between the stabilizing agent and contaminants to reduce their mobility (stabilization).	Well understood technology, can be utilized in areas with PCBs and PAHs.	Multiple overlapping borings are required. Volume increase after treatment may require off-site disposal of excess.	Long-term effectiveness is uncertain due to possible incompatibility between stabilizing agents.	Easily implementable with traditional construction techniques. Bench tests are required to determine stabilizing agents and effectiveness on site soils.	Moderate to High Cost	Retained. Would also prevent erosion of soil to sediment. Further evaluation will consider results of bench tests performed in 2017-2018.	✓	
	Biological	Enhanced bioremediation (aerobic)	Enhanced bioremediation is a process in which indigenous or inoculated microorganisms degrade organic contaminants in soils, converting them to innocuous end products. It typically involves the percolation of groundwater or potable water mixed with nutrients and saturated with dissolved oxygen. Acclimated organisms or other inoculum are also added. An infiltration gallery or spray irrigation is typically used for shallow contaminated soils, while injection wells are used for deeper contaminated soils.	The effectiveness of bioremediation is limited at sites with high concentrations of COC that are toxic to microorganisms and the presence of non-aqueous phase liquid (NAPL).	Bioremediation will take a long time to implement.	Bioremediation has not been documented to be very effective for removal of PCB or PAHs with more than two rings.	Requires a bench-scale and/or a pilot-scale test to determine oxygen and nutrient requirements.	Low to Moderate Cost.	Eliminated. For highly chlorinated compounds such as PCBs, aerobic bioremediation alone may not be effective unless an anaerobic step precedes.		✓
		Enhanced bioremediation (anaerobic)	In the absence of oxygen, microorganisms can metabolize organic contaminants to methane and carbon dioxide. With similar techniques employed in aerobic bioremediation, nutrients, microorganisms, and electron donors often are provided to promote anaerobic degradation of chlorinated compounds (reductive dechlorination) in the subsurface.	While anaerobic biodegradation of PCBs has been demonstrated, evidence to date does not support degradation of all congeners.	Bioremediation will take a long time to implement.	This technology is not reliable for reaching PRGs for PCB and PAHs.	Requires a bench-scale and/or a pilot-scale test to determine electron donor and nutrient requirements.	Low to Moderate Cost.	Eliminated.		✓
		Bioventing	Oxygen is delivered to contaminated unsaturated soils by forced aeration (either extraction or injection of air) to increase oxygen concentrations and stimulate biodegradation. In contrast to soil vapor extraction, bioventing uses low air flow to provide only enough oxygen to sustain microbial activity.	The presence of clayey soils, reduces bioventing performance significantly.	Bioremediation will take a long time to implement. Wells and piping network will affect site use.	Bioremediation has not been documented to be very effective for removal of PCB or PAHs with more than two rings.	Easily implementable with standard construction techniques, but low permeability soils would require a high density of wells.	Low to Moderate Cost.	Eliminated. PCBs are very recalcitrant and their degradation would be very slow		✓
		Phytoremediation	Use of selected plants cultivated in contaminated soil for uptake of metallic contaminants or enhancement of biodegradation of organic contaminants by indigenous microorganisms in the root zone.	Is effective only on soils that are in the root zone of plants that are used for phytoremediation.	Phytoremediation will take a long time to implement. Plant coverage will prevent site use.	May not be effective for PAHs or PCBs. Will require plant screening studies to assess effectiveness.	Significant implementability challenges.	Low to Moderate Cost.	Eliminated. This technology has limited demonstrated effectiveness for areas with high levels of PCBs.		✓

Table 5-5

Results of Preliminary Technology Screening
Block E Soil Remedial Action Plan
Middle River Complex, Middle River, Maryland

General Response Action	Remedial Action Technology	Process Option	Description	Quantitative Screening Based on Criteria Below					Results		
				Effectiveness (Primary)			Implementability	Relative Cost			
				Effectiveness in Handling Volumes of Impacted Media	Impacts during Implementation	Reliability			Screening Comment	Retain	Eliminate
Removal	Excavation	Conventional equipment excavation	Contaminated soil would be excavated using conventional equipment, such as backhoes, bulldozers, and clam shells. Dewatering would be needed prior to excavation of soil in saturated zone. In order to minimize excess excavation due to sloping on the sides of deep excavations, sheet piles may be installed.	Very effective in eliminating future risk and eliminating future exposure pathways, provided all areas with impacted soils have been identified.	Large quantities of soil have to be managed.	Reliable. Conventional equipment is used.	Easily implementable with traditional technology.	Moderate to High cost.	Retained for use with other technologies. Would also prevent erosion of soil to sediment.	✓	
	Excavation	Large diameter auger excavation	Contaminated soil would be excavated using large diameter (6 to 8 feet) augers. The boring would be backfilled with a flowable low-strength concrete to prevent collapse of the hole. Dewatering would be needed prior to excavation of soil in saturated zone.	Very effective in eliminating future risk and eliminating future exposure pathways, provided all areas with impacted soils have been identified.	Large quantities of soil have to be managed. Low strength concrete backfill may affect site re-use.	Uses specialized equipment used in construction.	Readily implementable but only by a limited number of contractors.	High cost.	Retained for use with other technologies.	✓	
Ex situ Treatment	Physical/ Chemical	Solidification/ stabilization	Mixing of chemical agents to bind, solidify, and reduce contaminant mobility. Contaminants are physically bound or enclosed within a stabilized mass (solidification), or chemical reactions are induced between the stabilizing agent and contaminants to reduce their mobility (stabilization).	Well understood technology, can be utilized in areas with PAHs and PCBs.	Large quantities of soils have to be processed. Because of volume increase after treatment some off-site disposal would be needed.	Long-term effectiveness is uncertain due to possible incompatibility between stabilizing agents.	Easily implementable with traditional construction techniques. Bench tests are required to determine stabilizing agents and effectiveness on site soils.	Moderate to High Cost	Retained. Would also prevent erosion of soil to sediment. Further evaluation will consider results of bench tests performed in 2017-2018.	✓	
		Chemical extraction	Chemical extraction does not destroy contaminants, but separate them from soils; therefore, reducing volume of hazardous waste that needs to be treated or disposed of. In general, contaminated soil and extractant are mixed in an extractor, dissolving the contaminants. The extracted solution is then placed in a separator, where the contaminants and extractant are separated for treatment and further use.	Potentially applicable to all COC at the site, but less effective on high molecular weight PAHs and PCBs and clayey soils. Chemical extraction alone cannot meet the clean-up goals. High level of fines difficult to treat.	Involves the excavation and handling of large volumes of soil and the treatment of large volumes of extraction solutions.	Reliability depends upon soil conditions/density	Readily implementable; but subsequent treatment processes are required to treat the extracted solution. Limited number of contractors.	High Cost	Eliminated. High capital cost may be required.		✓

Table 5-5

Results of Preliminary Technology Screening
Block E Soil Remedial Action Plan
Middle River Complex, Middle River, Maryland

General Response Action	Remedial Action Technology	Process Option	Description	Quantitative Screening Based on Criteria Below					Results		
				Effectiveness (Primary)			Implementability	Relative Cost			
				Effectiveness in Handling Volumes of Impacted Media	Impacts during Implementation	Reliability			Screening Comment	Retain	Eliminate
Ex situ Treatment (continued)	Physical/ Chemical (continued)	Soil washing	Unlike chemical extraction, soil washing is a water-based process. Contaminants sorbed onto fine soil particles are separated from bulk soil in an aqueous-based system. The wash water may be augmented with a basic leaching agent, surfactant, pH adjustment, or chelating agent to help remove organics and heavy metals.	Complex mixture of contaminants and heterogeneous soil matrix make it difficult to formulate a single solution that reliably removes all the COC. Sequential washing using different washing formulations may be required. High quantity of fines and clay will be difficult to treat.	Involves the excavation and handling of large volumes of soil, and the treatment of large volumes of washing solutions.	High concentrations of metals in site soils may interfere with extraction processes.	Readily implementable; but, subsequent treatment processes are required to treat the extracted solution. Limited number of experienced contractors.	Moderate to High Cost	Eliminated. Would require subsequent processing of large quantities of soils and washing solution.		✓
		Incineration	Only off-site incineration will be considered. High temperatures, 871-1,204 °C (1,600- 2,200 °F), are used to combust organic constituents in wastes in the presence of oxygen. There is no requirement for incineration of non-liquids regardless of concentration. Can be considered for hot spots to reduce future liability.	Effective, although fines and clay are more difficult to process.	Involves the excavation and off-site transport of large volumes of soil.	Reliable	Readily implementable, although there are few TSCA incineration facilities.	Moderate to High Cost	Retained. Can be used as alternative to landfilling for disposal.	✓	
		Thermal desorption	Wastes are heated to volatilize organic contaminants. A carrier gas or vacuum system transports volatilized organics to the gas treatment system. High temperatures will be required to remove PCBs from soils. The off-gas may require further treatment.	Effective, although fines and clay are more difficult to process.	Will require off-gas treatment.	May not be effective for all PAHs.	Requires large amounts of energy. Limited number of experienced contractors.	Moderate to High Cost	Retained for soils impacted with PCBs.	✓	
	Biological	Biopiles	Excavated soils are mixed with soil amendments and placed on a lined treatment area that includes leachate collection and aeration. This technology is used to treat organic contaminants in excavated soils through biodegradation. Moisture, heat, nutrient, oxygen, and pH need to be controlled. The designated treatment area will be covered or contained with an impermeable liner to minimize runoff and leaching contaminants into groundwater or other uncontaminated areas. Soil piles can be up to 20 feet high with an air distribution system buried under the soil piles.	Biopile technology has been used for treatment of halogenated and non-halogenated VOCs, SVOCs, and pesticides. Clayey soils would be difficult to manage and treat. However, its performance varies significantly at sites.	Substantial space would be required. Excavations would have to remain open until backfilled with treated soils. Bioremediation will take a long time to implement.	Reliability must be assessed through bench-scale testing. It is uncertain whether this technology is effective in treating PCBs and 1,2,4-TCB.	Easily implementable with standard construction techniques. However, a bench-scale and a pilot-scale test should be conducted to determine the biodegradability of COC at the site.	Moderate Cost	Eliminated. Effectiveness not demonstrated.		✓

Table 5-5

Results of Preliminary Technology Screening
Block E Soil Remedial Action Plan
Middle River Complex, Middle River, Maryland

General Response Action	Remedial Action Technology	Process Option	Description	Quantitative Screening Based on Criteria Below					Results		
				Effectiveness (Primary)			Implementability	Relative Cost			
				Effectiveness in Handling Volumes of Impacted Media	Impacts during Implementation	Reliability			Screening Comment	Retain	Eliminate
Ex situ Treatment (continued)	Biological (continued)	Landfarming	Landfarming is a full-scale bioremediation technology similar to composting. Land Farming differs from composting because it incorporates contaminated soil into soil that is uncontaminated. Composting also generally takes place in aboveground piles. Contaminated soils are mixed with soil amendments such as soil bulking agents and nutrients, and then they are tilled into the earth. Liners are usually incorporated to control leaching of contaminants. Contaminated soils are periodically tilled for aeration. Contaminated soil is usually treated in lifts that are up to 18 inches thick. When the desired level of treatment is achieved, the lift is removed and a new lift is constructed.	This technology is only effective in the top 2 to 3 feet. In general, landfarming is not effective in treating high molecular weight PAHs and chlorinated compounds.	Requires substantial space. Must be properly managed to prevent off-site migration of contaminants. Bioremediation will take a long time to implement.	It is uncertain whether this technology is effective in treating PCBs and 1,2,4-TCB.	Easily implementable with standard construction techniques. However, a bench-scale and a pilot-scale test should be conducted to determine the biodegradability of COC at the site.	Moderate Cost	Eliminated. Effectiveness not demonstrated.		✓
		Composting	Composting is a biological process to convert organic contaminants to innocuous end products. Typically, thermophilic conditions (i.e., 54 to 65 °C) must be maintained. Soils are excavated and mixed with bulking agents such as wood chips and mixed to promote biodegradation.	Composting results in a volumetric increase because of the addition of amendment materials. Composting has been demonstrated to degrade many organic contaminants in soils, including PAHs, there few applications of the technology at any scale to PCBs. All materials and equipment used for composting are readily available.	Similar to biopiles, composting requires substantial space. Bioremediation will take a long time to implement. Excavations would have to remain open until backfilled with treated soils.	Reliability has to be assessed through bench-scale testing. PAHs and PCBs are relatively slow to biodegrade.	Easily implemented with standard construction techniques.	Moderate Cost	Eliminated. Uncertainty of effectiveness for PCBs, long time for treatment, and long-term open excavations.		✓
		Slurry phase biological treatment	An aqueous slurry is created by combining soil (after removing stones and debris) and sludge (from wastewater treatment plants) with other additives in a tank or vessel. Typically, a slurry contains 10 to 30% solids by weight. Proper oxygen level and pH need to be monitored. The slurry is mixed to keep solids suspended and microorganisms in contact with the soil contaminants. Upon completion of the process, the slurry is dewatered and the treated soil is disposed of.	Slurry-phase biological treatment has been used to treat non-halogenated (e.g., PAHs) and halogenated compounds such as PCBs and other VOCs and SVOCs. Clayey soils may be difficult to manage.	Soil would have to be excavated and processed through reactors. Dewatering soil fines after treatment can be expensive. Wastewater disposal options need to be identified.	Reliability has to be assessed through bench-scale testing.	Sizing of materials prior to putting them into the reactor is challenging and expensive, especially for nonhomogeneous soils and clayey soils present at the site.	High Cost	Eliminated. Very difficult to implement.		✓

Table 5-5

Results of Preliminary Technology Screening

Disposal	Off-Site	Landfill	Excavated soil would be transported off-site to a landfill. Soil with PCB concentrations greater than 50 ppm must go to a TSCA-approved landfill or RCRA hazardous waste landfill.	Landfilling is an effective method of disposal. Exposure pathway would be eliminated.	Large quantities of soil have to be transported.	Off-site landfilling is reliable.	Easily implementable.	Moderate Cost.	Retained. Effective and easy to implement. Soil subject to erosion and transport to sediment would be removed.	✓	

Abbreviations:

COC – chemicals of concern
COMAR – Code of Maryland Regulations
DCB – dichlorobenzene
Fe^{0-} zero-valent iron
ISTD – *in situ* thermal desorption
ISV – *in situ* vitrification
MDE – Maryland Department of the Environment
MRC – Middle River Complex
NAPL – non-aqueous phase liquid
ORP – oxidation-reduction potential
PAHs – polycyclic aromatic hydrocarbons
PCBs – polychlorinated biphenyls
PRB – permeable reactive barrier
RAO – remedial action objective
RCRA – Resource Conservation and Recovery Act
RRA – residual risk analysis
SVE – soil vapor extraction
SVOCs – semivolatile organic compounds
TCB – trichlorobenzene
TCE – trichloroethene
TSCA – Toxic Substances Control Act
VOCs – volatile organic compounds
ZVI – zero valent iron

Technologies and Process Options
Block E Soil Remedial Action Plan
Lockheed Martin Middle River Complex, Middle River, Maryland

General Response Action	Remedial Action Technology	Process Option	Description
No Action	None	Not Applicable	No activities conducted in the block to address contamination.
Limited Action	land use controls	Site use restrictions	Administrative action using excavation permits and other land use prohibitions to restrict future site activities.
Containment	capping	Soil cover/cap that meets TSCA requirements	Various types of capping systems can minimize infiltration and prevent human exposure from direct contact. Also reduces runoff of impacted soils and sediments with stormwater.
In situ treatment	physical/chemical	*In situ* thermal desorption (ISTD)	ISTD is a thermal remediation technique by which thermal conductive heating (to 350 °C) is used to heat the predetermined treatment zone while slight vacuum is applied to the subsurface to extract soil vapors.
In situ treatment	physical/chemical	*In situ* stabilization	Mixing of chemical agents to bind, solidify, and reduce contaminant mobility. Binding agents are applied using a large diameter auger. Contaminants are physically bound or enclosed within a stabilized mass (solidification), or chemical reactions are induced between the stabilizing agent and contaminants to reduce their mobility (stabilization).
Removal	excavation	Conventional equipment	Contaminated soil would be excavated using conventional equipment, such as backhoes, bulldozers, and clam shells.
Removal	excavation	Large diameter auger	Contaminated soil would be excavated using large diameter (5 to 8 feet) augers. The boring would be backfilled with a flowable low-strength concrete to prevent collapse of the hole.
Ex situ treatment	physical/chemical	Incineration	High temperatures, 871-1,204 °C (1,600- 2,200 °F), are used to combust organic constituents in wastes in the presence of oxygen. Only off-site incineration will be considered.

Remedial Action Objectives / Risk Pathways		**No Action**	**Placement of a TSCA-compliant cap over Impacted soil and institutional controls**	**Excavation and off-site disposal of impacted surface and subsurface soil using conventional methods**	**Excavation of impacted surface soil using conventional methods and subsurface soil using large diameter augers and off-site disposal**	**Excavation of impacted surface soil using conventional methods with off-site disposal and *in situ* stabilization of subsurface soil using large diameter augers**
Remedial Action Objective	**Risk Pathway**					
Reduce site-related chemicals of concern (COC) in Block E soils to not exceed a cumulative 1×10 5 human health cancer-risk level and to less than a cumulative non-carcinogenic hazard index of one for industrial workers and construction workers.	Ingestion, inhalation, and dermal contact	Not Applicable	Risk pathway mitigated via placement of a cover Institutional controls will mitigate risk associated with residual contamination in deeper soils	Risk pathway mitigated via excavation and disposal of surface and subsurface soils. Institutional controls will mitigate risk associated with residual contamination in remaining soils.	Risk pathway mitigated via excavation and disposal of surface and subsurface soils. Institutional controls will mitigate risk associated with residual contamination in remaining soils.	Risk pathway mitigated via excavation and disposal of surface soils. Risk pathway mitigated via stabilization of subsurface soils. Institutional controls will mitigate risk associated with residual contamination in remaining soils.
Prevent transfer of polychlorinated biphenyls to the extent practicable from surface soil and storm drains to discharged stormwater at concentrations that would impact the sediment remedy.	Erosion and transport of impacted soils	Not Applicable	Pathway mitigated by placement of soil cover.	Pathway mitigated by removal of most impacted surface soils and use of clean soil for the bottoms of stormwater channels.	Pathway mitigated by removal of most impacted surface soils and use of clean soil for the bottoms of stormwater channels.	Pathway mitigated by removal of most impacted surface soils and use of clean soil for the bottoms of stormwater channels.
Prevent to the extent practicable leaching of PCBs and 1,2,4-trichlorobenzene from soil to groundwater at concentrations that would impact surface water concentrations.	Migration from impacted soils to ground-water	Not Applicable	Migration from impacted soil in the saturated zone would continue.	Pathway mitigated by removal of most impacted surface and subsurface soils.	Pathway mitigated by removal of most impacted surface and subsurface soils.	Pathway mitigated by removal of most impacted surface soils and stabilization of subsurface soils.

COC - chemical(s) of concern
PCBs - polychlorinated biphenyls
TSCA - Toxic Substances Control Act

Development of Remedial Alternatives
Block E Soil Remedial Action Plan
Middle River Complex, Middle River, Maryland

6	7	8
Excavation of impacted surface and subsurface soil using conventional methods, on-site *ex situ* stabilization, and on-site reuse of treated soil	**Excavation of impacted surface soil using conventional methods with off-site disposal and *in situ* thermal desorption of subsurface soil**	**Excavation of impacted surface and subsurface soil using conventional methods, on-site *ex situ* thermal desorption, and on-site reuse of treated soil**
Risk pathway mitigated via excavation and disposal of surface soils. Risk pathway mitigated via stabilization of subsurface soils. Institutional controls will mitigate risk associated with residual contamination in remaining soils.	Risk pathway mitigated via excavation and disposal of surface soils. Risk pathway mitigated via thermal treatment of subsurface soils. Institutional controls will mitigate risk associated with residual contamination in remaining soils.	Risk pathway mitigated via excavation and treatment of surface and subsurface soils. Institutional controls will mitigate risk associated with residual contamination in remaining soils.
Pathway mitigated by treatment of most impacted surface soils and use of clean soil for the bottoms of stormwater channels.	Pathway mitigated by removal of most impacted surface soils and use of clean soil for the bottoms of stormwater channels.	Pathway mitigated by treatment of most impacted surface soils and use of clean soil for the bottoms of stormwater channels.
Pathway mitigated by stabilization of most impacted surface and subsurface soils.	Pathway mitigated by removal of most impacted surface and treatment of subsurface soils.	Pathway mitigated by treatment of most impacted surface and subsurface soils.

Table 5-8

Retained and Eliminated Alternatives Based on Preliminary Screening
Block E Soil Remedial Action Plan
Lockheed Martin Middle River Complex, Middle River, Maryland

Alternative	Retained?
Alternative 3: Excavation and disposal of impacted surface and subsurface soil using conventional methods	yes
Alternative 4: Excavation of impacted surface soil using conventional methods and subsurface soil using large diameter augers and off-site disposal	yes
Alternative 7: Excavation of impacted surface soil using conventional methods with off-site disposal and *in situ* thermal desorption of subsurface soil	yes
Alternative 8: Excavation of impacted surface and subsurface soil using conventional methods and on-site *ex situ* thermal desorption	yes
Alternative 5: Excavation of impacted surface soil using conventional methods with off-site disposal and *in situ* stabilization of subsurface soil using large diameter augers	no
Alternative 6: Excavation of impacted surface and subsurface soil using conventional methods and on-site *ex situ* stabilization	no
Alternative 2: Placement of a TSCA-compliant cap over impacted soil and institutional controls.	no
Alternative 1: No action	retained for comparison

TSCA - Toxic Substances Control Act

Table 5-9

Comparative Analysis of Alternatives
Block E Soil Remedial Action Plan
Lockheed Martin Middle River Complex, Middle River, Maryland

Evaluation Criteria	Evaluation Sub-Criteria	Alternative 1	Alternative 3	Alternative 4	Alternative 7	Alternative 8
Long Term Effectiveness & Permanence	Residual Potential Long Term Effectiveness and Risk (Assuming Remedy Failure)	Does not alter risk	Very effective in eliminating risk.	Very effective in eliminating risk. Existing piles will prevent complete subsurface soil removal at Transformer Room No. 2.	Very effective in eliminating risk.	Very effective in eliminating risk.
	Technology Reliability	Very unreliable	Reliable technology	Reliable technology	Reliable technology. Uncertain effectiveness of ISTD because there are few applications of the technology on PCBs	Reliable technology
Reduction of TMV through Treatment	Destruction of Hazardous Constituents	No destruction	No destruction, only removal and relocation to off-site landfill.	No destruction, only removal and relocation to off-site landfill.	Can achieve complete destruction in the areas where it is applied	Can achieve complete destruction in the excavated soil
	Irreversibility of Treatment	No treatment	Impacted surface and subsurface soils are removed.	Impacted surface and subsurface soils are removed.	Treatment is completely irreversible since COC are thermally treated or removed.	Treatment is completely irreversible since COC are thermally treated.
Short Term Effectiveness	Time to Achieve RAOs	Very long timeframe	Will require a long duration since large volumes of soil are to be removed. (7 months)	Will require a long duration since large volumes of soil are to be removed. (8 months)	Will require a long duration since large volumes of soil are to be removed and/or treated. (14 months)	Will require a long duration since large volumes of soil are to be removed and treated. (9 months)
	Un-mitigable Adverse Impacts During Construction and OM&M	None	Will require dust control, air monitoring, sidewall protection, and treatment of groundwater.	Will require dust control, air monitoring, and treatment of groundwater.	Will require dust control, air monitoring, and emission controls for ISTD.	Will require dust control, air monitoring, sidewall protection, treatment of groundwater, and emission controls for thermal process.
Implementability	Obtaining Other Approvals	Because no actions are proposed, no other approvals are necessary	Will require: critical area permits SEC permits air monitoring during RA implementation NPDES permit T&D facility requirements	Will require: critical area permits SEC permits air monitoring during RA implementation NPDES permit T&D facility requirements	Will require: critical area permits SEC permits air monitoring during RA implementation NPDES permit Air permit T&D facility requirements	Will require: critical area permits SEC permits air monitoring during RA implementation NPDES permit TSCA permit (by thermal sub) T&D facility requirements

Table 5-9

Comparative Analysis of Alternatives
Block E Soil Remedial Action Plan
Lockheed Martin Middle River Complex, Middle River, Maryland

Evaluation Criteria	Evaluation Sub-Criteria	Alternative 1	Alternative 3	Alternative 4	Alternative 7	Alternative 8
Implementability (continued)	Constructability	Easily constructible	Requires dewatering and T&D of large volumes of soil. Can be implemented using standard construction techniques.	Requires dewatering treatment, and T&D of large volumes of soil. Surface soil excavation implemented using standard construction techniques, but subsurface uses specialized equipment. Existing piles will interfere with augers.	Requires shoring, dewatering, installation of heating and vapor extraction wells, and specialized equipment to heat the soil.	Requires dewatering and management of large volumes of soil. Requires specialized equipment to thermally treat the soil. Soils with high clay content are difficult to treat.
	Availability of Experts and Technology	Does not require any expertise	Expertise and technology is readily available.	Very few companies have expertise and technology for auger excavation.	Very few companies have expertise and technology for ISTD.	Very few companies have expertise and technology for on-site ex situ thermal treatment. Limited number of treatment systems are available.
	Adaptability to Modify/Update as Necessary	Alternative can be modified as required.	Alternative can be modified as required.	Alternative can be modified as required.	ISTD can be somewhat difficult to modify after installation.	Alternative can be modified by extending the operation as required to treat additional soil.
	Effectiveness of Monitoring	No monitoring, very ineffective.	Removal of impacted soils can be ascertained by sampling.	Removal of impacted soils can be ascertained using DPT along sides, but bottom cannot be sampled.	Removal of impacted surface soils can be ascertained by sampling. Treatment of subsurface soil can only be evaluated by DPT sampling after treatment.	Removal of impacted soils can be ascertained by sampling. Effectiveness of thermal process can be evaluated by sampling and analysis.
Environmental	Energy Use	No energy usage	Less energy usage than Alternatives 7 and 8	Less energy usage than Alternatives 7 and 8	Second highest energy usage.	Highest energy usage.
	Air Emissions	No emissions	Emissions during excavation and transportation of impacted soils to disposal facilities and transportation of clean fill to the site.	Emissions during excavation and transportation of impacted soils to disposal facilities and transportation of clean fill to the site.	Off-gas from ISTD would be treated. Emissions during excavation and transportation of impacted soils to disposal facilities and transportation of clean fill to the site.	Air emissions for production of energy to treat soils. Off-gas from thermal process would be treated. Emissions during excavation and management of impacted and treated soils.
	Impacts on Water Resources	No impacts	Requires water for dust control	Requires water for dust control	Requires water for dust control and off-gas cooling.	Requires water for dust control and off-gas cooling.
Costs	Total Cost	$0	$21,920,000	$23,280,000	$31,720,000	$24,690,000

COC - chemical(s) of concern
DPT - direct-push technology
ISTD - in situ thermal desorption
O&M - operation and maintenance
OM&M - operation, maintenance, and monitoring
RA - remedial action
RAOs - remedial action objectives
SEC - significant environmental concern
T&D - treatment and disposal
TMV - toxicity, mobility, and volume

Alternative 1: No Action
Alternative 3: Excavation and disposal of impacted surface and subsurface soil using conventional methods
Alternative 4: Excavation of impacted surface soil using conventional methods and subsurface soil using large-diameter augers and off-site disposal
Alternative 7: Excavation of impacted surface soil using conventional methods with off-site disposal and *in situ* thermal desorption of subsurface soil
Alternative 8: Excavation of impacted surface and subsurface soil using conventional methods and on-site *ex situ* thermal desorption

Table 6-1

Potential Contingencies, Based on the Results of Post-Remedial Action Sampling
Page 1 of 2

Remedial action objective	Metrics	Contingencies
1.) Reduce site-related chemicals of concern (COC) in Block E soil to not exceed a cumulative 1×10^{-5} human health cancer-risk level and to less than a cumulative non-carcinogenic hazard index of one for industrial- and construction-workers.	1.) Removal of polychlorinated biphenyl (PCB)-impacted surface and subsurface soil, based on residual risk analysis (RRA) (includes confirmatory samples)	1). Additional excavation until RRA is met
2.) Prevent transfer of polychlorinated biphenyls to the extent practicable from surface soil and storm drains to stormwater at concentrations that would impact the sediment remedy.	1.) Removal of PCB-impacted surface soil, based on RRA 2.) Cleaning or replacement of contaminated storm-drains 3.) Restoring excavated areas with clean backfill 4.) Establishing engineering controls, including vegetation or other cover	1.) Additional excavation until RRA met 2.) If vegetative or other covers are removed, prevent stormwater runoff until new engineering control is installed.

Table 6-1

Potential Contingencies, Based on the Results of Post-Remedial Action Sampling
Page 2 of 2

Remedial action objective	Metrics	Contingencies
3.) Prevent to the extent practicable leaching of polychlorinated biphenyls and 1,2,4-trichlorobenzene (TCB) from soil to groundwater at concentrations that would impact surface water concentrations.	1.) Removal of PCB-impacted surface and subsurface soil, based on RRA 2.) Groundwater monitoring to establish that groundwater concentrations of PCBs and 1,2,4-TCB are stable or decreasing	1.) Additional excavation until RRA met 2.) If, after 2 years of monitoring, PCB and/or 1,2,4-TCB concentrations in groundwater indicate increasing groundwater concentrations, then continue monitoring for up to 5 years. If sentinel wells continue to show statistically significant increased contamination, then consider additional remedial measures.

Table 7-1

Atomic Energy Commission Regulatory Guide: Acceptable Surface-Contamination Levels Block E Soil Remedial Action Plan Middle River Complex, Middle River, Maryland

Radionuclides	Chemical Abstract Service number	Surfaces (dpm/100 cm^2)[(1)]	Soil (pCi/g)		
		Structures, materials and equipment, waste	Goal[(2)]	Laboratory quantitation limit	Laboratory minimum-detectable concentration
Uranium-235	12117-96-1	5,000	4.8	0.5	0.5

Notes:

[(1)] Based on *AEC Regulatory Guide 1.86* (AEC 1974). Values indicate the measured value above background, as determined from the reference area. Limits for removable surface activity are 20% of these values.

[(2)] Based on Nuclear Regulatory Commission document NUREG-1757, *Consolidated Decommissioning Guidance* (NRC 2006), whose limits are deemed in compliance with the 25 mrem/y unrestricted-dose limit in 10 CFR 20.1402. Listed values were developed by scaling the NUREG-1757 values to 15 mrem/y unrestricted dose. Criteria are above background for those radionuclides found in background soil.

cm^2 = square centimeters

dpm = disintegration(s) per minute

mrem/y = millirem(s) per year

pCi/g = picocurie(s) per gram

Table 7-2

Backfill Material Acceptance Criteria
Block E, Soil Remedial Action Plan
Lockheed Martin Middle River Complex, Middle River, Maryland

Parameter	Criteria	Test method
Volatile organic compounds	MDE residential cleanup standards or ATCs[(1)] or associated approved risk-based concentrations	USEPA SW-846 8260B
Semivolatile organic compounds	MDE residential cleanup standards or ATCs[(1)] or associated approved risk-based concentrations	USEPA SW-846 8270C[(2)]
Polychlorinated biphenyls	MDE residential cleanup standards or ATCs[(1)] or associated approved risk-based concentrations	USEPA SW-846 8082
Metals	MDE residential cleanup standards or ATCs[(1)] or associated approved risk-based concentrations	USEPA SW-846 6020
Pesticides (organochlorine)	MDE residential cleanup standards or ATCs[(1)] or associated approved risk-based concentrations	USEPA SW-846 8081A or 8080A
Pesticides (organophosphorus)	MDE residential cleanup standards or ATCs[(1)] or associated approved risk-based concentrations	USEPA SW-846 8141A
Chlorinated herbicides	MDE residential cleanup standards or ATCs[(1)] or associated approved risk-based concentrations	USEPA SW-846 8151A
Total petroleum hydrocarbons	MDE residential cleanup standards or ATCs[(1)] or associated approved risk-based concentrations	USEPA SW-846 8015B

The off-site borrow source must be approved by the MDE Voluntary Cleanup Program before transporting any backfill material onto the site.

[(1)]Residential cleanup standards and ATCs provided in *Cleanup Standards for Soil and Groundwater* (MDE, 2008).
[(2)]Carcinogenic polycyclic aromatic hydrocarbons using USEPA SW-846 8270C or D with SIM.

ASTM = ASTM International, Inc.
ATC = anticipated typical concentration
MDE = Maryland Department of the Environment
SIM = selected-ion monitoring
USCS = Unified Soil Classification System

Subject: Withdrawal of VCP Applications for Tax Parcel Blocks D, E, E (Lot 3), F, G (Lot 1), H and I
Chesapeake Park Plaza (Middle River Complex)
2323 Eastern Boulevard, Middle River, Baltimore County, Maryland

Dear Mr. Carroll:

The purpose of this letter is to notify the Maryland Department of the Environment ("MDE" or "Department") that Lockheed Martin Corporation is withdrawing the below referenced tax parcels and block numbers, generally referred to as the Chesapeake Park Plaza, from the Voluntary Cleanup Program ("VCP") pursuant to Md. Code Ann. Envir. § 7-512 (2007 Repl. Vol.).

The subject Chesapeake Park Plaza tax parcels were previously accepted into MDE's VCP. This notice of withdrawal will affect the following identified tax parcels:

	Tax Parcel Number	**Acreage**
1	Map 90 Grid 18 Parcel 964 Block D	12.775
2	Map 90 Grid 18 Parcel 964 Block E	15.433
	Map 90 Grid 18 Parcel 964 Block E Lot 3	0.533
3	Map 90 Grid 18 Parcel 964 Block F	11.941
4	Map 90 Grid 18 Parcel 964 Block G Lot 1	13.461
5	Map 90 Grid 18 Parcel 964 Block H	7.877
6	Map 90 Grid 18 Parcel 964 Block I	66.104

We understand this notice will take effect upon ten (10) days of MDE's receipt. Please be advised that the tax parcels subject to this notice are currently stable and secure, and that Lockheed Martin has agreed in principle to negotiate an administrative consent order with the Department to address environmental conditions at Tax Parcels D, E, F, G, and H, and I. Please acknowledge receipt of this notice in writing.

Please let me know if you have any questions. My office phone is (301) 548-2212.

Sincerely,

Carol B. Cala
Vice President, Energy, Environment, Safety & Health
Lockheed Martin Corporation

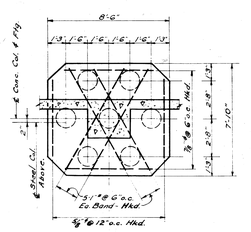
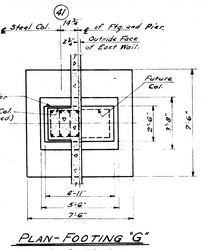
See Detail



Note:- Concrete in columns up to slab to be 3000 #/in. in 28 days. See Arch. Drwgs. for metal guards required on concrete columns.

Typically the elevations of bottom of footings are given in schedule. Only such footings which are required to be at other than typical elevation in order to clear heating installations, conductors, etc. are noted on the plan below.



* FOR DETAIL, SEE SHEET S-5.

Scale ½"=1'-0"

FOOTING PLAN
Scale 1/32"=1'-0"

Note:- Where, for any reason, footings are lowered so that top of cap is more than 8" below basement floor, properly reinforced piers will be required as indicated in the column and footing schedule. In case piers are less than 2'-0" high, the vertical pier steel should extend 30 diameters into column above; and also into footing below.

VC	vinyl chloride

SECTION 1
INTRODUCTION

The *Human Health Risk Assessment (HHRA) for Blocks D, E, F, G, and H Soils, Lockheed Martin Middle River Complex, 2323 Eastern Boulevard, Middle River, Maryland* (Tetra Tech, 2012) identified chemicals of concern (COC) in soil that require remediation if the typical industrial worker and the construction worker are receptors of concern. This document was prepared to support the remedial action plan (RAP) for Block E soil, assuming current and future industrial land use. Specifically, the residual risk analysis contained herein assumes that a typical industrial worker may be exposed to chemicals of concern in surface soil, and a typical construction worker might potentially be exposed to chemicals of concern in surface and subsurface soil. Institutional controls preventing industrial worker exposure to subsurface soil are assumed to be in place. However, construction workers might be exposed during occasional excavation that supports construction, utility repairs, or expansion.

The residual risk analysis uses a risk assessment approach to select locations for remediation so that the following risk management goals established by the Maryland Department of the Environment (MDE) are achieved:

- Maryland Department of the Environment cumulative cancer and non-cancer risk benchmarks for receptors exposed to chemicals of concern in an exposure unit (i.e., an area in which receptor activities typically occur) are no greater than 1×10^{-5} (i.e., a one-in-100,000 excess probability of developing cancer) and a hazard index (HI) of 1, for cancer risk and noncancer effects, respectively. (Potential adverse noncarcinogenic health effects might occur if the calculated hazard index for a target organ exceeds 1.) Risk estimates greater than these benchmarks are considered unacceptable by the Maryland Department of the Environment.

- "Hot spot" areas in soil will also be addressed by the remedial action plan. The Maryland Department of the Environment defines a "hot spot" as a location with a cancer risk estimate exceeding 1×10^{-4} (i.e., a one-in-10,000 excess probability of developing cancer) or a hazard index greater than 100.

Stated alternatively, this analysis will identify locations that must be remediated to achieve risk management goals (Lockheed Martin, 2018), while ensuring that "representative" soil concentrations do not exceed the risk-based preliminary remediation goals (PRGs) established for Block E soil. For purposes of the human health risk assessment, a "representative" soil concentration (also referred to as the exposure point concentration [EPC]) is typically defined as the 95% upper confidence limit (UCL) on the arithmetic mean. A 95% upper confidence limit is a value that, when repeatedly calculated for randomly drawn subsets of size *n*, equals or exceeds the true population mean 95% of the time. The 95% upper confidence limit provides a measure of uncertainty in the mean.

SECTION 2
METHODOLOGY

The residual risk analysis (RRA) followed the six steps described below. Attachment A includes histograms displaying the distribution of key chemical concentrations in Block E soil; tables including the detailed results of the RRA are in Attachment B.

Step 1: Identification of chemicals of concern:
Several sampling events have been conducted at Block E since the 2012 human health risk assessment (HHRA) was prepared. Changes have also been made in the screening criteria used to identify the chemicals of potential concern (COPC) evaluated in the 2012 HHRA. As a first step in this RRA, concentrations of chemicals in surface soil and subsurface soil were compared to the November 2017 United States Environmental Protection Agency (USEPA) regional screening levels (RSL) to determine if any new significant COPC were present in Block E. Tables C.1.1 and C.1.2 in Attachment C present the screening comparison for surface soil and subsurface soil, respectively. Surface soil is defined as all samples collected from 0–2 feet below ground surface (bgs). Subsurface soil is defined as two feet bgs to the vertical limit of contamination. The preliminary remediation goal (PRG) of 58 milligrams per kilogram (mg/kg) for the polychlorinated biphenyl (PCB) Aroclor 1260 (developed using a construction worker exposure scenario) was used to determine the vertical limit of contamination, which is 20 feet bgs.

Chemicals of potential concern for surface soil (0–2 feet bgs)—The following chemicals were identified as COPC for the exposure to surface soil scenario (see Attachment C, Table C.1.1):

- 1,2,3-trichlorobenzene (1,2,3-TCB)
- 1,2,4-trichlorobenzene (1,2,4-TCB)
- 1,4-dichlorobenzene (1,4-DCB)
- ethylbenzene
- total xylenes
- trichloroethene (TCE)
- benzo(a)pyrene equivalent (BaPEq)
- naphthalene

- PCBs (Aroclor 1242)
- PCBs (Aroclor 1248)
- PCBs (Aroclor 1254)
- PCBs (Aroclor 1260)
- antimony
- arsenic
- cobalt
- hexavalent chromium
- iron
- lead
- manganese
- mercury
- thallium
- vanadium

Ethylbenzene, total xylenes, TCE, naphthalene, Aroclor 1248, and thallium were not identified as COPC for surface soil in the 2012 HHRA. Although lead was detected in 35 of 37 surface soil samples, its concentration exceeded (470 mg/kg) the residential RSL of 400 mg/kg in only one sample; however, this concentration was less than the industrial RSL of 800 mg/kg. Both the average lead concentration (46 mg/kg) and its UCL (101 mg/kg) are less than the residential and industrial RSLs, so lead is not evaluated further in this RRA.

Chemicals of potential concern for subsurface soil (2–20 feet bgs)—The following chemicals were identified as COPC for exposure to subsurface soil (Attachment C, Table C.1.2):

- 1,2,3-TCB
- 1,2,4-TCB
- 1,2-dichlorethane (1,2-DCA)
- 1,3-DCB
- 1,4-DCB
- TCE
- vinyl chloride (VC)
- BaPEq
- PCBs (Aroclor 1242)
- PCBs (Aroclor 1254)
- PCBs (Aroclor 1260)
- arsenic
- cobalt
- hexavalent chromium
- iron
- manganese
- thallium
- vanadium

Aroclor 1242 was not identified as a COPC for subsurface soil in the 2012 HHRA.

Chemicals of concern for surface soil (0–2 feet bgs)—Chemicals of concern (COC) are those chemicals considered primary contributors to excess health risks (i.e., individual chemicals contributing to an incremental lifetime cancer risk level greater than 1×10^{-6} [i.e., a one-in-a-million excess probability of developing cancer] or a hazard quotient greater than 1). The HHRA results indicate that polychlorinated biphenyls (PCBs [predominantly Aroclor mixture 1260]), carcinogenic polycyclic aromatic hydrocarbons (cPAHs) evaluated as BaPEq, and 1,2,4-TCB are the COC for the exposure to surface soil scenario in Block E (Tetra Tech, 2012). BaPEq were calculated per the methodology presented in the HHRA. This RRA evaluates BaPEq and PCB concentrations detected in surface soil, because these two COC are the primary risk drivers. 1,2,4-TCB was co-located with significant PCB concentrations. Locations targeted for remediation were identified on the basis of BaPEq and PCBs concentrations in soil samples, these soil samples were then excluded from the risk analysis data sets, and exposure point concentrations (EPCs) and risk estimates associated with the "remaining" soil were recalculated for each tax block (as detailed below) to demonstrate that risk management goals would be achieved.

Chemicals of concern for subsurface soil (2–20 feet bgs)—The HHRA results indicate that BaPEq, Aroclor 1254, Aroclor 1260, and 1,2,4-TCB are the COC for exposures to subsurface soil in Block E (Tetra Tech 2012). Although not identified as a COC in the 2012 HHRA, TCE is also considered a COC for subsurface soil for the RRA. TCE was detected at elevated concentrations in subsurface soil in the Southeast Subarea of Block E after an underground storage tank (UST) was found just outside the building foundation. The UST, which contained high concentrations of TCE, has been removed and groundwater remediation is ongoing in this area. The groundwater remedy will address TCE in soil in the Southeast Subarea of Block E.

Subsurface soil was evaluated as one exposure unit (EU) in the 2012 HHRA. Investigations since 2012 have identified several subareas of elevated COC concentrations. Three subareas are located where subsurface transformer rooms associated with former Building D were once located. A fourth subarea in the southeast area has a distinct chemical signature, with Aroclor 1254 and TCE as the predominant COC, in contrast to the soil beneath former Building D that has Aroclor 1260 as the predominant COC. These subareas were evaluated separately in this RRA to ensure that potential risks posed to construction workers are not underestimated, as construction or excavation scenarios are typically predicated on localized areas. To support this subarea risk approach for the

construction scenario, Attachment A includes histograms displaying the distribution of PCB concentrations in Block E soil before any samples were removed from the data sets. These histograms demonstrate that risk estimates are strongly influenced by elevated concentrations detected at relatively few sampling locations. Consequently, risk may be underestimated if subsurface soil at Block E is treated as one EU, because, although more than 1,400 subsurface soil samples have been collected across Block E, COPC concentrations detected in most samples do not exceed the calculated PRGs (i.e., low-level or non-detect results are reported for most subsurface soil samples in Block E). Thus, EPCs calculated based on COC concentrations for *all* Block E subsurface soil samples might not represent the contaminant levels detected in the subareas that have elevated PCB concentrations. Therefore, subsurface soil was divided into five EUs for evaluation in this RRA: (1) Transformer Room #2 Subarea, (2) Transformer Room #3 Subarea, (3) Transformer Room #4 Subarea, (4) Southeast Subarea, and (5) Block E-wide subsurface soil, excluding the other four subareas (Figure 2-1).

Step 2: Determination of PRGs:

Surface soil preliminary remediation goals—Risk-based PRGs for the industrial worker and construction worker exposure scenarios were calculated for all surface soil and subsurface soil COC; these goals are presented in the *Technical Memorandum—Mr. Tom D. Blackman to Ms. Ruth Prince and Mr. James R. Carroll, Preliminary Remediation Goals for Industrial and Construction Workers, Block E Soil Remediation, Lockheed Martin Middle River Complex, Middle River, Maryland* (Lockheed Martin, March 2018). The PRG for Aroclor 1260 (10 mg/kg) represents the 1×10^{-5} cancer risk level (i.e., a one-in-100,000 excess probability of developing cancer). The PRG for BaPEq (2.9 mg/kg) represents the 1×10^{-6} (i.e., a one-in-a-million excess probability of developing cancer) cancer risk level to meet the cumulative risk benchmark of 1×10^{-5} and to be consistent with the PRG for BaPEq used at Blocks D, F, G, and H. The PRG selected for PCBs is also the conservative (lower) end of the recommended action level range presented in USEPA guidance for an industrial setting (see *A Guide on Remedial Actions at Superfund Sites with PCB Contamination* [USEPA, 1990]). (The upper end of the action level range is 25 mg/kg.) The PRGs for 1,2,4-TCB (330 mg/kg) and Aroclor 1254 (7 mg/kg) represent a hazard index (HI) of 1, and are less than (more restrictive than) the PRGs representing the 1×10^{-5} cancer risk levels.

Subsurface soil preliminary remediation goals—PRGs for the construction worker exposure scenario were calculated for all subsurface soil COC; these goals are presented in the *Technical Memorandum – Mr. Tom D. Blackman to Ms. Ruth Prince and Mr. James R. Carroll, Preliminary Remediation Goals for Industrial and Construction Workers, Block E Soil Remediation,* (Lockheed Martin, March 2018). The PRGs for BaPEq (10 mg/kg), Aroclor 1254 (7 mg/kg), 1,2,4-TCB (530 mg/kg), and TCE (3.9 mg/kg) represent a hazard index (HI) of 1 and are less than (more restrictive than) the PRGs representing the 1×10^{-5} cancer risk levels. The PRG for Aroclor 1260 (58 mg/kg) represents the 1×10^{-5} cancer risk level.

Step 3: Ranking of locations:

Sampling locations for Block E surface soil and the five Block E subsurface soil EUs were ranked according to calculated risk levels. Surface soil (i.e., soil from the ground surface to two feet bgs) locations were ranked separately from subsurface soil (i.e., soil between two and 20 feet bgs). If more than one soil sample was available for the depth interval, the maximum risk was used to rank the location. The results of the ranking for surface and subsurface soil are presented in the detailed baseline risk analysis tables in Attachment B (Tables B-1 to B-6). The ranking from high to low is based on the calculation of sampling location-specific total cancer risk and HI estimates for all COPC identified in Step 1 (not just COC). Table B-1 presents the sampling location risk ranking for the hypothetical typical industrial worker exposed to surface soil; Tables B-2 to B-6 present this analysis for construction workers exposed to the five subsurface soil EUs, respectively.

Step 4: Iteratively remove samples and recalculate exposure point concentration:

The information presented for Block E in the Attachment B tables was reviewed to select an initial set of locations for the RRA. All locations meeting the MDE "hot spot" definition (see page 1-1) were automatically identified as being targeted for remediation. Next, the locations contributing most significantly to calculated risk estimates (using professional judgment) for evaluated receptors were considered targeted for remediation. The selected data points (assuming removal via excavation) were replaced by "backfill" soil concentrations and the EPC (equal to the 95% upper confidence limit [UCL] on the arithmetic mean) for each COC was recalculated using the substituted concentrations. Chemical concentrations in the backfill used at Block H were used as the substitute concentrations as presented in Table 2-1 (Tetra Tech, 2016). If the recalculated EPC exceeded the PRG for a receptor, additional locations were removed iteratively (one at a time)

from the data set and replaced with the substitute concentration. The EPC was then recalculated until the resultant EPC was equal to or less than the PRG. Tables 2-2 and 2-3 present a summary of the samples identified for removal from Block E surface soil and subsurface soil, respectively; sampling location-specific risk results are found on the tables in Attachment B.

Step 5: Margin of safety:

Given the large data sets for some of the EUs under evaluation, locations with highly elevated concentrations could be "diluted out" by a large number of locations with low concentrations. To prevent this, "safety limits" were also used to identify sampling locations requiring remediation. For surface soil, all locations with Aroclor 1254 and Aroclor 1260 concentrations greater than 25 mg/kg were also targeted for removal. As previously discussed, 25 mg/kg is the upper end of the action level range for industrial exposures (USEPA, 1990). For subsurface soil, all locations with Aroclor 1254 and Aroclor 1260 concentrations greater than 100 mg/kg were also targeted for removal. The value of 100 mg/kg is the upper end of the range (25–100 mg/kg) for low occupancy soils (40 CFR 761, Subpart D). Tables 2-2 and 2-3 also list sampling locations recommended for removal based on exceeding the surface soil and subsurface soil PCB safety limits, respectively.

Step 6: Address cumulative risk issue:

Samples were removed from the data set until the 95% UCLs for the COC were below their respective PRGs. All samples with Aroclor 1254 and Aroclor 1260 concentrations above the safety limits were removed. As a final check, receptor-specific risk estimates were recalculated for all COPC identified in Step 1 (not just COC) to ensure that cumulative risk estimates were equal to or below the 1×10^{-5} cancer risk level and less than a HI of 1. The risk assessment of predicted post-removal soil concentrations of all COPC is in Attachment C. Tables C.6-1–C.6-6. present the results of the reasonable maximum exposure (RME) risks, and show that predicted cumulative risk estimates are less than 1×10^{-5} and summed HIs are less than or equal to 1 for industrial workers exposed to surface soil and for construction workers exposed to subsurface soil in each subarea.

SECTION 3
RESULTS AND CONCLUSIONS

The residual risk analysis (RRA) described in Section 2 is a six-step process applied to each soil data set that (1) identifies chemicals of concern (risk drivers), (2) identifies preliminary remediation goals (PRGs), (3) ranks sampling result locations from highest risk to lowest, (4) iteratively removes samples from the data set and calculates exposure point concentrations (EPCs) from the remaining sampling results, (5) identifies additional sampling locations for removal based upon a comparison to margin of safety concentrations, and (6) recalculates cumulative risk using remaining soil sampling results to confirm achievement of risk management goals.

The sampling locations that the residual risk analysis targeted for removal to achieve risk management goals are summarized in Table 2-2 (for the industrial worker exposed to surface soil) and Table 2-3 (for the construction worker receptor exposed to subsurface soil). Note that all sampling locations meeting the Maryland Department of the Environment (MDE) "hot spot" definition were re-identified for removal (see Attachment B tables). The following summarizes the information presented in Tables 2-2 and 2-3, detailed tables for the RRA (Attachment B), and in the cumulative risk assessment (Attachment C):

- Table B-1 shows results for the residual risk analysis for Block E surface soil. Polychlorinated biphenyls (PCBs) [Aroclor 1260] are the predominant chemicals of concern (COC). Fifty-four locations are targeted for remediation to achieve Maryland Department of the Environment (MDE) risk management goals (i.e., a cumulative cancer-risk level of 1×10^{-5} [i.e., a one-in-100,000 excess probability of developing cancer] and cumulative hazard index [HI] of 1) for the industrial worker. Remediating this soil will result in a 95% upper confidence limit (or exposure point concentration [EPC]) of less than 10 milligrams per kilogram (mg/kg) for polychlorinated biphenyls. As an additional margin of safety, all surface soil locations with polychlorinated biphenyl concentrations exceeding 25 mg/kg (an additional 52 sampling locations) are also targeted for remediation (see Table 2-2). As noted above, the recommended action level range for polychlorinated biphenyls set forth in United States Environmental Protection Agency (USEPA) guidance for an industrial setting (see A Guide on Remedial Actions at Superfund Sites with PCB Contamination [USEPA, 1990]) is 10–25 mg/kg. The highest remaining Aroclor 1260

concentration in the analysis is 24 mg/kg, and the highest remaining Aroclor 1254 concentration in the analysis is 20 mg/kg. The residual cancer risk for an industrial worker exposed to surface soil is 3×10^{-6} with a hazard index of 0.2.

- Table B-2 shows the residual risk analysis results for the Block E subsurface soil, excluding the other four subareas. No locations are targeted for remediation to achieve Maryland Department of the Environment risk management benchmarks. The concentration of all COC are less than the PRGs. The highest Aroclor 1260 concentration is 22 mg/kg, and the highest Aroclor 1254 concentration is 0.038 J mg/kg. The cancer risk for a construction worker exposed to subsurface soil is 5×10^{-7}, with a hazard index of 0.7.

- Table B-3 shows the residual risk analysis results for Block E subsurface soil at the Transformer #2 Subarea. Three locations are targeted for remediation to achieve Maryland Department of the Environment risk-management benchmarks. As an additional margin of safety, six additional locations with Aroclor 1260 concentrations exceeding 100 mg/kg are also targeted for remediation. The highest remaining Aroclor 1260 concentration is 31 mg/kg, and the highest remaining Aroclor 1254 concentration is 0.095 mg/kg. The residual cancer risk for a construction worker exposed to subsurface soil is 9×10^{-7} with a hazard index of 0.5.

- Table B-4 shows the residual risk analysis results for Block E subsurface soil at the Transformer #3 Subarea. Eleven locations are targeted for remediation to achieve Maryland Department of the Environment risk management benchmarks. As an additional margin of safety, ten additional locations with Aroclor 1260 concentrations exceeding 100 mg/kg are also targeted for remediation. The highest remaining Aroclor 1260 concentration in the analysis is 65 mg/kg, and Aroclor 1254 is non-detect. The residual cancer risk to a construction worker exposed to subsurface soil is 9×10^{-7}, and the hazard index is 0.4.

- Table B-5 shows the residual risk analysis results for Block E subsurface soil at the Transformer Room #4 Subarea. Fifteen locations are targeted for remediation to achieve Maryland Department of the Environment risk management benchmarks. An additional 16 locations are predicted to have Aroclor 1260 concentrations exceeding 100 mg/kg; they are also targeted for remediation, as a margin of safety. The highest remaining Aroclor 1260 concentration is 50 mg/kg, and Aroclor 1254 is non-detect. Two locations targeted for remediation are predicted to have 1,2,4-trichlorobenzene concentrations exceeding the preliminary remedial goal of 530 mg/kg. One location targeted for removal is predicted to have a benzo(a)pyrene equivalent concentration exceeding the preliminary remedial goal of 10 mg/kg. The residual cancer risk for a construction worker exposed to subsurface soil is 1×10^{-6} and the hazard index is 0.9.

- Table B-6 shows the residual risk analysis results for the Southeast Subarea. Seven locations are targeted for remediation to achieve MDE risk management benchmarks. An additional three locations are predicted to have Aroclor 1254 concentrations exceeding 100 mg/kg, and as a margin of safety are targeted for remediation. The highest remaining Aroclor 1260 concentration is 24 mg/kg and the highest remaining Aroclor 1254

concentration is 80 mg/kg. Three locations targeted for remediation have trichloroethene concentrations exceeding the preliminary remedial goal of 3.9 mg/kg. The residual cancer risk for a construction worker exposed to subsurface soil is 1×10^{-6} and the hazard index is 1.

The conclusions above should be reviewed in light of the following caveats and uncertainties:

- Data for the Lockheed Martin Middle River Complex facility do not include a site-specific background data set for soil. The risk-based preliminary remedial goal calculated for benzo(a)pyrene equivalents is within the range of anthropogenic (human caused) background soil concentrations reported in the literature. Site environs are highly developed; therefore, the risk-based preliminary remedial goal might actually be less than anthropogenic background concentrations, and thus considered conservative.

- The chemical profile of the fill material used in Block H (Table 2-1) was used as replacement concentrations for locations targeted for remediation when calculating exposure point concentrations. Volatile organic compounds and polychlorinated biphenyls have not been detected in the fill material. The concentration of benzo(a)pyrene equivalents in fill material is 9.82 micrograms per kilogram (µg/kg), which is within the range of anthropogenic background values. The exposure point concentration (i.e., the 95% upper confidence level on the arithmetic mean) and residual risk will need to be recalculated if the chemical profile of the soil fill material used for Block E after remediation is significantly different than that used for replacement concentrations in this evaluation.

In summary, a residual risk analysis ranked soil sampling locations in Block E from highest to lowest risk. Sampling locations with chemical of concern concentrations higher than the risk-based preliminary remedial goals were iteratively targeted for remediation in the analysis, and the exposure point concentrations were recalculated (assuming the location would be excavated) until the exposure point concentration was equal to or less than the preliminary remedial goal. Preliminary remedial goals for industrial workers and construction workers were used for Block E surface and subsurface soil, respectively. Soil volumes calculated using the locations selected in the residual risk analysis are lower than soil volumes calculated using a strict comparison of sampling location concentrations to preliminary remedial goals, because not every sampling location with exceedances will need to be remediated. The final benchmark or remedial action objective is to achieve a cumulative residual cancer risk level not exceeding 1×10^{-5}, and a hazard index not exceeding 1 for industrial workers (exposed to surface soil in Block E) and construction workers (exposed to subsurface soil in Block E). Risk estimates calculated for these receptors using residual concentrations (as determined by this residual risk analysis) do not exceed Maryland

Department of the Environment risk management benchmarks for cancer (1×10^{-5}) and non-cancer (i.e., a hazard index > 1) effects.

Table 2-1

Chemical Concentrations In Backfill
Lockheed Martin, Middle River Complex
Middle River, Maryland

Chemical	Concentration in Backfill
Volatile organic compounds (µg/kg)	
1,2,3-Trichlorobenzene	0.4 U
1,2,4-Trichlorobenzene	0.28 U
1,2,4-Trimethylbenzene	0.68 U
1,2-Dichloroethane	0.36 U
1,3-Dichlorobenzene	0.37 U
1,4-Dichlorobenzene	0.69 U
Ethylbenzene	0.27 U
Total Xylenes	0.37 U
Trichloroethene	0.44 U
Vinyl Chloride	0.41 U
Polycyclic aromatic hydrocarbons (µg/kg)	
Benzo(a)pyrene Equivalents	9.82
Naphthalene	0.2 U
Polychlorinated biphenyls (µg/kg)	
Aroclor 1242	12 U
Aroclor 1248	8.6 U
Aroclor 1254	15 U
Aroclor 1260	9.7 U
Metals (mg/kg)	
Antimony	0.43 U
Arsenic	0.4 J
Cobalt	0.054 J
Mercury	0.015 U
Thallium	0.12 U
Vanadium	21
Hexavalent Chromium(1)	0.55

Notes:
1 - Fill material was not analyzed for hexavalent chromium.
Value is 5 percent of the total chromium result.
µg/kg - microgram per kilogram
mg/kg - milligram per kilogram
U - Not detected.
J - Value is less than reporting limit but greater than or equal to the method detection limit and the concentration is an approximate value.

E-SB-1722			310 U	25,000

µg/kg - micrograms per kilogram
BaPEq - benzo(a)pyrene equivalents
COC - chemicals of concern
J - estimated value
K - biased high
TCB - trichlorobenzene
U - not detected
UCL - upper confidence limit

Table 2-3

Summary of Sample Locations Identified for Remediation - Block E Subsurface Soil
Lockheed Martin, Middle River Complex
Middle River, Maryland

Location	1,2,4-TCB (µg/kg)	BaPEq Concentration (µg/kg)	Aroclor 1254 (µg/kg)	Aroclor 1260 (µg/kg)
Subsurface Soil Excluding Four Subareas				
No samples were identified to be removed in subsurface soil excluding the four subareas.				
Transformer Room # 2 Subarea				
Removal of subsurface soil from these locations achieves acceptable 95% UCL for COC.				
E-SB-1499			810,000 U	9,400,000
E-SB-1494			810,000 U	2,300,000
E-SB-1740			17,000 U	1,100,000
The following remaining subsurface soil locations have PCB concentrations exceeding 100 mg/kg.				
E-SB-1495			86,000 U	730,000
E-SB-1616			9,300 U	340,000
E-SB-1447			17,000 U	290,000
E-SB-1617		145	8,000 U	240,000
E-SB-1620			3,500 U	200,000
E-SB-1613			3,200 U	190,000
Transformer Room #3 Subarea				
Removal of subsurface soil from these locations achieves acceptable 95% UCL for COC.				
E-SB-1501			1,600,000 U	7,700,000
E-SB-1503			1,700,000 U	7,000,000

E-SB-852			69 U	120,000

µg/kg - micrograms per kilogram
BaPEq - benzo(a)pyrene equivalents
COC - chemicals of concern
J - estimated value
mg/kg - milligrams per kilogram
PCB - polychlorinated biphenyls
TCB - trichlorobenzene
U - not detected
UCL - upper confidence limit

Table 2-3

Summary of Sample Locations Identified for Remediation - Block E Subsurface Soil
Lockheed Martin, Middle River Complex
Middle River, Maryland

Location	1,2,4-TCB (µg/kg)	TCE (µg/kg)	BaPEq Concentration (µg/kg)	Aroclor 1254 (µg/kg)	Aroclor 1260 (µg/kg)
Southeast Subarea					
Removal of subsurface soil from these locations achieves acceptable 95% UCL for COC.					
E-SB-1713				3,500,000 J	41,000 U
E-VB-11	9,100 B	7,500,000	2,540	400 U	1400
E-SB-1456				1,700,000	100,000 U
E-SB-1751				1,100,000	42,000 U
E-SB-1378				450,000	8,900 U
E-SB-1028	580 U	730,000	24.9	39 U	360
E-SB-1027	42 U	50,000	70.2	20 U	110
Three remaining subsurface soil locations with PCB concentrations exceeding 100 mg/kg (=100,000 µg/kg).					
E-VB-04				260,000	19,000 U
E-VB-01				150,000	9,300 U
E-SB-1448				130,000	10,000 U

µg/kg - micrograms per kilogram
BaPEq - benzo(a)pyrene equivalents
COC - chemicals of concern
J - estimated value
mg/kg - milligrams per kilogram
TCB - trichlorobenzene
TCE - trichloroethene
U - not detected
UCL - upper confidence limit

Table B-1

Residual Risk Analysis Results - Block E - Surface Soil
Lockheed Martin, Middle River Complex
Middle River, Maryland

1 - Sample locations are listed in order from highest to lowest cancer risk.
2 - One half the non-detected value was used for the calculation of benzo(a)pyrene equivalents. If all concentrations were non-detect then the detection limit for benzo(a)pyrene was used as the benzo(a)pyrene equivalent concentration. Original and duplicate samples were averaged when calculating the benzo(a)pyrene equivalent concentration.
3 - Total incremental lifetime cancer risk (ILCR) from exposure to all chemicals of potential concern in soil.
4 - Total hazard index from exposure to all chemicals of potential concern in soil.

A blank space in the concentration column indicates the sample was not analyzed for that parameter.

Shading indicates ILCR exceeds $1x10^{-4}$ or HI exceeds 100 and location is considered to be a "hot spot" according to Maryland Department of Environmental Protection guidance (MDE, 2008).

Samples identified for removal are bolded and italicized.

Red shading indicates Aroclor concentration exceeds safety limit of 25,000 µg/kg.

Sample IDs ending in "AVG" indicate an original sample and duplicate was collected at this depth interval. The average of the original and duplicate sample analytical results are presented.

B - analyte found in blank associated with this sample
1,2,4-TCB - 1,2,4-trichlorobenzene
BaPEq - benzo(a)pyrene equivalent
HI - hazard index
ILCR - incremental lifetime cancer risk
J - estimated value
K - biased high
L - biased low
PRG - preliminary remedial goal
U - not detected
UCL - upper confidence level
µg/kg - microgram per kilogram

Table B-2

Residual Risk Analysis Results - Block E - Subsurface Soil Excluding Four Subareas
Lockheed Martin, Middle River Complex
Middle River, Maryland

Location[1]	Sample ID	Depth (feet)	1,2,4-TCB (µg/kg)	BaPEq Concentration[2] (µg/kg)	Aroclor 1254 (µg/kg)	Aroclor 1260 (µg/kg)	Construction Worker		Comments
							Total ILCR[3]	Total HI[4]	
E-SB-1720	E-SB-1720-10-12	10 - 12			1,000 U	22,000	2.8E-06	6.8E-02	
SB-504	SB-504-0406	4 - 6	0.95 B	2,167	1,900 U	11,000	2.1E-06	8.6E-01	No samples are needed to be removed to meet PRGs for construction workers exposed to 1,2,4-TCB (530,000 µg/kg or 530 mg/kg), BaPEq (10,000 µg/kg or 10 mg/kg), Aroclor 1254 (7,000 ug/kg or 7 mg/kg), and Aroclor 1260 (58,000 ug/kg or 58 mg/kg) and a cumulative cancer risk level of $1x10^{-5}$. Maximum detected concentrations of 1,2,4-TCB (1,800 µg/kg), BaPEq (2,170 µg/kg), Aroclor-1254 (38 J µg/kg) and Aroclor-1260 (22,000 µg/kg) are less than their respective PRGs. Site 95% UCLs are 1,2,4-TCB (223 µg/kg), BaPEq (164 ug/kg), Aroclor 1254 (2.3 ug/kg), and Aroclor 1260 (500 ug/kg). The residual ILCR would be $5x10^{-7}$ and the residual cumulative HI would be 0.7.

1 - Sample locations are listed in order from highest to lowest cancer risk.
2 - One half the non-detected value was used for the calculation of benzo(a)pyrene equivalents. If all concentrations were non-detect then the detection limit for benzo(a)pyrene was used as the benzo(a)pyrene equivalent concentration. Original and duplicate samples were averaged when calculating the benzo(a)pyrene equivalent concentration.
3 - Total incremental lifetime cancer risk from exposure to all chemicals of potential concern in soil.
4 - Total hazard index from exposure to all chemicals of potential concern in soil.

A blank space in the concentration column indicates the sample was not analyzed for that parameter.

Sample IDs ending in "AVG" indicate an original sample and duplicate was collected at this depth interval. The average of the original and duplicate sample analytical results are presented.

B - analyte found in blank associated with this sample
1,2,4-TCB - 1,2,4-trichlorobenzene
BaPEq - benzo(a)pyrene equivalent
HI - hazard index
ILCR - incremental lifetime cancer risk
J - estimated value
L - biased low
PRG - preliminary remedial goal
U - not detected
UCL - upper confidence level
µg/kg - microgram per kilogram

Table B-3

Residual Risk Analysis Results - Block E - Subsurface Soil (2 to 20 Feet) - Transformer Room #2 Subarea

	E-SB-1614-18-20	18 - 20		16 U	21 U	2.3E-09	1.1E-03	

1 - Sample locations are listed in order from highest to lowest Aroclor 1260 concentrations.
2 - One half the non-detected value was used for the calculation of benzo(a)pyrene equivalents. If all concentrations were non-detect then the detection limit for benzo(a)pyrene was used as the benzo(a)pyrene equivalent concentration. Original and duplicate samples were averaged when calculating the benzo(a)pyrene equivalent concentration.
3 - Total incremental lifetime cancer risk from exposure to all chemicals of potential concern in soil.
4 - Total hazard index from exposure to all chemicals of potential concern in soil.

A blank space in the concentration column indicates the sample was not analyzed for that parameter.

Gray shading indicates ILCR exceeds $1x10^{-4}$ or HI exceeds 100 and location is considered to be a "hot spot" according to Maryland Department of Environmental Protection guidance (MDE, 2008).

Samples identified for removal are bolded and italicized.

Red shading indicates Aroclor concentration exceeds safety limit of 100,000 µg/kg.

Sample IDs ending in "AVG" indicate an original sample and duplicate was collected at this depth interval. The average of the original and duplicate sample analytical results are presented.

B - analyte found in blank associated with this sample
1,2,4-TCB - 1,2,4-trichlorobenzene
BaPEq - benzo(a)pyrene equivalent
HI - hazard index
ILCR - incremental lifetime cancer risk
J - estimated value
PRG - preliminary remedial goal
U - not detected
UCL - upper confidence level
µg/kg - microgram per kilogram

Table B-4

Residual Risk Analysis Results - Block E - Subsurface Soil (2 to 20 Feet) - Transformer Room #3 Subarea
Lockheed Martin, Middle River Complex
Middle River, Maryland

1 - Sample locations are listed in order from highest to lowest cancer risk.
2 - One half the non-detected value was used for the calculation of benzo(a)pyrene equivalents. If all concentrations were non-detect then the detection limit for benzo(a)pyrene was used as the benzo(a)pyrene equivalent concentration. Original and duplicate samples were averaged when calculating the benzo(a)pyrene equivalent concentration.
3 - Total incremental lifetime cancer risk from exposure to all chemicals of potential concern in soil.
4 - Total hazard index from exposure to all chemicals of potential concern in soil.

A blank space in the concentration column indicates the sample was not analyzed for that parameter.

Gray shading indicates ILCR exceeds $1x10^{-4}$ or HI exceeds 100 and location is considered to be a "hot spot" according to Maryland Department of Environmental Protection guidance (MDE, 2008).

Red shading indicates Aroclor concentration exceeds safety limit of 100,000 µg/kg.

Samples identified for removal are bolded and italicized.

Sample IDs ending in "AVG" indicate an original sample and duplicate was collected at this depth interval. The average of the original and duplicate sample analytical results are presented.

B - analyte found in blank associated with this sample
1,2,4-TCB - 1,2,4-trichlorobenzene
BaPEq - benzo(a)pyrene equivalent
HI - hazard index
ILCR - incremental lifetime cancer risk
J - estimated value
PRG - preliminary remedial goal
U - not detected
UCL - upper confidence level
µg/kg - microgram per kilogram

Table B-5

Residual Risk Analysis Results - Block E - Subsurface Soil (2 to 20 Feet) - Transformer Room #4 Subarea
Lockheed Martin, Middle River Complex
Middle River, Maryland

Location[1]	Sample ID	Depth (feet)	1,2,4-TCB (µg/kg)	BaPEq Concentration[2] (µg/kg)	Aroclor 1254 (µg/kg)	Aroclor 1260 (µg/kg)	Construction Worker		Comments
							Total ILCR[3]	Total HI[4]	
Samples Needing Removal to Achieve an 95% UCL that Meets PRGs.									
E-SB-1547	***E-SB-1547-2-4***	*2 - 4*			*340,000 U*	*37,000,000*	*4.7E-03*	*2.3E+01*	Samples needing removal to meet PRGs for construction workers exposed to 1,2,4-TCB (530,000 µg/kg or 530 mg/kg), BaPEq (10,000 µg/kg or 10 mg/kg), Aroclor 1254 (7,000 µg/kg or 7 mg/kg), and Aroclor 1260 (58,000 µg/kg or 58 mg/kg) and a cumulative cancer risk level of $1x10^{-5}$. Site 95% UCLs are 1,2,4-TCB (125,000 µg/kg), BaPEq (34 µg/kg) and Aroclor 1260 (35,800 µg/kg). Aroclor 1254 was not detected. The residual ILCR would be $6x10^{-6}$ and the residual cumulative HI would be 1.

Table B-5

Residual Risk Analysis Results - Block E - Subsurface Soil (2 to 20 Feet) - Transformer Room #4 Subarea
Lockheed Martin, Middle River Complex
Middle River, Maryland

1 - Sample locations are listed in order from highest to lowest cancer risk.
2 - One half the non-detected value was used for the calculation of benzo(a)pyrene equivalents. If all concentrations were non-detect then the detection limit for benzo(a)pyrene was used as the benzo(a)pyrene equivalent concentration. Original and duplicate samples were averaged when calculating the benzo(a)pyrene equivalent concentration.
3 - Total incremental lifetime cancer risk from exposure to all chemicals of potential concern in soil.
4 - Total hazard index from exposure to all chemicals of potential concern in soil.

A blank space in the concentration column indicates the sample was not analyzed for that parameter.

Gray shading indicates ILCR exceeds $1x10^{-4}$ or HI exceeds 100 and location is considered to be a "hot spot" according to Maryland Department of Environmental Protection guidance (MDE, 2008).

Samples identified for removal are bolded and italicized.

Red shading indicates Aroclor concentration exceeds safety limit of 100,000 µg/kg.

Sample IDs ending in "AVG" indicate an original sample and duplicate was collected at this depth interval. The average of the original and duplicate sample analytical results are presented.

B - analyte found in blank associated with this sample
1,2,4-TCB - 1,2,4-trichlorobenzene
BaPEq - benzo(a)pyrene equivalent
HI - hazard index
ILCR - incremental lifetime cancer risk
J - estimated value
PRG - preliminary remedial goal
U - not detected
UCL - upper confidence level
µg/kg - microgram per kilogram

Table B-6

Residual Risk Analysis Results - Block E - Subsurface Soil (2 to 20 Feet) - Southeast Subarea
Lockheed Martin, Middle River Complex
Middle River, Maryland

1 - Sample locations are listed in order from highest to lowest cancer risk.
2 - One half the non-detected value was used for the calculation of benzo(a)pyrene equivalents. If all concentrations were
Samples Needing Removal to Achieve an 95% UCL that Meets PRGs.
and duplicate samples were averaged when calculating the benzo(a)pyrene equivalent concentration.
3 - Total incremental lifetime cancer risk from exposure to all chemicals of potential concern in soil.
4 - Total hazard index from exposure to all chemicals of potential concern in soil.

A blank space in the concentration column indicates the sample was not analyzed for that parameter.

Gray shading indicates ILCR exceeds $1x10^{-4}$ or HI exceeds 100 and location is considered to be a "hot spot" according to Maryland Department of Environmental Protection guidance (MDE, 2008).

Samples identified for removal are bolded and italicized.

Red shading indicates Aroclor concentration exceeds safety limit of 100,000 µg/kg.

Sample IDs ending in "AVG" indicate an original sample and duplicate was collected at this depth interval. The average of the original and duplicate sample analytical results are presented.

B - analyte found in blank associated with this sample
1,2,4-TCB - 1,2,4-trichlorobenzene
BaPEq - benzo(a)pyrene equivalent
HI - hazard index
ILCR - incremental lifetime cancer risk
J - estimated value
PRG - preliminary remedial goal
TCE - Trichloroethene
U - not detected
UCL - upper confidence level
µg/kg - microgram per kilogram

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - No background data are available.
5 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, May 2018. The noncarcinogenic values (denoted with a "N" flag) correspond to a target hazard quotient of 0.1. Carcinogenic values represent an incremental cancer risk of 1.0E-06 (carcinogens denoted with a "C" flag).
6 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
7 - Value is for 1,4-dichlorobenzene.
8 - Value is for m-xylene.
9 - Value is for 3-methylphenol.
10 - Value is for acenaphthene.
11 - Value is for benzo(a)pyrene.
12 - Value is for pyrene.
13 - Value is for Aroclor 1260.
14 - Value is for high risk PCBs.
15 - Value is for trivalent chromium.
16 - Value is for mercuric chloride (and other mercury salts).
Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Definitions:
ARAR/TBC = Applicable or Relevant and Appropriate Requirements To Be Considered
C = Carcinogen
COPC = Chemical Of Potential Concern
J = Estimated value
K = Biased high
L = Biased low
mg/kg = milligrams per kilogram
N = Noncarcinogen
NA = Not Applicable/Not Available
ug/kg = micrograms per kilogram

Rationale Codes:
For selection as a COPC:
ASL = Above Screening Level

For elimination as a COPC:
BSL = Below COPC Screening Level
NTX = No toxicity criteria

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - No background data are available.
5 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, May 2018. The noncarcinogenic values (denoted with a "N" flag) correspond to a target hazard quotient of 0.1. Carcinogenic values represent an incremental cancer risk of 1.0E-06 (carcinogens denoted with a "C" flag).
6 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
7 - Value is for 1,4-dichlorobenzene.
8 - Value is for m-xylene.
9 - Value is for acenaphthene.
10 - Value is for benzo(a)pyrene.
11 - Value is for pyrene.
12 - Value is for endosulfan.
13 - Value is for endrin.
14 - Value is for high risk PCBs.
15 - Value is for trivalent chromium.
16 - Value is for mercuric chloride (and other mercury salts).
17 - Value is for 3-methylphenol.
Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Definitions:
ARAR/TBC = Applicable or Relevant and Appropriate Requirements To Be Considered
C = Carcinogen
COPC = Chemical Of Potential Concern
J = Estimated value
K = Biased high
L = Biased low
mg/kg = milligrams per kilogram
N = Noncarcinogen
NA = Not Applicable/Not Available
ug/kg = micrograms per kilogram

Rationale Codes:
For selection as a COPC:
ASL = Above Screening Level

For elimination as a COPC:
BSL = Below COPC Screening Level
NTX = No toxicity criteria

CLIENT: LOCKHEED MARTIN - BLOCK E		**JOB NUMBER:** 112IC07931
SUBJECT: CALCULATION OF PARTICULATE EMISSION FACTOR FOR CONSTRUCTION WORKERS FROM VEHICULAR TRAFFIC		
BASED ON: Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites (USEPA, December 2002)		
BY: R. JUPIN	**CHECKED BY:**	**DATE:** 4/09/2018

RELEVANT EQUATIONS:

$$PEF_{sc} = Q \Big/ C_{sr} \times \frac{1}{F_D} \times \frac{T \times A_R}{\frac{2.6 \times (s/12)^{0.8} (W/3)^{0.4}}{(M_{dry}/0.2)^{0.3}} \times \left[\frac{(365\text{-}p)}{365}\right] \times 281.9 \times \sum VKT}$$

$$T = ET \times EF \times 3600\ s/hr \qquad A_R = L_R \times W_R \times 0.092903\ m^2/ft^2$$

$$W = [(N_{car} \times W_{car}) + (N_{truck} + W_{truck})]/(N_{car} + N_{truck})$$

$$VKT = (N_{car} + N_{truck}) \times (L_R \times 0.0003048\ ft/km) \times EF$$

$$F_D = 0.1852 + \frac{5.3537}{T} + \frac{-9.6318}{T^2}$$

$$Q/C_{sr} = A \times \exp\left[\frac{(\ln A_s - B)^2}{C}\right]$$

Where:

T = :	7.2E+06	total time over which construction occurs (s)
ET = :	8	Exposure time (hr/day)
EF = :	250	Number of days construction occurs (days)
W_R = :	20	width of road segment (ft)
As = :	0.5	surface area of contaminated road segment (acres)
L_R = :	147.580	length of road segment (ft)
A_R = :	274.213	surface area of contaminated road segment (m^2)
s =:	8.5	road surface silt content (%)
Mdry = :	0.2	road surface material moisture content under dry conditions, uncontrolled conditions (%)
N_{car} = :	20	number of cars
N_{truck} = :	10	number of trucks
W_{car} = :	2	tons/car
W_{truck} = :	20	tons/truck
p = :	140	days per year with at least 0.1" of precipitation
W = :	8	mean vehicle weight (tons)
VKT = :	337.37	sum of fleet vehicle km traveled (km)
F_D= :	0.185	dispersion correction factor (unitless)
A = :	12.9351	
B = :	5.7383	
C = :	71.7711	
Q/C_{sr} = :	23.018	inverse of the ratio of the geometric mean air
PEF_{sc} = :	1.43E+06	Particulate emission factor (m^3/kg)
