TABLE OF CONTENTS

Section **Page**

ACRONYMS ..... **ix**

1 INTRODUCTION **1-1**

2 SITE BACKGROUND **2-1**

2.1 LOCATION AND HISTORY 2-1

2.1.1 Martin State Airport 2-1

2.1.2 Strawberry Point and Greater Strawberry Point Facility 2-2

2.2 PHYSICAL FEATURES 2-4

2.2.1 Land Use 2-4

2.2.2 Climate 2-5

2.2.3 Physiography 2-5

2.2.4 Topography 2-5

2.2.5 Surface Water Hydrology 2-6

2.2.6 Regional Geologic and Hydrogeologic Conditions 2-8

2.2.7 Vicinity Subsurface Conditions 2-9

2.3 SUMMARY OF PREVIOUS INVESTIGATIONS 2-11

2.3.1 Strawberry Point Phase I Investigations 2-11

2.3.2 2008 Phase II Investigations at REC #1 2-12

2.3.3 2010 Phase II Site Investigation 2-14

2.4 CURRENT SITE CONDITIONS AND OPERATIONS 2-16

3 INVESTIGATION APPROACH AND METHODOLOGY **3-1**

3.1 MOBILIZATION/DEMOBILIZATION 3-3

3.2 TEST PITS 3-5

3.3 DPT INVESTIGATION 3-6

3.4 MONITORING WELL INSTALLATION 3-8

3.5 GROUNDWATER MONITORING WELL PURGING AND SAMPLING 3-9

3.6 QUALITY CONTROL SAMPLES, DOCUMENTATION, AND CUSTODY 3-10

3.7 SAMPLE NOMENCLATURE 3-11

3.8 SURVEYING 3-11

TABLE OF CONTENTS (continued)

Section **Page**

3.9 SYNOPTIC WATER LEVEL MEASUREMENTS 3-11
3.10 WASTE MANAGEMENT 3-12

4 RESULTS 4-1
4.1 GEOLOGY AND HYDROLOGY 4-2
4.1.1 Geology 4-2
4.1.2 Hydrology 4-3
4.2 TEST PIT INVESTIGATION RESULTS 4-3
4.2.1 Test Pits in RECs #8 and #9 Areas 4-4
4.2.2 Test Pits in REC #10 Area 4-6
4.3 SOIL BORING AND SOIL SAMPLING RESULTS 4-8
4.3.1 Borings in REC #8, REC #9 and REC #10 Area 4-9
4.3.2 Borings in REC #11 Area 4-14
4.4 GROUNDWATER RESULTS 4-17
4.4.1 RECs #8, #9, and #10 Groundwater Results 4-17
4.4.2 RECs #11 Groundwater Results 4-19

5 HUMAN HEALTH RISK ASSESSMENT 5-1
5.1 DATA EVALUATION 5-3
5.1.1 Data Usability 5-3
5.1.2 Selection of Chemicals of Potential Concern 5-4
5.1.3 COPC Selected for the HHRA 5-9
5.2 EXPOSURE ASSESSMENT METHODOLOGY 5-14
5.2.1 Conceptual Site Model 5-14
5.2.2 Central Tendency Exposure versus Reasonable Maximum Exposure 5-21
5.2.3 Exposure Point Concentrations 5-21
5.2.4 Chemical Intake Estimation 5-23
5.3 TOXICITY ASSESSMENT 5-38
5.3.1 Toxicity Criteria for Oral and Inhalation Exposures 5-38
5.3.2 Toxicity Criteria for Dermal Exposure 5-39
5.3.3 Inhalation Toxicity Values for Construction Workers 5-40
5.3.4 Chromium Toxicity 5-40

TABLE OF CONTENTS (continued)

Section **Page**

5.3.5 Toxicity of PCBs 5-41
5.3.6 Toxicity Criteria for the Carcinogenic Effects of PAHs 5-42
5.3.7 Carcinogenic Toxicity Criteria for Trichloroethene 5-42
5.3.8 Carcinogenic Toxicity Criteria for Vinyl Chloride 5-43
5.4 RISK CHARACTERIZATION 5-44
5.4.1 Quantitative Analysis of Constituents other than Lead 5-44
5.4.2 Interpretation of Risk Assessment Results 5-45
5.4.3 Risk Characterization Results 5-46
5.5 UNCERTAINTY ANALYSIS 5-65
5.5.1 Uncertainty in COPC Selection 5-66
5.5.2 Exposure Assessment Uncertainty 5-72
5.5.3 Uncertainty in the Toxicological Evaluation 5-73
5.5.4 Uncertainty in the Risk Characterization 5-80
5.6 REMEDIAL GOAL OPTIONS 5-81
5.7 SUMMARY 5-81

6 ECOLOGICAL RISK ASSESSMENT 6-1
6.1 INTRODUCTION 6-1
6.2 PROBLEM FORMULATION 6-1
6.2.1 Environmental Setting 6-2
6.2.2 Potential Sources of Contamination 6-3
6.2.3 Potential Exposure Pathways 6-3
6.2.4 Endpoints 6-4
6.2.5 Conceptual Site Model 6-6
6.3 ECOLOGICAL EFFECTS EVALUATION 6-7
6.3.1 Terrestrial Plants and Invertebrates 6-7
6.3.2 Aquatic Organisms 6-8
6.3.3 Terrestrial Wildlife 6-8
6.4 EXPOSURE CHARACTERIZATION 6-9
6.5 RISK CHARACTERIZATION 6-10

ACRONYMS

θ_w	water filled soil porosity
θ_a	air filled soil porosity
ρ_b	dry bulk soil particle density
τ	lag time
A	trench area
ABS	absorption factor
ABS_{GI}	absorption efficiency in the gastrointestinal tract
ACH	air changes per hour
ADAF	age dependent adjustment factor
AF	skin adherence factor
AST	aboveground storage tank
AT	averaging time
ATC	anticipated typical concentration
ATSDR	(federal) Agency for Toxic Substances and Disease Registry
AVS	acid volatile sulfides
B	dimensionless ratio of the permeability coefficient of a compound through the *stratum corneum* (outermost layer of skin, consisting of dead cells) relative to its permeability coefficient across the viable epidermis
BAF	bioaccumulation factor
BaPEq	benzo(a)pyrene equivalents
BERA	baseline ecological risk assessment
bgs	below ground surface
BTEX	benzene, toluene, ethylbenzene, and xylenes
BW	body weight
C_{air}	concentration of chemical in air
CAL/EPA	California Environmental Protection Agency
CDI	chronic daily intake
CERCLA	(federal) Comprehensive Environmental Response, Compensation, and Liability Act
CF	conversion factor
C_f	chemical concentration in food
C_{gw}	chemical concentration in groundwater
cm	centimeter

COC	chemical(s) of concern
COPC	chemical(s) of potential concern
cpm	counts per minute
C_s	chemical concentration in soil
CSF	cancer slope factor
CSM	conceptual site model
Css	chemical concentration in surface soil
CTE	central tendency exposure
CVOC	chlorinated volatile organic compound
D_a	apparent diffusivity
DAD	dermally absorbed chemical dose from water
DA_{event}	dermally absorbed dose per event
DAF	dilution attenuation factor
D_i	diffusivity in air
DoD	United States Department of Defense
DPT	direct push technology
DRO	diesel range organics
D_s	shower duration
D_t	total time in bathroom
D_w	diffusivity in water
dw	dry weight
EC	exposure concentration
ECD	electron capture detector
Eco SSLs	ecological soil screening levels
ED	exposure duration
EEQ	ecological effects quotient
EF	exposure frequency
Eh	redox potential
EM	electromagnetic
EPC	exposure point concentration
ERA	ecological risk assessment
ESA	environmental site assessment
EU	exposure unit
F	fraction of floor
FA	fraction absorbed
FAA	Federal Aviation Administration
FI	fraction ingested

FID	flame ionization detector
FOL	field operations leader
FS	feasibility study
gm	grams
GPR	ground penetrating radar
GPS	global positioning system
GRO	gasoline- range organics
GSL_{vapor}	groundwater screening levels for vapor intrusion
GSP	Greater Strawberry Point
H	Henry's Law constant
HASP	health and safety plan
HEAST	Health Effects Assessment Summary Tables
HHRA	human health risk assessment
HI	hazard index (indices)
HMW	high molecular weight
HQ	hazard quotient
IDW	investigation derived waste
If	food ingestion rate
ILCR	incremental lifetime cancer-risk
IR	ingestion rate
IRIS	Integrated Risk Information System
IR_w	groundwater ingestion rate
Is	soil ingestion rate
IUR	inhalation unit risk
°K	degrees Kelvin
K	mass transfer coefficient
KC	former Critical Test Building
K_d	soil water partition coefficient
kg	kilogram
kG,H2O	gas phase mass transfer coefficient of water vapor at 25°C
kg/day	kilogram(s) per day
K_i	contaminant's overall mass transfer coefficient
k_iG	gas phase mass transfer coefficient
k_iL	liquid phase mass transfer coefficient
kL,O2	liquid phase mass transfer coefficient of oxygen at 25°C
K_p	permeability coefficient of water through skin
KS	former Radioisotope Laboratory

LMW	low molecular weight
LOAEL	lowest observed adverse effect level
Lockheed Martin	Lockheed Martin Corporation
m	meter
MAA	Maryland Aviation Administration
MCL	maximum contaminant level
MDANG	Maryland Air National Guard
MDE	Maryland Department of the Environment
MDOT	Maryland Department of Transportation
µg/kg	microgram(s) per kilogram
µg/l	microgram(s) per liter
µV	microvolt
mg/kg	milligram(s) per kilogram
mg/kg-day	milligram(s) per kilogram per day
mg/L	milligram(s) per liter
MIP	membrane interface probe
mmho/m	millimho(s) per meter
MRC	Middle River Complex
MRL	minimal risk level
MSA	Martin State Airport
MSL	mean sea level
MTBE	methyl tert-butyl ether
MW	molecular weight
MW_i	molecular weight of component i (g/mole)
MWO_2	molecular weight of oxygen (g/mole)
n	total soil porosity
NAVD	North American Vertical Datum
NCEA	National Center for Environmental Assessment
NOAA	National Oceanic and Atmospheric Administration
NOAEL	no observed adverse effect level
NPDES	National Pollutant Discharge Elimination System
NRC	(federal) Nuclear Regulatory Commission
OPPTS	(USEPA) Office of Prevention, Pesticides, and Toxic Substances
ORNL	(United States Department of Energy) Oak Ridge National Laboratory
OSWER	(USEPA) Office of Solid Waste and Emergency Response
π	pi
PAH	polycyclic (or polynuclear) aromatic hydrocarbon

PCBs	polychlorinated biphenyls
PCE	tetrachloroethene
pCi/g	picocurie(s) per gram
PEF	particulate emission factor
pH	a measure of hydrogen ion concentration used to express the acidity or alkalinity of a solution
PID	photoionization detector
PPRTV	Provisional Peer Reviewed Toxicity Values
PVC	polyvinyl chloride
R	rejected data
Ra	air exchange rate
RAGS	*Risk Assessment Guide for Superfund*
RCRA	(federal) Resource Conservation and Recovery Act
REC	Recognized Environmental Conditions
RfC	reference concentration
RfD	reference dose
RME	reasonable maximum exposure
RSL	regional screening level
S	volatile chemical generation rate
SA	surface area
SDWA	(federal) Safe Drinking Water Act
SEM	simultaneously extracted metals
SERA	screening level ecological risk assessment
SP	Strawberry Point
SPCC	spill prevention, control, and countermeasures plan
SQGs	soil quality guidelines
SQL	sample quantitation limit
SSL	soil screening level
SSL_{sair}	soil screening level for chemical migration from soil to air
SSSL	surface soil screening level
SVOC	semivolatile organic compound
SwSL	surface water screening level
t*	time to reach steady state
TCE	trichloroethene
TCLP	Toxicity Characteristic Leaching Procedure
TEF	toxicity equivalency factor
Tetra Tech	Tetra Tech, Inc.

t_{event}	event duration
TIC	tentatively identified compound
TOC	Top of casing (polyvinyl chloride well casing)
TPH	total petroleum hydrocarbon
TRV	toxicity reference values
UCL	upper confidence limit
USEPA	United States Environmental Protection Agency
UST	underground storage tank
UXO	unexploded ordnance
V	trench volume
VDEQ	Virginia Department of Environmental Quality
VF	volatilization factor
VOC	volatile organic compound

Section 1
Introduction

On behalf of Lockheed Martin Corporation (Lockheed Martin), Tetra Tech, Inc. (Tetra Tech) has prepared this additional Phase II site investigation report for the Greater Strawberry Point (GSP) portion of the former Glenn L. Martin Airport (now known as Martin State Airport [MSA]) in Baltimore County, Maryland. The investigations described herein supplement the Phase II investigations at Greater Strawberry Point in October 2010. The Greater Strawberry Point study area is comprised of approximately 75 acres and is defined as the area extending from the southern end of the peninsula to the northern end, bordering Taxiway J, and eastward from Stansbury Creek to Taxiway F. Figure 1-1 depicts the location of Greater Strawberry Point.

The objective of this investigation is to better evaluate, via surface and subsurface explorations and testing, whether hazardous materials may have been placed or spilled (i.e., released to the environment) in the northern area of Greater Strawberry Point. The investigations sought to further characterize those areas of soil and groundwater impacts initially identified during the first round of the Phase II site investigation in October 2010. Current and potential human health and ecological risks posed by site conditions were assessed to quantify risks to human receptors and the ecological effects resulting from exposure to chemicals detected in the environment at Greater Strawberry Point.

Specifically, this investigation aims to provide additional environmental data for four Recognized Environmental Conditions (RECs) in two general areas of the Greater Strawberry Point study area to evaluate if hazardous materials may have historically been released as a result of Lockheed Martin predecessor firms' (i.e., Glenn L. Martin Co. and Martin Marietta Corporation) operations, or the operations of others. These two general areas of the Greater Strawberry Point study area are as follows:

- the clearing between the wooded area and Taxiway F, which includes Recognized Environmental Conditions #8, #9, and #10 (approximately 16 acres)

- the Northern Area (approximately two acres), which includes Recognized Environmental Condition #11 (the former Material Storage, former Critical Test Building [KC[1]]), and former Radioisotope Lab (KJ) buildings

Locations of the Recognized Environmental Conditions are shown in Figure 1-2. The four Recognized Environmental Conditions investigated as part of this study include:

REC* number	REC name
REC #8	Former Induction Test, former Engine Test, former Propulsion Test, and former Compressor Shed buildings
REC #9	Former Propellant Storage, former Acetylene Storage Shed, and former Furnace Building
REC #10	Former Coupon Test Shed and former Block House
REC #11	Former Critical Test Building (KC), former Radioisotope Lab (KJ), and former Transformer Pad

* REC: Recognized Environmental Condition

The following task-specific field activities were implemented to achieve the study objective:

- obtained an access agreement and associated permits for intrusive investigations from Lockheed Martin Corporation, Maryland State Airport, the Maryland Aviation Administration (MAA), and the Federal Aviation Administration (FAA) to conduct the planned field activities

- advanced 40 soil borings, consisting of 10 soil borings in the area of Recognized Environmental Condition #9, 10 soil borings in Recognized Environmental Condition #10, and 20 soil borings in Recognized Environmental Condition #11, along with collecting soil samples for laboratory analysis

- excavated 12 test pits in Recognized Environmental Conditions #9 and #10 that assessed buried materials/debris at geophysical anomalies identified by the previous geophysical survey in 2010

[1] *Buildings are generally designated using two letters or combinations of letters and numbers. The first letter is based on major operational areas such as the airport or Strawberry Point. For example, the first letter for peripheral airport buildings such as the former Radioisotope Lab is designated by a first letter "K." The second letter of a building designation is usually assigned alphabetically beginning with "A," but for some buildings the second letter is based on the first letter of the building name or use. The former Critical-Test Building is designated as "KC," where "K" represents the Nuclear Test and Oil Farm Area and "C" represents the first word (Critical) in the building name.*

- installed eight two-inch-diameter groundwater monitoring wells at three Recognized Environmental Conditions (#9 through #11) using a low-profile Mini-Sonic drill rig to a depth of approximately 32 feet below ground surface (bgs)

- collected and analyzed samples from the eight newly installed wells and eight existing temporary groundwater monitoring wells

- surveyed locations of new soil borings, test pit excavations, and monitoring wells using a Maryland-licensed surveyor

- collected, stored, and characterized investigation derived waste (IDW) and disposed of the waste at an off-site Lockheed Martin Corporation-approved treatment and disposal facility

- performed laboratory analysis and data validation

- evaluated environmental sampling data

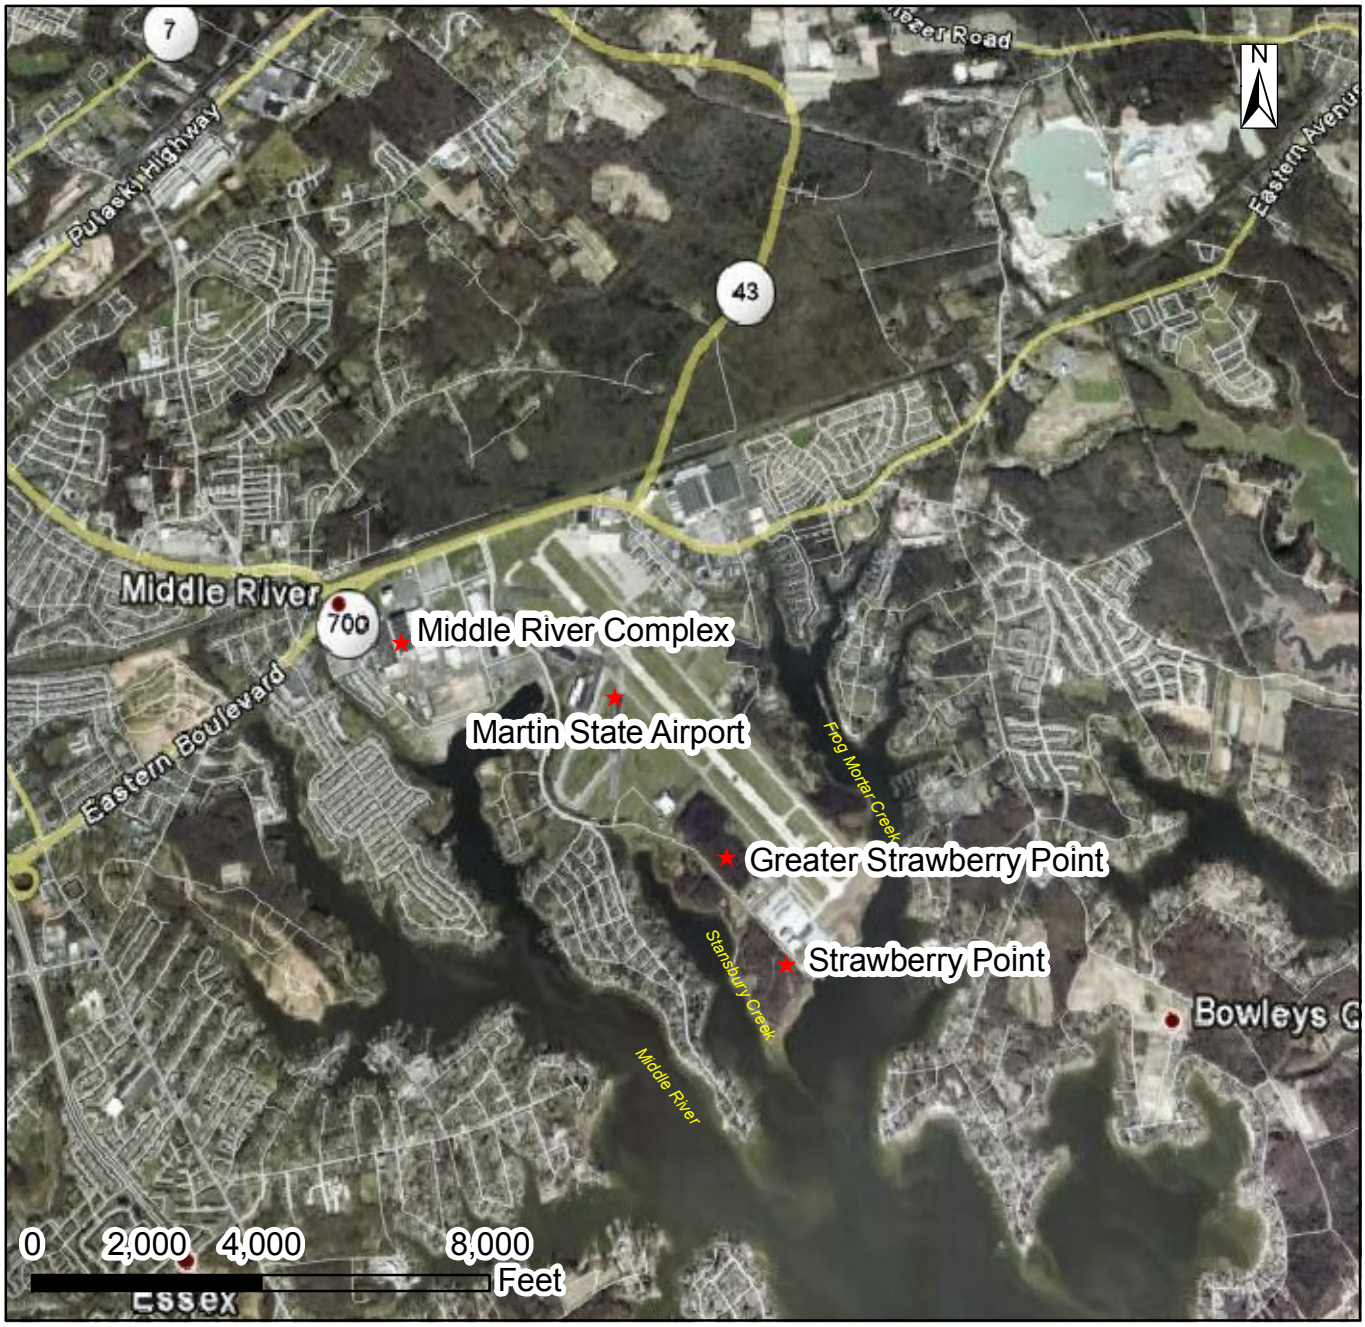
- completed human health and ecological risk assessments based on environmental sampling data from Recognized Environmental Conditions #9 through #11

This site investigation report is organized as follows:

Section 2—Site Background: Presents a brief overview of the site and its history and describes background conditions based on limited investigations. This section also describes the regional and site-specific subsurface geology and hydrogeology, based on the scientific literature and soil borings advanced at the site.

Section 3—Investigation Approach and Methodology: Presents the investigation's technical approach and describes the field methodologies used.

Section 4—Results: Presents the field program's investigation results.



Section 5—Human Health Risk Assessment: Compares the chemical results of the soil and groundwater samples against toxicological criteria using selected exposure scenarios to evaluate potential risk to human health.

Section 6—Ecological Risk Assessment: Compares the chemical results of the soil and groundwater samples against ecologic toxicological criteria to evaluate potential risk to ecological receptors.

Section 7—Summary: Summarizes the investigation findings.

Section 8—References: Cites references used to compile this report.

Section 2
Site Background

2.1 LOCATION AND HISTORY

2.1.1 Martin State Airport

Martin State Airport (MSA) is in eastern Baltimore County on the peninsula between Frog Mortar Creek and Stansbury Creek, both of which are tributaries of Middle River. Eastern Boulevard (Route 150) bounds MSA to the north; Lockheed Martin's Middle River Complex (MRC) borders MSA to the west. Figure 2-1 shows the location of MSA and surrounding properties. MSA is a regional airport for private and corporate use and includes a flight training school. MSA also serves as the airport for the Maryland Air National Guard (MDANG). MDANG occupies the northeastern corner of the airport property (see Figure 2-1).

The MDANG facilities were first occupied in 1955 by the 104th Tactical Fighting Group, later reorganized as the 175th Wing of the Air National Guard. In the 1960s and 1970s, the 135th Tactical Air Group was situated southwest of the MDANG facility at MSA and then relocated to the current MDANG facilities in October 1980. The MDANG facility currently leases 175 acres from the Maryland Aviation Administration (MAA) in the northeastern quadrant of the approximately 775-acre property owned by the Maryland Department of Transportation (MDOT), known today as MSA. The facility is fenced and has a separate entrance from Eastern Boulevard. The MDANG facility is developed, with runways, parking aprons, operations and training buildings, general supply and ammunition storage facilities, fuel storage structures, maintenance shops and sheds, and aircraft hangars.

The MSA Main Terminal facility (west of the MDANG facility and north of Greater Strawberry Point [GSP]) is at 701 Wilson Point Road, Middle River, Maryland. The current MSA property was part of the Glenn L. Martin Company's approximately 1,260-acre property, including surrounding areas containing manufacturing facilities. A search of Maryland land records and deeds indicates that the Glenn L. Martin Company purchased six parcels of land from private landowners during

the spring and summer of 1929, identified as 701 Wilson Point Road. During the 1940s and 1950s, nine additional parcels at this location were acquired from private landowners. In 1969, the Glenn L. Martin Company (then known as the Martin Marietta Corporation) transferred the properties to Chesapeake Park, Inc. (a subsidiary company of Martin Marietta Corporation), which then transferred the property to the State of Maryland in 1975.

Historical aerial photographs indicate that many of the original MSA main terminal facilities (three runways, Hangars 1–6, and the administration building) were constructed between 1939 and 1941. When the property was transferred to the State of Maryland in 1975, MAA assumed ownership and operation of MSA and the main terminal. Since then, MDANG has continued to lease the 175-acre portion of the 775-acre MSA property, and continued use of some of the taxiway and runway facilities on the main terminal property (see Figure 2-1).

2.1.2 Strawberry Point and Greater Strawberry Point Facility

Strawberry Point (SP) is within the confines of MSA, and is at the southern tip of the peninsula, at the confluence of Stansbury Creek and Frog Mortar Creek (see Figure 2-1). The previously investigated SP wooded area is at the south end of the peninsula and covers approximately 25 acres. The wooded area is bounded by earthen berms near the water line, with thick brush and trees covering most of the area.

Much of the SP wooded area was filled during the 1940s, reportedly by deposition of dredge spoils from Stansbury Creek and Frog Mortar Creek. A locked gate controls the entrance to the wooded area. The remainder of the area now under investigation, referred to as GSP, is a cleared and partially developed 75-acre area housing a former seaplane ramp, former delivery hangar, tank farm, police building, and maintenance buildings. It extends from the southern end of the peninsula to the northern end, which borders Taxiway J, and eastward from Stansbury Creek to Taxiway F. The airport runway is northeast of GSP.

The United States Navy leased GSP from the Glenn L. Martin Company from 1943 until 1963. At that time, the Navy used the facility and supporting structures, including a large hangar, for seaplane maintenance, launching, and recovery. During Navy occupancy, the former hangar and surrounding GSP area was known as the Naval Weapons Industrial Reserve Plant No. 148. The Air Force occupied the facility (Permit No. 1-N-MD-714) from 1963 until 1967.

During the United States Department of Defense (DoD) use (i.e., Navy and Air Force operations), the southern portion of the GSP near the wooded part of the site contained more than 10 buildings. These included the Beach House (Building 3), the Pumping Station (Building 4), the Chlorination Station (Building 5), two Power Fence Service Houses (Buildings 6 and 9), Solvent Storage (Building 7), the Equipment Storage Building (Building 8), Power Fence Switch House (Building 10), Delivery Hangar (Building ND/11), and a general storage building (Building 12). A tank farm containing aboveground storage tanks (ASTs) (used to store aircraft fuels) was adjacent to the wooded area near the southernmost tip of the developed area. Locations of current and historical MSA buildings are shown in Figure 2-2.

During the same period (1940s–1960s), the northern portion of GSP was developed with several improvements related to naval weapons research. These structures included the Induction Test Building (Building 13), Control House (Building 14), Noise Suppression Building (Building 15), Jet Test Shed (Building 16), Storage Building (Building 17), Propulsion Test Building (Building 22), Compressor Shed (Building 23), Engine Test Building (Building 24), and Vibration Slosh Test Building (near the current ground surface mounding). A missile testing area was once along a straight road northwest of the Propulsion Test building that included the Hyper-Therm Test facility (Building 25), Propellant Storage Shed (Building 18), Furnace building (Building 19), Acetylene Storage Shed (Building 20), Vanguard Tower (Building 21), Block House (Building 26), and three Coupon Test Sheds (Buildings 27, 28, and 29).

Several buildings dedicated to nuclear research and testing were constructed farther northwest, along a former dirt road connecting Strawberry Point Road to the historical airfield maintenance storage building (Building 37). Two main research buildings were designated as the Critical Test Building (Building 36/Building KC) and the Radioisotope Lab (Building 35/Building KJ). These research labs operated under federal Nuclear Regulatory Commission (NRC) permits. The buildings were decontaminated in the late 1980s and NRC terminated the licenses in 1995. A third building, known as the Liquid Metal Test facility (Building 34), was just south of the labs. Other buildings near the nuclear labs included several sheds (including an organic material storage shed) that were removed by Martin Marietta Corporation to allow for construction of Taxiway J.

Historical records indicate that two underground storage tanks (USTs) were installed during DoD's use of the southern GSP facilities. A 10,000-gallon heating oil UST was adjacent to the hangar (Building ND) to provide fuel to the hangar's heating system. This UST was closed in place in 1987 (post-DoD period) when the hangar's heating system was converted from fuel oil to natural gas. Both the lease and permit for the Air Force expired on November 30, 1967.

Eleven USTs have been removed from MSA since 1983, and no evidence of leakage has been reported. The large hangar (designated as Building ND) was demolished in 1989, and two adjacent hangars (currently housing the Maryland State Police) were constructed in 1989 and 1990. The southern portion of GSP is occupied by the Baltimore County Marine Police.

GSP currently contains a tank farm consisting of 12 ASTs containing jet fuel, fuel oil, and gasoline, along with a pump house and other ancillary buildings currently used by the airport. As many as six ASTs at the tank farm are used by other airport tenants. An oil spill was reported during construction of the new hangar in 1989 and 1990, when a fuel oil return and receiving line to two 12,000-gallon ASTs in the tank farm was severed. No additional information can be found on this spill in Maryland Department of the Environment (MDE) records (DERP-FUDS, 1991).

2.2 PHYSICAL FEATURES

2.2.1 Land Use

MSA is generally characterized as a moderately developed tract in a largely suburbanized, moderate density, populated setting. Land use surrounding MSA is a combination of mixed suburban, industrial, and commercial lightly to moderately developed tracts; some undeveloped woodland tracts are also present. MSA is bordered on the north by Eastern Boulevard (Maryland Route 150) and Amtrak railroad lines. Undeveloped woodland tracts and low-density residential properties are north of MSA and the Amtrak line. The eastern, southern, and western boundaries of MSA are bordered by Frog Mortar Creek and Stansbury Creek, which are wide, brackish, tidal tributaries of the Chesapeake Bay.

Lockheed Martin's MRC, which currently assembles military launch electronics and aircraft parts, is along MSA's northwestern boundary. Low-to-medium density residential land use and light commercial land use (i.e., shopping centers, convenience stores, restaurants, etc.) lie beyond the

creeks east, south, and west of MSA. Farther east and west from MSA are the high-density residential communities of Bengies Corner and Hawthorne Park.

2.2.2 Climate

The climate at MSA is characterized as humid temperate, with hot humid summers and relatively mild winters. The Middle River, Maryland area receives an average of 42 inches of precipitation annually. This amount is distributed evenly throughout the year. Rainfall normally occurs in the summer months in the form of showers and thunderstorms. In winter, precipitation is in the form of light to heavy rain or snow. Tropical storms in late summer and fall, and occluded, meso-scale, frontal systems (i.e., coastal low-pressure systems) in winter and spring, occasionally provide short term above average precipitation to the area.

2.2.3 Physiography

MSA is in the western shore of the Coastal Plain physiographic province. The Coastal Plain consists of sediments composed of alluvium from the Pleistocene Epoch and the Potomac Group from the Cretaceous Period. Coastal Plain sediments begin at the fall line and follow a regional dip to the southeast at approximately 110 feet per mile (Hansen and Edwards, 1986). The fall line is the division between the Piedmont and Atlantic Coastal physiographic provinces. The name refers to an imaginary line connecting waterfalls or changes in stream flow between the hard rock upland areas of the Piedmont and the soft sediment lowland areas of the Coastal Plain. The Coastal Plain is generally characterized by low topographic relief. However, steep embankments and hills are found along stream channels, rivers, and the Chesapeake Bay.

2.2.4 Topography

Most of the land surface at MSA is generally flat to gently sloping in the areas of the airport runway, taxiways, and surrounding support operations. The airport runway forms a northwest-southeast trending topographic ridge (or drainage divide) that slopes gently from the northwest end down to the southeast end. Runway elevations range from slightly over 20 feet above mean sea level (MSL) at the northern end of the runway to slightly over 10 feet above MSL at the southern end of the runway. The land also slopes northeastward and southwestward, away from the runway, toward Frog Mortar Creek and Stansbury Creek.

GSP is southwest and south of the runway. Site topography ranges from flat to gently sloping to the southwest, toward Stansbury Creek. In the northern portion of GSP, land elevations range from approximately 11 feet above MSL near the runway to nearly mean sea level along the Stansbury Creek shoreline. In the southern wooded area of SP, land elevations are approximately eight- to nine-feet above MSL. At the southern wooded area, an embankment slopes steeply along the western shoreline of Frog Mortar Creek and along the eastern shoreline of Stansbury Creek. The top of the Frog Mortar Creek embankment is slightly over 20 feet above MSL; the top of the Stansbury Creek embankment is approximately eight feet above MSL.

2.2.5 Surface Water Hydrology

MSA's eastern, southern, and western boundaries are bordered by Frog Mortar Creek and Stansbury Creek, which are wide, brackish, tidal tributaries of the middle Chesapeake Bay. Surface water runoff from MSA enters these creeks via localized gullies in the eastern and western undeveloped portions, or by storm sewers that drain the airport runway, taxiways, and developed portions of the facility. MSA encompasses 47 drainage areas within three watersheds (Frog Mortar Creek, Stansbury Creek, and Dark Head Cove) to form a total drainage area of approximately 700 acres. The airport drainage areas range in size from seven acres to more than 170 acres. A variety of owner occupied and commercial tenant hangars and buildings are within several drainage areas.

Surface drainage from GSP discharges via multiple outfalls to Stansbury Creek and Frog Mortar Creek. Stansbury Creek receives drainage from Outfalls 07, 12, and 06, and Frog Mortar Creek receives drainage from Outfalls 05 and 03. Outfalls are shown in Figure 2-2. Outfall 07 has a drainage area of 30 acres and receives drainage from runway access, parking, commercial tenant buildings, private tenant hangars, and a wetland mitigation site. The drainage area also includes grassy surfaces along Wilson Point Road and Strawberry Point Road. Impervious areas include aircraft and vehicle parking areas. The airport's wetland mitigation site and bordering vegetated areas cover this drainage area. Outfall 07 is at the exit of an existing 24-inch storm drain system.

Outfall 12 receives drainage from about 172 acres of pervious and impervious areas, including fueling areas, parking, vehicle/equipment maintenance, vehicle washing area, de-icing operations, chemical storage, the runway and taxiways, taxi lanes, runway access, airport rescue and firefighting, MDANG facilities/buildings, commercial tenant buildings, private tenant

hangars, and two storm water management water quality basins. The two storm water management water quality basins collect drainage from the watershed drainage areas and outfalls into Stansbury Creek. The water is conveyed via Outfall 12 at the exit of the 4.5-foot by 4.5-foot box culvert downstream of the water quality basin.

Outfall 06 receives drainage from about 85 acres of pervious and impervious areas, including vehicle/equipment maintenance, de-icing operations, chemical waste storage, taxiway and runway access, parking, maintenance and auto shop, private tenant hangars, and storage piles of soil, asphalt millings, and stone. The area includes grassy surfaces along Strawberry Point Road and between parking areas, and dense tree zones. Impervious areas include portions of the Strawberry Point Road, Taxiway S, and aircraft and vehicle parking areas. Other areas include airport maintenance service, storage buildings, private hangars, and a fuel farm. Monitoring for Outfall 06 is at the exit of an existing storm drain system discharging into Stansbury Creek.

Outfall 05 receives drainage from about 18 acres of pervious and impervious areas, including fueling, painting, vehicle/equipment maintenance, vehicle/equipment washing, de-icing operations, material loading, industrial waste management, emergency firefighting, police, maintenance and storage, marine rescue, fuel farms, and the helicopter landing site. The area also includes grassy surfaces adjacent to parking areas, dense tree zones, aircraft and vehicle parking areas, and runway access. Monitoring for Outfall 05 is at the entrance to a grass lined swale discharging into Frog Mortar Creek. Outfall 03 receives drainage from pervious and impervious areas, including grassy surfaces adjacent to runway access, runways, and taxiways covering 61 acres. Monitoring for Outfall 03 is at the entrance to the exit of an existing 54-inch storm drain discharging into Frog Mortar Creek.

These facility outfalls are monitored monthly to ensure that no oily discharges to surface water occur. Secondary containment drains are also routinely inspected and emptied of storm water. All storm water runoff originating from Martin State Airport discharges to outfall areas, as specified in the facility's General National Pollutant Discharge Elimination System (NPDES) permit (No. MDR 05501), General Discharge permit (No. 05-SF-5501). The permit has an effective date of November 12, 2004 and expiration date of November 12, 2009. However, MDE has administratively extended the permit until they issue a new general permit, so the current permit remains in effect.

The site's general industrial permit has no monitoring requirements. However, limited monitoring is performed as part of the Municipal Separate Storm Sewer System permit required for the Illicit Discharge Detection and Elimination program. This limited monitoring includes laboratory analysis for ammonia, dissolved oxygen, surfactants, fecal coliform, potassium, water temperature, conductivity, pH, and fluoride concentrations in monitored outfalls during annual inspections. Visual inspections are routinely performed and annual reports are submitted to MDE.

2.2.6 Regional Geologic and Hydrogeologic Conditions

MSA is in the western shore of the Coastal Plain physiographic province. Regional and local studies (Vroblesky and Fleck, 1991; Chapelle, 1985) indicate that the facility lies on the Patapsco Formation, which consists of complex and interbedded mixtures of gray, brown, and red sands, silts, and clays originating from sediment deposited in a low coastal plain traversed by low gradient meandering streams. Below the Patapsco Formation is a regionally extensive, thick clay confining unit known as the Arundel Formation. It is a massive and probably impermeable unit underlying MSA and surrounding area.

The Arundel Formation outcrops northwest of MSA and dips and thickens to the southeast. It extends as far east as Cambridge, Maryland, where it is more than 600 feet thick. In 2010, four deep soil borings were advanced to depths ranging from 216–316 feet below grade at the MRC. A series of alternating sand and silt aquifers and clay aquitards lies beneath the lower surficial aquifer. Beneath these alternating layers, 73 feet of contiguous clay were encountered in the northern portion of the MRC, starting at an elevation of 164 feet below MSL (189 feet below grade) and ending at an elevation of approximately 237 feet below MSL (262 feet below grade). The top surface of this clay was also encountered at elevations of approximately 174 and 183 feet below MSL in the central and southern portions of the MRC. This thick clay is considered the main portion of the Arundel Formation.

The Patuxent Formation is found below the Arundel Formation. The Patuxent Formation is a multiaquifer unit, as evidenced by various interbedded sand and silt/clay layers and the rapid changes in deposited material types over short distances. Permeable, sand rich units range from bounded sand sheets to isolated sand bodies (Glaser, 1969). In the MSA area, potentiometric

maps of the Patuxent Formation indicate that groundwater flows to the south and southwest in response to industrial wells withdrawing water southwest and west of the site (Chapelle, 1985).

2.2.7 Vicinity Subsurface Conditions

An extensive, ongoing, subsurface investigation has been conducted at MSA's Dump Road site, which is east of the GSP area and adjacent to Frog Mortar Creek. As part of the Dump Road investigation, numerous shallow and deep soil borings were advanced to collect soil samples for subsurface lithologic information. Synoptic water levels, single-well permeability tests, and pumping tests were conducted to characterize subsurface hydraulic conditions at MSA.

Early studies at the Dump Road site indicate that the subsurface hydrogeology is comprised of a surficial aquifer (i.e., the Patapsco Formation) containing highly heterogeneous mixtures of unconsolidated sand, silt, gravel/sand mixtures, and clay. A layer of fill, consisting of heterogeneous sand, silt, and clay, overlies these native sediments. For data evaluation and correlation, the surficial aquifer was divided into the upper, intermediate, and lower surficial aquifer zones. The lower surficial aquifer zone is encountered up to approximately 45–73 feet below MSL and overlies at least several feet of stiff, dense clay.

A 2008 study investigated the lithology beneath the lower surficial aquifer in the Dump Road area of MSA. Lithologic data from four deep wells indicate six to 40 feet of clay beneath the lower surficial aquifer. Deep well logs also indicate alternating sand and silt aquifers and clay aquitards beneath the lower surficial aquifer. These sandy units are referred to as the deep confined aquifer zones.

2.2.7.1 Surficial Aquifer

At the Dump Road area of MSA, all but four wells are screened in the surficial aquifer system, but at different elevations, to provide hydrologic and chemical data across the entire water bearing zone. Excluding several abandoned small diameter wells (i.e., abandoned wells TT-12, TT-13 and TT-14) and the new wells installed during the current GSP Phase II follow-on work, 35 groundwater monitoring wells are screened in the upper surficial aquifer, which is the portion from the ground surface to an elevation of approximately 15 feet below MSL. Generally, the upper surficial aquifer consists of fill that occurs in the uppermost 10–20 feet below grade, and native soils beneath the fill materials. Thirty-two wells are screened in the intermediate surficial

aquifer, which is the portion of the aquifer system at elevations between 15–45 feet below MSL. Twenty wells are screened in the lower surficial aquifer, which occurs at elevations from approximately 45–73 feet below MSL.

2.2.7.2 Deep Confined Aquifers

Four wells at MSA are screened in deep confined aquifers underlying the lower surficial aquifer. The deep well logs indicate that alternating sand and silt aquifers and clay aquitards lie beneath the lower surficial aquifer. Lithologic data from the four deep wells indicate six to 40 feet of clay beneath the lower surficial aquifer. Beneath this clay bed is a series of alternating sand and clay layers with top surfaces occurring at approximate elevations of 120–130 feet below MSL (sand), 140–160 feet below MSL (clay), 190 feet below MSL (sand), 197–205 feet below MSL (clay), and 245 feet below MSL (sand).

2.2.7.3 Groundwater Levels

Static groundwater levels measured in wells in the Dump Road area of MSA are reported at depths ranging from five to 18 feet below grade in the upper surficial aquifer wells, three to 18 feet in the intermediate surficial aquifer wells, and four to 18 feet in the lower surficial aquifer wells. Shallow groundwater is encountered in the recharge areas of the western portion of Dump Road near the runway. Deeper groundwater is found in the high topographic areas at the top of the embankment along the shoreline (i.e., wells DMW2, DMW4, DMW5, etc.).

Groundwater in the surficial aquifer generally follows surface topography. At the Dump Road Area, groundwater flows northeast from the airport runway and taxiway toward Frog Mortar Creek. Groundwater in the intermediate surficial aquifer also flows northeast from the runway and taxiway toward Frog Mortar Creek. Groundwater flows south in the southern portion of the Dump Road site.

Groundwater potentiometric levels in the lower surficial aquifer are similar to those of the intermediate surficial aquifer. Both the intermediate and lower surficial aquifers have northern components of flow in the northern portion of the site and southern groundwater flow in the southern portion of the site. Groundwater flows from the northwest to the southeast in the deep confined aquifer.

2.3 SUMMARY OF PREVIOUS INVESTIGATIONS

Studies to date include Phase I environmental site assessment (ESA) activities and Phase II intrusive investigations. The Phase I ESA and historical records review address both the wooded area (Recognized Environmental Condition [REC] #1) of SP, and the remaining 75 acre GSP facility. Various levels of assessment were completed during Phase II, including one investigation that addressed only the wooded area, and a broadened Phase II investigation in 2010 covering the entire GSP area. Details of these studies are summarized below.

2.3.1 Strawberry Point Phase I Investigations

A Phase I ESA of the SP facility was conducted in the winter of 2007–2008 to evaluate historical site activities pertaining to the wooded area, tank farm, former hangar area (Building ND), facility maintenance yard, and nuclear research buildings (Tetra Tech, Inc. [Tetra Tech], 2009b). The investigation reviewed historical facility documents, drawings, photographs, aerial photographs, and government records (NRC, USEPA, MDE, and Baltimore County) of appropriate permits and any violations. These investigations also included interviews with former and current employees, a visual site inspection, and geophysical investigations of the wooded area. The subsurface geophysical survey in September 2008 included electromagnetic (EM) and surface gamma surveys.

The *Phase I ESA* presents the following conclusions:

- Review of historical aerial photographs from 1938 to the present identified evidence of ground disturbances throughout SP, including additional dredging and filling, to prevent shoreline erosion, and/or increase usable land space. Shoreline changes are evident on all sides of SP, with smoothing of the edges from dredge spoil fillings.

- Tetra Tech identified 11 RECs in the GSP area, including the wooded area, based on the historical investigation. Some operations were combined as RECs if they were in close proximity.

- Of the listed RECs, additional investigation of REC #1 (SP-Wooded Area) was recommended to characterize the subsurface soils and groundwater quality. Historical information suggests that dredge spoils may have been deposited in the wooded area.

- Two buildings dedicated to nuclear research and testing during the 1950s and 1960s were decontaminated in the late 1980s. NRC terminated the licenses for these facilities in 1995. These buildings were later demolished.

- Violations in the handling of hazardous and non-hazardous substances at SP have been reported. Most significantly, approximately 200 55-gallon drums containing hazardous and non-hazardous materials were stored at the facility maintenance yard area. They were removed after a state inspection in 1989.

- Minor spills of petroleum constituents resulting from overfills and line ruptures related to site ASTs have been reported.

- Most of the historical structures that existed in the 1960s have been demolished. Several older buildings remain but are dilapidated.

2.3.2 2008 Phase II Investigations at REC #1

The following Phase II field activities were completed during August–September 2008 in the SP area of MSA. The investigation included excavating 20 test pits to 10 feet below grade. Twenty soil samples were collected for chemical analysis of volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), metals, and polychlorinated biphenyls (PCBs). Of these 20 samples, five were also analyzed for radionuclides.

Eleven soil borings were advanced via direct push technology (DPT) to 15 feet below surface. Soil samples were collected and analyzed for VOCs, SVOCs, metals, and PCBs. Five temporary well points were installed in DPT soil borings, and groundwater samples were collected and analyzed for VOCs, SVOCs, metals, and PCBs. Additional tasks included well gauging, surveying soil borings, test pits, and well points, and waste characterization and disposal at a Lockheed Martin-approved waste disposal facility.

Here is a summary of these activities:

- Soil borings indicate that the top 10 feet of soil at the site is comprised of varying amounts of sand, silt, and clay, underlain by fine-to-medium sand from a depth of 10 to approximately 16 feet.

- The water table at the site was observed to be between 2.83 and 3.86 feet below grade.

- Groundwater elevations indicate that groundwater beneath SP flows in a southwestern direction toward Stansbury Creek.

- No evidence of contaminated fill material was found during excavation of the test pits. No visual discolorations were encountered in test pit and soil boring soils.

- Test pit soil sample analyses indicate low levels of two VOCs: 2-butanone and acetone. Detection of both of these VOCs may be due to laboratory contaminants.

- Low levels of SVOCs, including polycyclic aromatic hydrocarbons (PAHs), were detected in test pit soils.

- Metals were found throughout the 20 test pits. Detected concentrations of aluminum, arsenic, total chromium, iron, manganese, and vanadium exceed MDE residential soil criteria. In general, metals concentrations appear consistent with local background concentrations in soil and do not indicate a release at the SP wooded site.

- Five test pit soil samples were analyzed to confirm gamma anomalies. Gross alpha (maximum concentration of 24.5 picocuries/gram [pCi/g]) and gross beta (maximum concentration of 28.5 pCi/g) were detected in all five samples. Radionuclide concentrations were distributed evenly across the site, and all concentrations are similar.

- Geophysical investigations revealed conductivity, in-phase, and natural gamma anomalies at the SP wooded area.

- The EM in-phase data show one linear anomaly, possibly an abandoned utility.

- The survey delineated three areas with coincident elevated in-phase readings and terrain conductivity readings.

- Five areas of terrain conductivity only anomalies were identified on the southern end of the survey area.

- The surface gamma survey results show two areas of above background, gross count gamma readings.

- Metals were found throughout the 11 soil boring locations. Concentrations of aluminum, arsenic, total chromium, iron, manganese, and vanadium exceed MDE residential soil standards. In general, metal concentrations in soil appear consistent with local background concentrations and do not indicate a release at the SP wooded site.

- Several PAHs were detected in the groundwater sample from an upgradient well point (WP2/SB 2). PAHs were detected at low concentrations (0.55–2.9 micrograms per liter [µg/L]); nevertheless, some detected concentrations exceed MDE groundwater standards.

- Metals were detected in groundwater samples from all well points. Specifically, aluminum, arsenic, beryllium, cadmium, iron, manganese, nickel, vanadium, and zinc concentrations exceed MDE groundwater criteria for both total and dissolved metals. In general, concentrations of these metals increase in the downgradient direction, consistent with decreasing pH and dissolved-oxygen concentrations in groundwater. These data suggest that metals may be moving into the dissolved phase due to these geochemical conditions. The wooded area has generally low pH levels, exhibiting more acidic soil conditions compared to upgradient open areas. Elevated concentrations of aluminum, iron, and manganese in well points correspond to those found in a commonly low-pH environment containing acidic soils in shady, moist, peat soils.

2.3.3 2010 Phase II Site Investigation

A second Phase II environmental investigation was conducted in April and May 2010 at the GSP area of MSA to determine the nature and extent of environmental impacts in soil and groundwater at 10 RECs (RECs #2 through #11) in three main areas of GSP. The study identified specific chemical constituents and their concentrations in soil and groundwater, using field screening techniques and fixed laboratory analyses to provide definitive chemical data. The chemical analytical results were screened against State of Maryland human health soil and groundwater standards to assess the need for additional sampling, or to support no further action. The following field investigations were completed:

- EM geophysical surveys were conducted across the approximately 10 acres of RECs #7-#10 to detect and delineate possible subsurface metallic objects and buried building remnants. Site history suggests that items that could possibly be found in the survey area could include demolition debris from razed buildings, abandoned in place USTs, buried drums, abandoned utilities, active utilities, and remnants of concrete pads.

- Soil and groundwater were screened using membrane interface probes (MIPs) at 20 locations to a maximum depth of 43 feet below grade at RECs #2 through #4 to help locate and delineate possible areas of subsurface impacts. Horizontal and vertical coordinates were surveyed for the MIP borings.

- Soil borings were advanced to a depth of 25-feet at 89 locations. Soils were collected for soil lithologic information and screened in the field for VOCs using a portable photoionization detector (PID). Soil samples were collected and sent to a fixed laboratory for chemical analyses for VOCs, SVOCs, PCBs, metals, total petroleum hydrocarbon (TPH) diesel-range organics (DRO), and TPH gasoline-range organics (GRO).

- DPT-probe groundwater samples were collected at seven locations and submitted to a fixed laboratory for chemical analyses for VOCs, SVOCs, PCBs, metals, TPH-DRO and TPH-GRO.

- Temporary wells were installed at 16 DPT soil boring locations. Groundwater samples were collected from these 16 temporary wells and submitted to a fixed laboratory for chemical analyses for VOCs, SVOCs, PCBs, total and dissolved metals, TPH-DRO, and TPH-GRO.

- Static groundwater levels were measured at the 16 newly installed temporary wells over two events in June and August 2010. These levels were used to develop groundwater elevation contour maps for both events.

- Horizontal and vertical coordinates were surveyed for the MIP borings.

Here is a summary of the results of the initial Phase II field investigation:

- The lithology encountered in the soil borings varies across the RECs. On the eastern side of REC #2, the top 10 feet consists of clayey silt and clay with fine sandy silt from depths of 10-5 feet. From the central portion of REC #2 to REC #6, the subsurface lithology consists of gray and brown clay and silty clay to a depth of 25 feet, with occasional thin, silty-sand, and sandy-silt layers/lenses. In the REC #7 area, gray and brown silty-sand and sandy silt with occasional clay lenses are encountered to a depth of 25 feet. The subsurface lithology at RECs #8 and #9 is similar to REC #7, except for a thick clay layer from approximately 14–22 feet below grade. This clay layer thickens somewhat at REC #10 to the west. The REC #11 subsurface lithology varies somewhat and ranges from an area in the north comprised of nearly all silty clay to a depth of 25 feet, to an area in the center of REC #11 consisting of 12 feet of silty sand and sandy silt overlying 13 feet of clay, to an area in the south comprised mostly of sandy silt and few clay layers.

- The water table at the site ranges from just below the ground surface to nearly eight feet below grade. Shallower groundwater levels tend to be found along the eastern portion of GSP in areas of higher ground elevations (9–11 feet MSL) and where near surface sandy or gravelly materials overlie shallow clay (e.g., SB/WP66, SB/WP-44, SB/WP-13, SB/WP-33, SB/WP-39, and SB/WP-40). The deepest groundwater levels were found at wells to the west (SB/WP-54, SB/WP-61, and SB/WP-71) and south (SB/WP-02).

- Groundwater elevations indicate that groundwater beneath the GSP generally flows in a southerly direction toward Stansbury Creek and Frog Mortar Creek. Groundwater mounding at REC #7 appears to create localized radial flow.

- MIP screening indicates the possible limited presence of chlorinated VOCs in soil at RECs #2–#4. MIP screening results do not indicate petroleum related VOCs.

- Trace to low concentrations of VOCs were detected in soil samples collected at all RECs. However, these levels are less than Maryland residential and non-residential soil standards, and many appear to be artifacts of the laboratory analyses. Trichloroethene (TCE), a chlorinated solvent detected at the Dump Road Area of MSA, was detected at low concentrations in shallow soil samples at REC #4 and in deep soil samples at RECs #9 and #11. TCE was detected at concentrations up to a maximum of 1,100 micrograms per kilogram (µg/kg) in a soil sample from the 20–22 feet depth at REC #9.

- SVOCs were detected in soil at several RECs. However, most SVOC concentrations are less than residential and non-residential standards. SVOC concentrations slightly exceed residential standards at several RECs, and exceed non-residential standards at RECs #9 and #11. The highest concentrations of SVOCs, and greatest number of non-residential exceedances, are associated with samples from RECs #9 and #11. However, these exceedances are limited to surface and shallow soils from a maximum depth of seven feet below grade.

- PCB concentrations ranging from 3,100–12,000 µg/kg in three shallow soil samples at REC #11 exceed Maryland residential and non-residential soil standards of 320 and 1,400 µg/kg (respectively). A fourth shallow sample at REC #11, with a PCB concentration of 1,200 µg/kg, exceeds the residential standard only.

- Concentrations of arsenic, total chromium, iron, manganese, nickel, and vanadium in soil exceed standards at most sites. Iron and manganese concentrations vary greatly, and elevated concentrations of these constituents may be due to metals in soil fill materials, former buildings, or other ground structures. Arsenic and vanadium frequently exceed their risk-based standards. However, in general, concentrations of these two metals are similar to MDE's anticipated typical concentrations (ATCs), or "regional background" concentrations, for the eastern region of Maryland. Therefore, concentrations of these metals appear consistent with local background and not indicative of a release at GSP.

- Concentrations of arsenic, beryllium, iron, manganese, nickel, and vanadium exceed groundwater standards in one or more groundwater samples. Several exceedances appeared to be the result of high turbidity in probe groundwater samples or temporary well samples. VOCs and SVOCs detected in groundwater samples did not exceed standards, and the chemicals detected are typically common laboratory contaminants and artifacts of laboratory analyses.

2.4 CURRENT SITE CONDITIONS AND OPERATIONS

Currently, GSP includes the SP wooded area, an airport maintenance area, hangars, a fuel storage tank farm, the southern terminus of the MSA runways, and associated aprons. GSP is part of the larger MSA property owned by MDOT. The Maryland State Police lease the large hangar near the SP wooded area and use it for light aircraft and helicopters. This hangar was constructed in the early 1990s near the former Delivery Hangar (Building No. 11) that was demolished in 1989. Farther south, a small building (Building No. 003) near Frog Mortar Creek is occupied by the Baltimore County Marine Police.

The MSA maintenance area is approximately 700 feet northwest of the Police Hangar. Buildings currently in use in the maintenance area include a salt dome (Building No. 049), a sand dome (Building No. 050), and a maintenance building (Building No. 022). These structures were built in the early 1990s. Immediately north of GSP is the new Lockheed Martin hangar (Building No. 051) and the Black and Decker hangar (Building No. 052). These buildings were constructed near the former nuclear research labs in the late 1990s. Refer to Figure 2-2 for their locations.

The MSA fuel storage tank farm is on the southern edge of the airport, close to Frog Mortar Creek. Thirteen MAA ASTs, with a total capacity of nearly 95,000 gallons, store Jet A fuel, aviation gasoline, unleaded gasoline, diesel fuel, and waste oil. Secondary containment at the tank farm consists of concrete containment dikes with ancillary oil and water separators that discharge into a nearby drainage ditch (NPDES monitoring Outfall 005), which flows into Frog

Mortar Creek. The oil and water separators remove petroleum from storm water runoff conveyed through the drainage systems from various impervious areas of the airport, and are maintained via periodic inspections and cleaning.

The tank farm is divided into east and west sides. The east side is further divided into the north and south containment areas. Tanks MAA 1 through MAA 3 are in the north containment area; each stores 12,000-gallons of Jet A fuel or aviation gasoline. Tanks MAA 4 through MAA 6 are in the south containment area, each with a capacity of 12,000 gallons (MAA, 2008). Details of the MSA tanks are in the *Spill Prevention, Control, and Countermeasures Plan* (SPCC). Figure 2-2 shows the location of the fuel-storage tank farm.

Tanks in this area are used by both MAA and the Maryland State Police. Buried pipes from the containment areas deliver fuel to the Maryland State Police fuel rack. The fuel tanks are filled under contract with Exxon Mobil. Tank trucks are filled at these containment areas; these trucks transport fuel to airplanes throughout the airport.

The southern portion of the eastern portion of the tank farm contains two 6,000-gallon unleaded gasoline tanks (MAA 7 and MAA 8) and one 6,000-gallon diesel fuel tank (MAA 9) owned by MAA. These tanks provide fuel for state-owned vehicles, including the tank trucks. A 4,000-gallon AST (MAA 21) stores aviation gasoline. The tank farm has two waste oil tanks (MAA 22 and MAA 23) in two different containment areas: the first is a 275-gallon AST in the containment dike with ASTs MAA 4 through MAA 6; the second is a 350-gallon AST in the containment dike with ASTs MAA 7 through MAA 9. An additional 275-gallon tank (MAA 26), in the containment dike with ASTs MAA 1 through MAA 3, captures vapor from the pressure release valve on filter vessels; used fuel does not enter this tank.

Several tenant owned ASTs are also at the tank farm: two 30,000-gallon and two 12,000-gallon Jet A fuel tanks, one 500-gallon waste oil tank, and two 275-gallon waste oil tanks. All tanks in the tank farm are within secondary containment dikes. An additional six fixed storage containers are throughout the facility: three 500-gallon diesel fuel tanks (MAA 18 through MAA 20) inside the Fire Pump House; an out of service 500-gallon tank near the Maintenance Shop; and an out of service 55-gallon drum inside the storage shed. Site records indicate that, except for the unused ASTs, all of these tanks have adequate secondary containment.

Drums are routinely stored at the airport in designated storage areas. Two such areas are in the Maintenance and Auto Shop (MAA 15 and MAA 16); a third is inside the Maintenance Shed southeast of the Maintenance and Auto Shop (MAA 17). Unopened stocks of motor oil, transmission fluid, and hydraulic fluid are stored in the area designated MAA 17; stock currently in use is stored in the area designated MAA 15. Small drums of waste oil are stored in the area designated MAA 16. All other drum storage areas typically store no more than five drums, although the number of drums stored in each area may vary depending on operational needs. All drum storage areas have secondary containment pallets on which the drums are stored. The results of the first round (October 2010) of the Phase II site investigation and current site conditions led to the additional Phase II investigation described herein (see Section 3) to further characterize soil and groundwater conditions at the GSP study area.

Section 3
Investigation Approach and Methodology

The findings of the 2010 Phase II site investigations led to recommendations that soil and groundwater be further characterized to better evaluate whether hazardous materials (if present) may have been placed or spilled (i.e., released to the environment) in the northern area of Greater Strawberry Point (GSP) as a result of previous Lockheed Martin Corporation (Lockheed Martin) operations at the site. Today this area is largely wooded; historically, it was the site of multiple facilities that have since been demolished. The area characterized during this GSP Phase II investigation is approximately 12 acres and includes:

- a clearing between the wooded area and Taxiway F
- the Jet Test Shed
- former propellant and acetylene storage sheds
- a compressor shed
- a former coupon test shed
- a former Noise Suppression Building
- a storage building
- engine test and current maintenance sheds
- a former furnace building
- a former block house

This area had been previously defined as Recognized Environmental Conditions (RECs) #8 through REC #10. Additional areas to be characterized include the former maintenance storage, critical test and radioisotope buildings, and the former transformer pad, comprising approximately 2.5 acres immediately south of Taxiway J (REC #11).

The additional Phase II study included soil borings, test pit excavations, and installation and sampling of groundwater monitoring wells to evaluate and characterize the subsurface for the presence of hazardous materials in soil and groundwater at RECs #8 through #11. The following site activities were conducted as part of this Phase II investigation:

- obtained site access and utility clearance
- obtained Lockheed Martin, Maryland State Airport (MSA), and Maryland Aviation Administration (MAA) permits for intrusive investigations
- coordinated with MAA, Maryland State Police, and other MSA tenants to schedule work
- excavated test pits and collected soil samples for chemical analyses
- advanced soil borings using direct push technology (DPT) and collected soil samples for chemical analyses
- installed temporary well points in drilled soil boring locations and collected groundwater samples for chemical analyses
- installed, developed, and sampled new groundwater monitoring wells for chemical analyses
- surveyed locations of test pits, DPT soil borings, and monitoring wells
- collected, managed, and disposed of investigation derived waste (IDW)
- performed laboratory analyses and data validation
- evaluated environmental sampling data
- completed human health and ecological risk assessments using environmental sampling data from RECs #9 through #11[2]

The investigation began with the test pit exploration and sampling, followed by the installation and sampling of soil borings, temporary well points, and groundwater monitoring wells. These activities were performed to detect and characterize subsurface hazardous materials (if present) in soil and groundwater at RECs #8 through #11.

[2]Only one sample from REC #8 (surface-soil sample SB-91) was included in the risk assessment because its location is considered relevant to and at the boundary of REC #9. REC #9 samples were used in the risk assessment because of trichloroethene (TCE) in soils and groundwater within REC #9, as well as other chemicals of concern (COC). In REC #8, TCE and other COC were detected infrequently, and at concentrations below the relevant cleanup criteria in borings and test pits; therefore, the REC #8 area was not considered in the risk assessment.

3.1 MOBILIZATION/DEMOBILIZATION

The Tetra Tech field operations leader (FOL) coordinated mobilization and demobilization, including taking inventory of equipment to ensure that appropriate equipment was available when needed, purchasing and leasing equipment as required, and staging equipment for efficient loading and transport to the site and after each field activity was complete. Mobilization began in May 2011 and included:

- coordinating with Lockheed Martin, MSA facilities, and Maryland State Police personnel
- obtaining utility clearance in the proposed subsurface investigation locations (i.e., test pits, borings, monitoring wells) using a private utility locating firm
- mobilizing subcontractors, equipment, and materials to the site
- implementing a site-specific health and safety plan (HASP)
- arranging a decontamination area
- demobilizing equipment and materials from the site
- general site cleanup and trash removal
- surface restoration
- managing IDW as described in Section 3.10

Tetra Tech, Inc. (Tetra Tech) personnel became familiar with the site-specific HASP and the respective Safe Work Permits included in the HASP. Tetra Tech conducted a daily mandatory health and safety tailgate meeting prior to initiating any fieldwork. Subcontractors present for that day's field activities were included in these meetings. The Tetra Tech FOL documented the topics covered and personnel in attendance.

All required access agreements and permits necessary to conduct the proposed field activities were secured before beginning work. Tetra Tech performed the steps outlined below to obtain all required clearances and permits prior to initiating any intrusive field activities related to the soil investigation:

- notification of the underground utility location center Miss Utility (1-800-257-7777; www.missutility.net)

- reviewed the facility and site utility maps
- followed Enterprise Operations-28 and Lockheed Martin Minimum Requirements for Intrusive Fieldwork Work Plans, completed the digging project form, and obtained the required signatures
- completed the Airport Zoning permit, the Building Inspection form, and the Digging Authorization form through MAA
- contacted Maryland Air National Guard (MDANG) and received approval based on current military air operations
- obtained monitoring well permits
- used a private utility locating firm to identify any subsurface utilities/anomalies

Tetra Tech obtained the required permits (from Lockheed Martin, MSA, and MAA, as applicable) for the fieldwork prior to initiating any intrusive activities. Following the same procedures as for all projects to date at MSA, Tetra Tech worked closely with MSA, MAA, and their tenants to make all parties aware of the field schedule.

Prior to initiating any intrusive field activities, each test pit, soil boring, and monitoring well location was assessed for subsurface utilities. Utility maps were reviewed for the presence of utilities; boring locations were offset to avoid potential subsurface utilities. In addition to calling in a Miss Utility ticket, Enviroscan, Inc. was contracted by Tetra Tech to screen for and mark any possible utilities and other possible subsurface metallic and non-metallic geophysical anomalies.

Enviroscan, Inc. used conventional utility locating equipment representing the best available technology. Equipment included a Radiodetection RD8000 multi-frequency pipe and cable tracer, a Radiodetection C.A.T. and Genny pipe and cable locator/tracer, a Fisher TW-6 EM pipe and cable locator/tracer, and a Geophysical Survey Systems Inc. Subsurface Interface Radar System ground penetrating radar (GPR) system. Utilities within a 30-foot radius of each designated boring and test pit location were located using the appropriate technology and the ground surface was marked with paint of the appropriate colors. Where necessary, test pit, soil boring, and monitoring well locations were offset from the proposed location based on the subsurface utility mark out. The utility clearance report is in Appendix A.

Prior to initiating the field activities, site access arrangements were coordinated through MSA Operations to gain access to the GSP work area through the Wilson Point Gate. A gate access code was obtained through MSA Operations. Tetra Tech maintained constant radio communication with the MSA Air Traffic Control Tower during field activities.

3.2 TEST PITS

Twelve test pits were excavated to evaluate possibly buried materials/debris at geophysical anomalies identified in RECs #8, #9 and #10 by a survey conducted in 2010. Table 3-1 describes the rationales for the test pit locations. Test pit locations are presented in Figure 3-1.

The EM-61 survey from the 2010 Phase II Investigation indicated that REC #8 had a large metallic anomaly at its north end possibly associated with a remnant structure. This anomaly was adjacent to a cluster of anomalies extending northwest into REC #9. The survey indicated that REC #9 had several anomalies below the grass adjacent to the taxiway. One major anomaly was associated with a remnant concrete pad. These anomalies may be associated with a historical building no longer standing. REC #10 exhibited many anomalies in the grass adjacent to the taxiway. There is little correlation between the historical structure locations defined in site maps and the EM-61 anomalies identified through the field surveys.

The test pits were excavated using a rubber tired backhoe. Test pits were excavated in areas of anomalies to investigate the nature of the metallic responses, with emphasis on determining the presence of buried remains of remnant structures, tanks, and metallic debris. Test pits were excavated to the water table or below the depth of debris, if observed. Soil type and anthropogenic material encountered in the test pits was photographed and documented in a test pit log. Test pits were approximately 30 feet long and no more than 13 feet deep. The actual pit dimensions varied based on field conditions. Test Pit Log Sheets are in Appendix B; test pit observations and photographs are in Appendix C.

A Tetra Tech geologist and the FOL were present at all times during the excavating to visually monitor the excavation. The geologist inspected the test pits for evidence of waste chemicals (e.g., drums, buckets, liquids, etc.), and other metallic objects. Soil samples were collected from the zone immediately below any observed debris, or from soils with observed staining or odors, or from the base of the excavation if no debris or evidence of soil impacts was observed.

Thirteen soil samples were collected from the test pits for laboratory analysis. One soil sample was collected from each of the 12 test pits, plus one additional sample from test pit #5 (GSP-TP-5E and GSP-TP-5W). Laboratory analytical parameters for the test pit soil samples consisted of:

- volatile organic compounds (VOCs) by SW846 Method 8260C
- semivolatile organic compounds (SVOCs) by SW846 Method 8270D
- polychlorinated biphenyls (PCBs) by SW846 Method 8082A
- total petroleum hydrocarbons (TPH) –gasoline range organics (GRO) and –diesel range organics (DRO) by Method 8015
- Priority Pollutant metals by SW846 Methods 6010C/7471A

During the test pit excavations, a Tetra Tech unexploded ordnance (UXO) technician was present at all times to visually monitor the excavation. UXO was not discovered during the field activities, including the test pit excavations. All debris removed from the excavations was returned to the excavation before backfilling. Soil excavated from the test pits was backfilled the same day and compacted using the excavator bucket. Test pits were not permitted to remain open overnight.

3.3 DPT INVESTIGATION

From May 31, 2011 to June 6, 2011, soil samples were collected from 40 soil borings using DPT drilling methodology. DPT soil boring locations were distributed as follows:

- 10 borings in the area of REC #9 (former Hyper-Therm Test area, Vanguard tower, Furnace Building, and the Storage Shed area; see Figure 3-2)
- 10 borings in the area of REC #10 (former Coupon Test Shed and former Block House; see Figure 3-2)
- 20 borings in the area of REC #11 (former Buildings KC, KJ, and the transformer pad; see Figure 3-3)

Table 3-2 summarizes the locations and rationales for each DPT soil boring location. Soil boring locations are in Figures 3-2 and 3-3.

Prior to initiating subsurface drilling, soil borings in concrete covered locations were cored to provide access to the soils beneath the concrete. Soil samples were collected using DPT to an approximate depth of 25 feet below grade. Soil was collected continuously at each boring using a

1.5-inch-diameter, four-foot long, stainless steel macro-core sampler fitted with a disposable acetate liner. The sampler was advanced in four-foot increments and the retrieved soil samples were evaluated for field screening and lithologic and visual characteristics.

Soil samples were placed in a zip-top bag and screened with a photoionization detector (PID). As shown in Table 3-2, soil samples for laboratory analyses were collected at various depths from each boring. Certain depth intervals were targeted (e.g., 0–2 feet, 6–8 feet, and 20–22 feet below grade) based on observations and findings from borings advanced in the same area during the 2010 Phase II investigation. Lithologic logging was performed by a qualified Tetra Tech field geologist. All pertinent information, including boring location, soil/lithology description, sample designation and depth, PID readings, sample collection time, etc., were recorded on a Soil Sample Log Sheet and Boring Log form. The Soil Sample Log Sheets and Boring Logs are in Appendix D.

Soil samples from two different depths (e.g., typically 0–2 feet and 6–8 feet, or adjusted as needed based on conditions encountered in the field) in each soil boring were submitted for laboratory analysis. The laboratory analytical parameters for the DPT soil samples included the following:

- volatile organic compounds (VOCs) by SW846 Method 8260C
- semivolatile organic compounds (SVOCs) by SW846 Method 8270D
- polychlorinated biphenyls (PCBs) by SW846 Method 8082A
- total petroleum hydrocarbons (TPH) –gasoline range organics (GRO) and –diesel range organics (DRO) by Method 8015
- Priority Pollutant metals by SW846 Methods 6010C/7471A

In addition, as presented in Table 3-2, a third soil sample was collected deeper than 18 feet below grade in six borings in the area of REC #9 and in 13 borings advanced in the REC #11 area. The soil samples from the deepest intervals (e.g., 18–20 feet, 20–22 feet or 22–25 feet below grade) in borings at REC #9 were analyzed for VOCs and TPH-GRO/DRO only. Soil samples from the deepest intervals (e.g., 18–20, 20–22, or 22–24 feet below grade) in borings at REC #11 were analyzed for VOCs, SVOCs, and TPH-GRO/DRO. The deep soil samples were collected from select locations based on subsurface petroleum and/or VOC impacts identified in soils sampled at

similar depths during the 2010 GSP investigation. Table 3-2 presents the laboratory analytical methods used for each soil sample collected at various depths in the soil borings.

Boring locations where concrete coring was required for sampling were restored with low shrinkage concrete after backfilling. Backfilling used granular bentonite that had been hydrated to provide a seal. Patch material was finished smooth and flush with the existing grade.

3.4 MONITORING WELL INSTALLATION

From June 1–3, 2011, a Maryland-licensed well driller installed groundwater monitoring wells at eight locations (GSP-MW1 to GSP-MW-8) in the study area. The soil boring for each well was drilled using a Rota-Sonic-drill rig. A four-inch by six-inch drill rod/override casing was advanced along with temporary casing to install the well to the desired terminal depth. Table 3-3 summarizes the rationales for groundwater monitoring well locations. Figures 3-4 and 3-5 show the locations of the new monitoring wells.

During borehole advancement, soil was continuously sampled for lithologic characterization and PID screening. Soil cores were collected in each monitoring well borehole using a 10-foot core barrel. Lithologic observations from the well boreholes were recorded on the Boring Logs, presented in Appendix E.

Monitoring wells were constructed of 0.010-inch-slot schedule-40 polyvinyl chloride (PVC) well screen. Screen lengths were adjusted in the field to address the depth to groundwater and to ensure proper installation of a surface seal. At least five-feet of well screen were installed beneath the water table. A sand pack (#1 filter sand) was packed around the well screen to extend at least two feet above the top of the well screen. A 0.010-inch-slot well screen and #1 filter sand pack were used because of the site's fine-grained subsurface formations.

Following placement of the sand pack, the well was pre-developed using a surging technique to settle the sand pack around the well screen. The depth to sand was measured using a weighted tape. If settlement of the sand pack was noticed, additional sand was used to bring the sand pack back up to the desired depth. A two-feet-thick bentonite seal was installed above the sand pack and allowed to hydrate during installation. Grout consisting of Type II Portland cement and powdered bentonite was placed above the bentonite seal to approximately one-foot below the

ground surface. Grout was mixed in proportions comprised of a 94-pound bag of Type II Portland cement, nine pounds of powdered sodium bentonite, and no more than eight gallons of water. The relative thicknesses of the bentonite seal and surface seal and grout were adjusted to accommodate the well depth relative to the ground surface.

Protective eight-inch steel flush mounted well covers were secured over the well casings to protect each well. Prior to installing the flush mounted well covers, well casings were cut below grade and fitted with a water tight, expandable, sanitary seal. Concrete was installed above the grout in the annular space between the borehole and outer well casing up to approximately six-inches below grade to provide a surface seal. The wells were surface completed with a high strength concrete pad.

3.5 GROUNDWATER MONITORING WELL PURGING AND SAMPLING

Groundwater sampling consisted of one round of samples collected in the eight new monitoring wells, as well as collecting samples from eight previously installed GSP temporary well points (SB/WP-50, SB/WP-54, SB/WP-61, SB/WP-66, SB/WP-71, SB/WP-83, SB/WP-84, and SB/WP-89). Samples were collected from the newly installed wells after the wells had been allowed to equilibrate with the aquifer for at least one week following development. Groundwater was sampled June 7–24, 2011. Figures 3-6 and 3-7 show the temporary well point groundwater sampling locations.

Temporary well points were purged with a peristaltic pump using disposable polyethylene tubing. The pumping rate ranged between 100–300 milliliters per minute to minimize drawdown in the well points. During groundwater purging in all wells, water level drawdown measurements and groundwater parameters (including pH, temperature, specific conductance, dissolved oxygen, and oxidation reduction potential) were collected every three to five minutes until purging was complete. Purging was considered complete when the monitored water quality parameters stabilized, when three saturated well casing volumes were removed, or when the well had been purged dry.

Water quality parameters were measured using an inline water quality meter; turbidity was measured with a separate turbidity meter. Stabilization was considered achieved when three

consecutive readings, taken at five-minute intervals, were within ±0.1 for pH, ±3% for specific conductance and temperature, ±10% for dissolved oxygen and oxidation reduction potential, and less than 50 nephalometric turbidity units for turbidity. If a well point was purged dry, the water level was allowed to recover a minimum of 80% of its initial static water level before sampling groundwater.

Data were recorded in the appropriate site-specific logbook, Groundwater Sample Log Sheets, and on Low Flow Purge data sheets. The Groundwater Sample log sheets and Low Flow Purge data sheets are in Appendix F. All purged water was collected as IDW in U.S. Department of Transportation-approved 55-gallon steel drums, which were staged in a facility-approved location for subsequent disposal. IDW disposal is discussed in detail in Section 3.10.

As shown in Table 3-3, groundwater samples from the new wells and temporary well points were analyzed for the following parameters:

- VOCs by SW846 Method 8260C
- SVOCs and 1,4-dioxane by SW846 Method 8270D
- TPH-GRO and TPH-DRO by SW846 Method 8015
- total and dissolved Priority Pollutant metals by SW846 Method 6010C/7471A
- perchlorate by U.S. Environmental Agency (USEPA) Method 314
- hexavalent chromium by USEPA Method 218.6

Each groundwater sample analyzed for dissolved metals was filtered in the field prior to sample preservation using a dedicated, disposable, 0.45-micron filter and a peristaltic pump.

3.6 QUALITY CONTROL SAMPLES, DOCUMENTATION AND CUSTODY

Trip blanks were analyzed at a rate of one per cooler containing VOC samples. No other quality assurance/quality control samples were collected. Samples were analyzed on a standard turnaround of 21 calendar days.

Sample documentation consists of a completed laboratory chain of custody report and matrix specific sample log sheets. The chain of custody report summarizes and documents pertinent

sample information (e.g., sample identification and type, matrix, date, time of collection, preservation, and requested analysis). Sample custody procedures were followed to document sample acquisition and integrity.

3.7 SAMPLE NOMENCLATURE

Each soil sample collected during the investigation was identified with a unique sample identification tag. For this additional Phase II GSP investigation, all sample numbers were prefaced with "GSP." The sample identification tag carries the designation "SB" followed by the boring number and two numbers indicating the collection depth of the "SB" samples. For example, GSP-SB-10-8-10 would be a soil sample collected from GSP at boring location 10 and a depth interval of eight to 10 feet below grade.

Groundwater samples from the new wells were prefaced with "GSP," followed by the well identification (e.g., GSP-MW1), and then followed by the date. Groundwater samples from the temporary well points were designated by "WP," followed by the location number. For example, GSP-SB-WP-15 would be a water sample collected from well point location 15 at soil boring number 15.

3.8 SURVEYING

Following completion of the fieldwork, a Maryland-licensed professional surveyor (Murphy Geomatics of Raleigh, North Carolina) was contracted to provide horizontal and vertical coordinates for the soil borings and monitoring wells. The locations were surveyed with an accuracy to the nearest 0.01 foot for vertical elevations in the North American Vertical Datum 1988 and to the nearest 0.1 foot horizontal coordinates in the North American Datum 1983 at the top of the well casings. The Well Survey Report is in Appendix G.

3.9 SYNOPTIC WATER LEVEL MEASUREMENTS

A round of synoptic water levels was measured in the eight new monitoring wells on July 14, 2011. Water level data provides information on groundwater flow characteristics. The static water level was determined by lowering the meter's probe into the well until the liquid level indicator emitted an audible tone, indicating the air/water interface. The water level was read from the probe cable as the depth to water; water level measurements were recorded to the nearest 0.01-foot on a

groundwater level measurement field form in the appropriate site-specific field logbook. The results of the groundwater level measurement event, including a groundwater contour map, are in Section 4.1.2.

3.10 WASTE MANAGEMENT

Waste management procedures established in Lockheed Martin guidance document EROP-03 were followed in handling and managing wastes generated at the GSP site. All IDW (e.g., drill cuttings, excess soil from sampling, well development water, well purge water and decontamination fluids) was collected in new or reconditioned United States Department of Transportation approved 55-gallon steel drums. All drums were moved to a central staging area on the MSA site for waste characterization, profiling and proper disposal.

Samples of the IDW were collected and submitted for Toxicity Characteristic Leaching Procedure (TCLP) organic and inorganic analyses, corrosivity, ignitability, reactive sulfide, and reactive cyanide. Upon receipt of the IDW analytical data, the generated IDW was removed from GSP by Environmental Quality Company and disposed of at their state-licensed and Lockheed Martin-approved York, Pennsylvania facility, in accordance with federal, state, and local regulations. Personal protective equipment was brushed off, placed in trash bags, and disposed of in a facility trash receptacle.

Table 3-1
Test Pit Summary and Rationale
Greater Strawberry Point, Martin State Airport, Middle River, Maryland

Test pit number[(1)]	Test pit location	Approximate dimensions	Rationale/purpose
GSP-TP-1	Northern portion of REC #10	Length: 30 feet Depth: 12.5 feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey electromagnetic (EM) readings (EM Anomaly A)
GSP-TP-2; GSP-TP-5	South-central portion of REC #10 near historical structures 028 and 029 (Coupon Test Sheds)	Length: 30 feet Depth: 12 feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey EM readings (EM Anomaly C)
GSP-TP-3 GSP-TP-4	Northwestern edge of REC #10	Length: 30 feet Depth: 10 (TP-3) and 12 (TP-4) feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey EM readings (EM Anomaly B)
GSP-TP-6	Northwestern corner of REC #9	Length: 30 feet Depth: 11 feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey EM readings
GSP-TP-7; GSP-TP-8	Western portion of REC #9 near historical structure 025 (Hyper-Therm Test Facility)	Length: 30 feet Depth: 10 (TP-7) and 7.5 (TP-8) feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey EM readings (EM Anomaly D [GSP-TP-7] and southwest of Anomaly D [GSP-TP-8])
GSP-TP-9	Southeastern portion of REC #9	Length: 17 feet Depth: 10 feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey EM readings (northwest of EM Anomaly E)
GSP-TP-10	Northwestern portion of REC #8	Length: 17 feet Depth: 12.5 feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey EM readings (EM Anomaly E)
GSP-TP-11	South-central portion of REC #8 between historical structures 023 (Compressor Shed) and 024 (Engine Test)	Length: 30 feet Depth: 8 feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey EM readings near an existing building and former structures
GSP-TP-12	Near southern boundary of REC #8 southwest of an existing building	Length: 21 feet Depth: 9 feet	Assess the possible presence of buried materials/structures based on elevated geophysical survey EM readings

[1]Soil samples were collected if debris or wastes were encountered, or impact was suspected based on field PID readings or other indicators of impact (staining, odor, etc.). Samples were analyzed for VOCs (USEPA Method 8260C), SVOCs (USEPA Method 8270D), PCBs (USEPA Method 8082A), metals (USEPA Method 6010C), mercury (USEPA Method 7471A), and TPH-GRO/DRO (USEPA Method 8015).

Table 3-2
Summary of Soil Sampling, Chemical Analyses, and Sampling Rationales
Greater Strawberry Point, Martin State Airport, Middle River, Maryland
Page 1 of 2

Soil boring number	Soil boring location	Boring depth	Sampling depth(s) (feet below grade)	Sample analysis (method)	Rationale/ Purpose
GSP-SB-91 and GSP-SB-92	Northern portion of REC #8	25 feet	0–2 6–8[(1)] 18–25[(1,2)]	*VOCs* (8260C) *SVOCs* (8270D) *PCBs* (8082A) *Metals* (6010C) *Mercury* (7471A) *TPH-GRO/DRO* (8015) *VOCs* and *TPH-DRO/GRO* only for 18'–25' samples	Assess extent of PAHs in surface soil at SB-57; TCE detected in soil at 10–12 feet and 20–22 feet at SB-56 and 23–25 feet at SB-57/58; and TPH-GRO at 20–22 feet at SB-56
GSP-SB-93 through GSP-SB-96	Eastern and southeastern portion of REC #9 surrounding 2010 borings GSP-SB-56, GSP-SB-57, and GSP-SB-58	25 feet	0–2 6–8[(1)] 20–24[(1,2)]	*VOCs* (8260C) *SVOCs* (8270D) *PCBs* (8082A) *Metals* (6010C) *Mercury* (7471A) *TPH-GRO/DRO* (8015) *VOCs* and *TPH-DRO/GRO* only for 18'–25' samples	Assess extent of PAHs in surface soil at SB-57; TCE detected in soil at 10–12 feet and 20–22 feet at SB-56 and 23–25 feet at SB-57/58; and TPH-GRO at 20–22 feet at SB-56
GSP-SB-97 through GSP-SB-100	Western and northern portion of REC #9	25 feet	0–2 6–8[(1)]	*VOCs* (8260C) *SVOCs* (8270D) *PCBs* (8082A) *Metals* (6010C) *Mercury* (7471A) *TPH-GRO/DRO* (8015)	Provide additional soil data coverage for western side of REC #9, and delineate extent of PAHs that exceeded screening criteria in shallow 2010 samples at GSP-SB-61 and GSP-SB-67

[1]Sampling depth was modified based on field photo-ionization detector (PID) readings or other indicators of impacts (staining, odor, etc.). Actual depths are listed in the boring logs in Appendix D.

[2]Deep samples (e.g., 18'–25') were collected at GSP-SB-91 through GSP-SB-96, GSP-SB-111, GSP-SB-113 to GSP-SB-115, GSP-SB-117 through GSP-SB-122, GSP-SB-126, and GSP-SB-129 through GSP-SB-130.

Section 4
Results

The following sections describe the physical and chemical characteristics of soil and groundwater as determined from the results of this additional Phase II investigation. Section 4.1 briefly discusses the geologic and hydrologic results from the soil boring and groundwater gauging programs at Greater Strawberry Point (GSP). The results of the test pit investigation and chemical analyses of soil and groundwater in the areas of Recognized Environmental Conditions (RECs) #8, #9, #10, and #11, are discussed in Sections 4.2 through 4.4.

Sections 4.2 through 4.6 present the results of the chemical analyses of site soil and groundwater samples relative to human health risk-based screening standards. Human health screening was completed for this investigation because human health risks are considered primary drivers for implementing additional studies and remedial actions. In Sections 4.2 through 4.6, Maryland Department of the Environment (MDE) chemical-specific soil and groundwater standards (MDE, 2008) were used to evaluate concentrations of constituents detected in soil and groundwater. MDE uses these standards to screen sites, and they are useful benchmarks for evaluating site data and potential cleanup goals. The screening objectives are to: (1) gauge the degree of observed impacts in relation to regulatory standards and potential adverse effects on human health or the environment; and (2) to evaluate the need for further sampling or remedial action. Therefore, regulatory risk-based standards are used whenever possible.

For soil, the results of the field investigation were compared to residential and non-residential land use standards. Residential standards are used to provide a relative evaluation for hypothetical future property use. Non-residential screening of the results was conducted because the site is restricted and the facility is likely to remain a state government facility for the indefinite future. Non-residential standards are considered more applicable for current and likely future uses of the property.

Soil results for particular metals were also compared to MDE's anticipated typical concentration (ATC) (State of Maryland, 2008). ATCs are based on naturally occurring levels of metals (e.g., arsenic) in Maryland soils that commonly exceed residential and non-residential risk-based concentrations. MDE developed ATCs to represent reference levels or "background" concentrations for seven metals in three geologic regions of Maryland.

MDE allows for the proposed use of an ATC concentration as an alternative to the residential risk-derived soil standard if the ATC exceeds the risk-derived standard. For example, the arsenic ATC for the eastern region of Maryland, where Martin State Airport (MSA) is located, is 3.6 milligrams per kilogram (mg/kg). For visual identification of metals exceedances in soils (see Figures 4-2 through 4-9), the detected metals concentrations were screened against the eastern Maryland ATCs only. Metals concentrations exceeding the MDE residential/non-residential criteria are not shown on the maps in Section 4.0 except where they also exceed the ATC criteria.

Two types of tables summarizing the chemical analytical results are provided in Sections 4.2 through 4.6. In the first table, statistical summaries detail the number of detections, minimum and maximum concentrations, and average concentrations for each analyte detected. The second table provides a complete listing of concentrations detected in soil and data validation qualifiers for the samples collected during this investigation. Shaded cells in these tables represent constituents for which concentrations exceed MDE screening standards. Data tables presenting all sample analytical results, along with laboratory reporting limits or method detection limits, are in Appendix H. Data validation reports are in Appendix I.

4.1 GEOLOGY AND HYDROLOGY

4.1.1 Geology

The lithology encountered in the soil borings varies across the RECs. In the REC #9 area, gray and brown silty sand and sandy silt with occasional clay lenses is encountered to a depth of 25 feet. The REC #10 subsurface lithology is similar to REC #9, except for a more prominent clay layer, ranging between two and 6.5 feet thick, found primarily 10–20 feet below grade. The REC #11 subsurface lithology varies somewhat, ranging from an area in the north comprised of gray and brown silty sand and sandy silt overlying a thick clay layer (SB-120 and SB-121) to an area farther south (SB-122 and SB-123) that is comprised of nearly all silty sand to a depth of 25 feet.

4.1.2 Hydrology

Static groundwater levels were measured in the newly installed monitoring wells (GSP-MW-1 through GSP-MW-8) on July 14, 2011. The static levels (i.e., depth to water) were measured from the top of each well casing using an electronic water level meter. Using vertical survey coordinates, groundwater level measurements were converted to elevations, as shown in Table 4-1. Groundwater depths to water from the top of the casings ranged from 3.36 feet at GSP-MW4 to 6.92 feet at GSP-MW2. Groundwater elevations ranged from 2.74 feet above mean sea level (MSL) at GSP-MW3 and 5.14 feet above MSL at GSP-MW1 (both at REC #11) to 4.41 feet above MSL at GSP-MW8 (REC #9).

Figure 4-1 shows the groundwater-elevation contours using the July 2011 measurements in Table 4-1. Groundwater flows from areas of higher groundwater elevations (i.e., higher groundwater potential) to areas of lower groundwater elevations. As shown in Figure 4-1, groundwater in the GSP study area generally flows toward Stansbury Creek to the south. The contours indicate an area of possibly localized groundwater mounding in the REC #11 area. Drainage culverts from the runways in this area contribute to the localized mounding effect in times of heavy precipitation.

4.2 TEST PIT INVESTIGATION RESULTS

As described in Section 3.2 and Table 3-1, 12 test pits were advanced to provide subsurface characterization and chemical analytical data for soils near anomalies identified during the 2010 GSP investigation. Thirteen soil samples from the test pits were submitted for the following analyses:

- volatile organic compounds (VOCs) by SW846 Method 8260C
- semivolatile organic compounds (SVOCs) by SW846 Method 8270D
- polychlorinated biphenyls (PCBs) by SW846 Method 8082A
- total petroleum hydrocarbons (TPH) –gasoline range organics (GRO) and –diesel range organics (DRO) by Method 8015
- Priority Pollutant metals by SW846 Methods 6010C/7471A

Seven test pits were advanced in the area of RECs #8 and #9, and five test pits were advanced in the area of REC #10. The observations and results from the test pit sampling program are separated below according to the area of investigation (i.e., each REC #/area). Test pit logs are in Appendix B and test pit photographs and observations are in Appendix C. The laboratory analytical results for the test pit soil samples are summarized in Tables 4-2 and 4-3. In Table 4-2, sampling results are compared to MDE residential and non-residential soil screening criteria.

Figure 4-2 shows the 2011 soil sampling results from the test pits in the REC #8 and REC #9 areas that exceed the comparison criteria. Figure 4-3 shows the results for REC #10 area. For metals, only exceedances of the ATCs for eastern Maryland soils are shown. The discussion below is segregated by REC area to correspond with the figures.

4.2.1 Test Pits in REC #8 and #9 Areas

REC #8 contains the former Control House (Building 14), former Noise Suppression Building (Building 15), former Jet Test Shed (Building 16), former Storage Building (Building 17), former Compressor Shed (Building 23), and former Engine Test Building (Building 24), and encompasses approximately 2.3 acres in the central portion of GSP. REC #9 is the former Propellant Storage Building (Building 18), former Acetylene Storage Building (Building 20), and former Furnace Building (Building 19), an area encompassing approximately 2.8 acres, is adjacent to REC #8 along the southern edge of Taxiway F. The former Vanguard Tower (Building 21) and former Hyper-Therm Test Facilities (Building 25) are in the northwestern portion of REC #9 (see Figures 2-2 and 3-2). These buildings were built in the mid-1950s, based on historical aerial photographs, but have since been demolished. An underground water line runs into REC #8 from the southern area of REC #9.

At REC #8, test pits were advanced as follows: GSP-TP-11 in the south-central portion of REC #8 between historical structures 023 (Compressor Shed) and 024 (Engine Test); GSP-TP-12 near the southern boundary of REC #8 southwest of an existing building; and GSP-TP-10 in the northwestern portion of REC #8, near REC #9. At REC #9, test pits were advanced as follows: GSP-TP-6 near the northwestern corner of REC#9, near REC #10; GSP-TP-7 and –TP-8 in the western portion of REC #9 near historical structure 025 (Hyper-Therm Test Facility); and GSP-TP-9 in the southeastern corner of REC #9. Figure 4-2 shows the locations of the test pits at RECs #8 and #9.

Test pit soil samples from GSP-TP-10-10-12 (10–12 feet below grade), GSP-TP-11-7-8 (seven to eight feet below grade), and GSP-TP-12-8-9 (eight to nine feet below grade), all in the area of REC #8, were submitted for laboratory analysis. Five VOCs and nine metals were detected in sample GSP-TP-10-10-12 collected in REC #8. The laboratory results for three of the detected VOCs were "B"-qualified, indicating they were also found in the laboratory blank. All VOC concentrations detected in GSP-TP-10 are below MDE residential and non-residential soil criteria. The metals concentrations detected in this sample are also below criteria, except for arsenic and vanadium. Arsenic at 1.9 milligrams per kilogram (mg/kg) equals the non-residential criterion, and vanadium at 10 mg/kg, exceeds its residential criterion. However, the arsenic and vanadium concentrations detected in GSP-TP-10-10-12 are below their respective ATCs for eastern Maryland (3.6 and 30 mg/kg, respectively).

Only two VOCs were detected in soil samples collected from GSP-TP-11-7-8 and GSP-TP-12-8-9, and both were "B"-qualified, indicating laboratory blank contamination. Eight metals were detected, with only one metal concentration (vanadium) exceeding MDE residential soil criteria. However, the detected vanadium concentration (11 mg/kg) is below the ATC for vanadium (30 mg/kg).

Soil samples were collected in four test pits in the REC #9 area and submitted for laboratory analysis: GSP-TP-6-4-6, GSP-TP-7-9-10, GSP-TP-8-6-7, and GSP-TP-9-8-10. Laboratory results for GSP-TP-6-4-6 (collected below observed concrete and metal debris) indicate 14 VOCs, 17 SVOCs, 13 metals, and diesel range organics (DRO). The detected concentrations of all VOCs, except naphthalene, are either estimated (i.e., "J"-flagged) or associated with the laboratory blank ("B"-qualified). None exceed MDE's residential or non-residential soil criteria. Five SVOCs were detected in GSP-TP-6-4-6 at concentrations exceeding the residential criteria; the concentrations of one of these five, benzo(a)pyrene, exceed both the residential and non-residential criteria. In addition, three metals were detected at concentrations exceeding their respective MDE residential criteria: arsenic (2.6 mg.kg), thallium (0.69J mg/kg), and vanadium (16 mg/kg). However, the detected concentrations of these metals are all below their ATCs (3.6, 3.9, and 30 mg/kg for arsenic, thallium, and vanadium, respectively).

VOCs and SVOCs were detected sporadically in soil samples GSP-TP-7-9-10, GSP-TP-8-6-7, and GSP-TP-9-8-10. Three or fewer VOCs were detected in each sample; in each case, the

results were "B"-flagged. Four or fewer SVOCs were detected in each sample; all SVOC results are estimated (i.e., "J"-qualified) except fluoranthene, and all are below the MDE residential criteria. Between six and nine metals were detected in these three samples. Arsenic concentrations exceed the residential and/or non-residential soil criteria, but are less than the ATC. Concentrations of the other metals are below the selected criteria.

4.2.2 Test Pits in REC #10 Area

REC #10 includes the former Coupon Test Sheds (Buildings 27, 28, and 29) and former Block House (Building 26) area, encompassing approximately 1.4 acres in the northern portion of GSP (see Figures 2-2 and 3-2). At REC #10, test pits were advanced as follows: GSP-TP-1 in the northern portion of REC #10, GSP-TP-2 (near historical structure 029, the Coupon Test Equalization Shed) and GSP-TP-5 (near historical structure 028, the Coupon Test Shed) both in the central portion of REC #10; GSP-TP-3 and GSP-TP-4 at the northwestern edge of REC #10. Two soil samples were collected from test pit GSP-TP-5: one at the east end of the pit (GSP-TP-5E-10-12) and one at the west end (GSP-TP-5W-10-12). Figure 4-3 presents the REC #10 test pit locations.

At REC #10, soil samples from GSP-TP-1-10-12, GSP-TP-2-10-12, GSP-TP-3-5-7, GSP-TP-4-3-5, and GSP-TP-5E-10-12 and GSP-TP-5W-10-12 were all submitted for analysis. Laboratory results for GSP-TP-1-10-12 indicate that only three VOCs and nine metals were detected in this sample. All three VOCs (acetone, methylene chloride, and toluene) had concentrations that were either "B"- or "J"-qualified, and four of the detected metals had low, estimated ("J"-qualified) concentrations. None of the analytes detected in GSP-TP-1-10-12 were at concentrations exceeding the comparison criteria.

The results for GSP-TP-2-10-12 and GSP-TP-3-5-7 are similar to GSP-TP-1-10-12: the same three VOCs, and a similar number of metals (11 in GSP-TP-2-10-12 and nine in GSP-TP-3-5-7), were detected in these samples. VOC concentrations are less than the comparison criteria. None of the detected metal concentrations exceed criteria, except for arsenic and vanadium. Vanadium exceeded the MDE residential criterion in both samples, and the detected arsenic concentration in GSP-TP-3-5-7 is equal to the MDE non-residential criterion. However, the detected arsenic and vanadium concentrations in these samples are less than their respective ATCs. Laboratory analytical results for the remaining three soil samples from test pits at REC #10 indicate as many

as 12 VOCs, 19 SVOCs, TPH-DRO and/or -GRO, and 15 metals. Detected VOC concentrations in all three soil samples (GSP-TP-4-3-5, GSP-TP-5E-10-12, and GSP-TP-5W-10-12) are all less than residential and non-residential comparison criteria.

In the soil sample from GSP-TP-4-3-5, which was collected from underneath miscellaneous debris (e.g., tires, Styrofoam®, and asphalt; see Appendix C), five SVOCs were detected at concentrations exceeding MDE residential criteria (benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, dibenzo[a,h]anthracene, and indeno[1,2,3-cd]pyrene), and one SVOC exceeded both residential and non-residential criteria (benzo[a]pyrene). The TPH-DRO concentration in GSP-TP-4-3-5 also exceeds residential and non-residential criteria. Fifteen metals were detected in this sample. Of these, the detected arsenic, thallium, and vanadium concentrations (3.1, 0.92 J, and 27 mg/kg, respectively) exceed residential criteria, and arsenic exceeds both its residential and non-residential standard. However, the concentrations of arsenic, thallium, and vanadium are less than their ATCs of 3.6, 3.9, and 30 mg/kg, respectively. The chemical analytical results for GSP-TP-4-3-5 indicate that shallow soils in this test pit may have been impacted by former operations associated with the Coupon Test Equalization Shed (structure 029 in Figure 2-2) or its demolition, and/or by miscellaneous debris observed in shallow fill materials in this test pit (see Appendices B and C). The presumed concrete slab of this former shed was encountered during test pit excavation at this location.

Twelve VOCs and 14 SVOCs were detected at concentrations below the comparison criteria in soil sample GSP-TP-5E-10-12. Five SVOCs (benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, dibenzo[a,h]-anthracene, and indeno[1,2,3-cd]pyrene) were detected at concentrations exceeding residential criteria, and one SVOC (benzo[a]pyrene) exceeds both its residential and non-residential criteria. The TPH-DRO concentration reported in GSP-TP-5E-10-12 also exceeds the residential and non-residential criteria. TPH-GRO was reported at a concentration less than the comparison criteria. Concentrations of four metals (arsenic, chromium, thallium, and vanadium) exceed residential criteria. The arsenic and thallium concentrations in GSP-TP-5E-10-12 do not exceed their respective ATCs. However, the detected chromium concentration (28 K mg/kg) is equal to its ATC (28 mg/kg), with the “K” qualifier indicating that the detected result is considered biased low as a result of laboratory technical

non-compliance. Vanadium (34 mg/kg) in GSP-TP-5E-10-12 slightly exceeds its ATC (30 mg/kg). Eight other metals were detected at low concentrations below MDE criteria.

Chemical analytical results for the western GSP-TP-5 sample (GSP-TP-5W-10-12) are similar to those for the eastern sample (GSP-TP-5E-10-12), with several of the same VOC detections, along with SVOCs, TPH-GRO, TPH-DRO, and 13 metals. Detected VOC concentrations are less than the residential and non-residential screening criteria. Five SVOCs (benzo[a]anthracene, benazo[a]pyrene, benzo[b]fluoranthene, dibenzo[a,h]-anthracene, and indeno-[1,2,3-cd]pyrene) were detected at concentrations exceeding residential criteria, and one SVOC (benzo[a]pyrene) exceeded residential and non-residential criteria. TPH-DRO was reported in GSP-TP-5W-10-12 at a concentration in excess of its residential criterion, and TPH-GRO was reported at a concentration less than its comparison criterion.

Concentrations of arsenic, thallium, and vanadium exceed residential criteria, with the arsenic concentration also exceeding its non-residential criterion. The arsenic and thallium concentrations reported in GSP-TP-5W-10-12 are less than their ATCs, but the vanadium concentration reported in this sample (36 mg/kg) exceeds its ATC (30 mg/kg). The soil analytical results discussed above and the abundance of concrete and metal debris noted throughout test pit GSP-TP-5 (see Appendices B and C) soils in this area of REC #10 suggest that SVOC, petroleum hydrocarbon, and metal impacts is likely attributable to the observed fill material and/or historical operations at REC #10.

4.3 SOIL BORING AND SOIL SAMPLING RESULTS

As described in Section 3.3 and Table 3-2, 40 soil borings were advanced in the study area. In each boring, surface and subsurface soil samples were collected at depths ranging from 0–2 to 22–25 feet. Ninety-nine soil samples were collected during this investigation for laboratory analyses. Soil samples from each of the soil borings were submitted for the following analyses:

- VOCs by SW846 Method 8260C
- TPH -GRO and -DRO by Method 8015
- PCBs by SW846 Method 8082A
- SVOCs by SW846 Method 8270D
- Priority Pollutant metals by SW846 Methods 6010C/7471A

As shown in Table 3-2, select deep soil samples from RECs #9 and #11 were submitted for limited chemical analyses (e.g., VOCs, SVOCs, and TPH-DRO/GRO at REC #11, and VOCs and TPH-DRO/GRO at REC #9).

Table 4-4 is a statistical summary of contaminants detected in the soil samples collected and analyzed from soil borings during this investigation. Table 4-5 highlights analyte concentrations that exceed Maryland residential and non-residential land use standards. In the discussion below, and in Figures 4-4 through 4-9, benzo(a)pyrene equivalents (BaPEq) are used for comparison instead of individual polycyclic aromatic-hydrocarbon (PAH) compounds, because the list of detected individual compounds for PAHs are typically consistent throughout the RECs, and because the BaPEq concentration is used in the risk assessment calculations. The methodology for calculating the BaPEq is in Section 5.1.2.2. In addition, for metals, only exceedances of the ATCs for eastern Maryland soils are shown in Figures 4-4 through 4-9.

Ten soil borings were advanced in the REC #9 area (GSP-SB-91 through GSP-SB-100), ten in the REC #10 area (GSP-SB-101 through GSP-SB-110), and 20 borings in the REC #11 area. The observations and results from the soil boring sampling program are separated below according to the area of investigation (i.e., each REC #/area). In Figures 4-4 through 4-9, soil results are segregated by REC area and sampling depth (e.g., surface soils [0–2 feet below grade]; subsurface [2–15 feet below grade]; and deep subsurface [greater than 15 feet below grade]).

4.3.1 Borings in REC #8, REC #9, and REC #10 Area

Northern REC #8 and southern REC #9 area—Soil samples were collected from two borings at the northern border of REC #8 (GSP-SB-91 and GSP-SB-92) and from four borings advanced in the southern half of REC #9 (GSP-SB-93 through GSP–SB-96), from two different depths (surface [0–2 feet] and subsurface [6–14 feet below grade]). All samples were submitted for the full list of laboratory analyses. One deeper sample (greater than 18 feet below grade) was collected in each of these six borings and submitted for analysis of VOCs and TPH-DRO/GRO only. Table 4-5 shows the sampling results from these six borings and indicates the analytes with detected concentrations that exceed comparison criteria. The chemical detections exceeding MDE comparison criteria and metals ATCs for soil samples collected over various depth ranges in these six borings are shown in Figure 4-4 (surface soils 0–2 feet), Figure 4-5 (2–15 feet), and Figure 4-6 (greater than 15 feet).

VOCs were not detected at concentrations exceeding MDE comparison criteria in any of the soil samples analyzed from these six borings, with one exception. The trichloroethene (TCE) concentration exceeds its residential screening criteria in the soil sample GSP-SB-92-22-25 (22-25 feet below grade), near the northern border of REC #8. TCE concentrations in three other samples, GSP-SB-93-12-14, GSP-SB-93-22-24, and GSP-SB-95-20-22, exceed the United States Environmental Protection Agency (USEPA) soil-to-groundwater soil-screening level (SSL) of 1.8 micrograms per kilogram (µg/kg) but are below the MDE residential screening level. These borings were in the southern portion of REC #9 near former Buildings 018 (former Propellant Storage) and 019 (former Furnace Building), a location near which TCE was also detected above screening levels during the 2010 investigation. Five other VOCs were detected in one or more soil samples from the six borings in this area, but at concentrations below the comparison criteria. GRO constituents were not detected in any of the REC #8 or REC #9 soil boring samples; DRO was detected in 10 of the samples at low and/or estimated ("J"-flagged) concentrations, which are less than the comparison criteria.

Benzo(a)pyrene is the only SVOC detected at concentrations exceeding the non-residential criteria. The exceedances occurred in four of the surface soil samples (0–2 feet) collected from borings in the southern portion of REC #9. The benzo(a)pyrene concentrations detected in these samples are less than the non-residential screening criteria. The BaPEq values (calculated based on positive detects only) for the northern REC #8 and southern REC #9 samples are less than the screening benchmark of 140 µg/kg, based on the 1×10^{-5} cancer-risk level for residential soils. PCBs were not detected in either of the northern REC #8 borings (GSP-SB-91 and GSP-SB-92). Aroclor-1260 was detected at a low, estimated concentration (63 J mg/kg) in the surface soil sample collected in boring GSP-SB-96, in the southwestern portion of REC #9. The REC #9 borings had no other detections of PCBs.

As many as 13 metals were detected in soil samples from the six northern REC #8 and southern REC #9 area borings. Overall, the highest metal concentrations in this area were detected in the samples from GSP-SB-91 (at 0–2 feet and 8–10 foot depths), along the northern border of REC #8 and next to REC #9. The surface soil sample with the greatest occurrence of metals (with 13 metals detected) is GSP-SB-94-0-2, in the southwest portion of REC #9. Detected concentrations of arsenic in five soil samples from borings in this area exceed both the

residential and non-residential criteria for arsenic. Arsenic in six other soil samples from this area exceeds the residential criterion only. Of the 11 soil samples collected in this area with arsenic concentrations exceeding residential and/or non-residential criteria, only two concentrations, in samples GSP-SB-91-8-10 and GSP-SB-95-6-8, exceed the eastern Maryland ATC of 3.6 mg/kg.

Other metals detected in excess of residential comparison criteria in this area include chromium in one sample (GSP-SB-91-8-10 at 39 mg/kg) and vanadium concentrations in six samples (GSP-SB-91-0-2, GSP-SB-91-8-10, GSP-SB-93-0-2, GSP-SB-94-0-2, GSP-SB-95-6-8, and GSP-SB-96-0-2). Vanadium concentrations in these samples range from 8.6–93 mg/kg. Chromium and vanadium concentrations (39 mg/kg and 93 mg/kg, respectively) in GSP-SB-91-8-10 also exceed their respective ATC criteria of 28 mg/kg and 30 mg/kg.

Northern REC #9 area—In the four borings advanced in the northern portion of REC #9 (GSP-SB-97 through GSP-SB-100), soil samples were collected from two different depths (surface [0–2 feet] and subsurface [6–8 feet below grade]) and submitted for the full list of laboratory analyses specified in Section 4.0. Table 4-5 shows the analytes detected at concentrations exceeding comparison criteria in these four borings. The chemical detections exceeding MDE comparison criteria and ATCs for metal in soil samples collected over various depth ranges in these four borings are shown in Figure 4-4 (surface soils 0–2 feet), Figure 4-5 (2–15 feet), and Figure 4-6 (greater than 15 feet).

VOCs were not detected at concentrations exceeding comparison criteria in any of the soil samples analyzed from the four borings in the northern portion of REC #9. Five VOCs were detected in one or more soil samples from these four borings, but at concentrations below the comparison criteria. GRO constituents were not detected in any of the northern REC #9 soil boring samples. DRO constituents were detected at low, estimated ("J"-qualified) concentrations in two area soil-boring samples (GSP-SB-97-0-2 and GSP-SB-98-6-8). DRO was also detected in two other soil boring samples (GSP-SB-99-0-2 and GSP-SB-99-6-8), but the concentrations were qualified with a "B," indicating the result is attributed to contamination in the laboratory blank. The TPH-DRO concentrations detected in these four samples are all below MDE screening criteria.

Benzo(a)pyrene was detected at a concentration exceeding its non-residential criterion in only two surface soil samples (GSP-97-0-2 and GSP-SB-99-0-2) in the northern REC #9 area. The

concentrations of other SVOCs detected in soil samples from the four northern REC #9 borings are all less than screening criteria. The BaPEq values (calculated based on positive detects only) for the northern REC #9 samples are less than the screening benchmark of 140 µg/kg, based on the 1×10^{-5} cancer-risk level for residential soils. PCBs were not detected in any of the northern REC #9 soil boring samples.

Fourteen different metals were detected in the soil samples from borings in the northern portion of REC #9. Overall, the sample from this area with the most metals detected and the highest concentrations is GSP-SB-99-0-2. Arsenic concentrations detected in four soil samples from the northern REC #9 borings exceed both the residential and non-residential criteria for arsenic. Arsenic in four other northern REC #9 soil samples exceeded the residential criterion only. None of the eight soil samples in this area with MDE exceedances for arsenic had arsenic concentrations in excess of the eastern Maryland ATC of 3.6 mg/kg for arsenic. Vanadium was also detected at concentrations exceeding residential comparison criteria in six of the eight samples from this area (GSP-SB-97-6-8, GSP-SB-98-0-2, GSP-SB-98-6-8, GSP-SB-99-0-2, GSP-SB-99-6-8, and GSP-SB-100-2-4). Vanadium concentrations in these samples range from 8.9–14 mg/kg, all below the ATC of 30 mg/kg.

REC #10 area—Twenty soil samples were collected from 10 borings in the REC #10 Area and submitted for the full list of laboratory analyses specified in Section 4.0. Soil samples were collected at 0–2 feet and 6–8 feet below grade in each boring (GSP-SB-101 through GSP-SB-110). Table 4-5 shows the analytes with detected concentrations exceeding comparison criteria in these 10 borings. Chemicals detected (in soil samples collected over various depth ranges from REC #10 area borings) at concentrations in excess of ATCs for metals and MDE comparison criteria are shown in Figure 4-4 (surface soils 0–2 feet), Figure 4-5 (2–15 feet), and Figure 4–6 (greater than 15 feet).

VOCs were detected infrequently (no more than four detections per boring) in the REC #10 soil boring samples, or the VOCs detected (acetone, methylene chloride, and naphthalene) were qualified as being associated with laboratory control blanks and therefore considered artifacts of the laboratory analyses. None of the detected VOC concentrations exceed the comparison criteria. GRO constituents were not detected in any of the REC #10 soil boring samples. DRO was detected in 15 of the 20 samples from REC #10 borings, with seven of the positive results

designated with a "B" qualifier, indicating the result is attributed to contamination in the laboratory blank. In the remaining eight samples in which TPH-DRO was detected, concentrations in four of the REC #10 samples (GSP-SB-102-6-8, GSP-SB-109-0-2, GSP-SB-109-6-8, and GSP-SB-110-0-2) exceed the residential standard. The remaining four samples had TPH-DRO concentrations less than the comparison criteria.

SVOCs were detected at low to moderate concentrations in approximately half of the REC #10 soil boring samples. Concentrations of one or more SVOCs exceed residential and non-residential standards in only three of the REC #10 borings (GSP-SB-102, GSP-SB-106, and GSP-SB-109), with the greatest occurrence and highest concentrations of SVOCs reported in GSP-SB-109-6-8 (6–8 feet below grade). This boring was in the western portion of REC #10.

As shown in Table 4-5, SVOCs frequently detected in the REC #10 soil samples include benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, fluoranthene, phenanthrene, and pyrene. Concentrations of benzo(a)pyrene exceed the non-residential criterion in six of the 20 REC #10 soil samples, and exceed both residential and non-residential criteria in four of the samples (GSP-SB-102-6-8, GSP-SB-106-0-2, GSP-SB-109-0-2, and GSP-SB-109-6-8).

In sample GSP-SB-102-6-8, collected near the central portion of REC #10 between the former Block House and Coupon Test Shed, the detected concentrations of benzo(a)anthracene, benzo(b)fluoranthene, and indeno(1,2,3-cd)pyrene exceed only the non-residential criteria, and benzo(a)pyrene and dibenzo(a,h)anthracene concentrations exceed both residential and non-residential criteria. Similarly, in sample GSP-SB-106-0-2, collected in the northeast portion of REC #10, the same three SVOCs exceed non-residential criteria, and the benzo(a)pyrene concentration exceeds residential and non-residential criteria. In boring GSP-SB-109, benzo(a)pyrene is the only SVOC to exceed both residential and non-residential criteria in the surface soil sample (0–2 feet), whereas in the deeper sample (6–8 feet below grade), five SVOCs exceed both the residential and non-residential criteria. These five SVOCs are benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene.

BaPEq values (calculated based on positive detects only) in four surface soil samples (GSP-SB-101-0-2, GSP-SB-102-0-2, GSP-SB-106-0-2, and GSP-SB-109-0-2) exceed the BaPEq screening benchmark of 140 µg/kg. The BaPEq values calculated for three of the subsurface soil boring samples in REC #10 (GSP-SB-102-6-8, GSP-SB-109-6-8, and GSP-SB-110-6-8) exceed the BaPEq screening benchmark. BaPEq values for the remaining REC #10 samples are less than the screening benchmark for BaPEq.

PCBs were not detected in any REC #10 area soil boring samples, except for Aroclor-1260, which was detected in only one subsurface soil sample (GSP-SB-109-6-8) at a low concentration below MDE screening criteria. Concentrations of four metals (arsenic, total chromium, thallium, and vanadium) exceed soil standards in one or more samples. Arsenic concentrations in nearly all samples exceed both the residential and non-residential soil standards. However, arsenic in soil is not considered a concern because concentrations in this REC are similar to the eastern Maryland ATC for arsenic; therefore, these arsenic concentrations are not considered the result of site-related activities.

The total chromium concentration, in only one subsurface soil sample (GSP-SB-108-6-8), exceeds both the non-residential soil standard and the ATC. In two other samples (GSP-SB-105-6-8 and GSP-SB-108-0-2), total chromium concentrations exceed the non-residential criterion, but not the residential criterion. Thallium concentrations in five samples exceed the non-residential criterion, but are below the residential standard and the ATC. Vanadium concentrations exceed the non-residential soil standard in all 20 of the REC #10 soil boring samples, but none of the vanadium concentrations exceed the residential soil standard. Only four samples (GSP-SB-105-6-8, GSP-SB-108-0-2, GSP-SB-108-6-8 and GSP-SB-110-0-2) had vanadium concentrations in excess of its ATC (30 mg/kg).

4.3.2 Borings in REC #11 Area

Fifty-four soil samples were collected from 20 soil borings (GSP-SB-111 to GSP-SB-130) in the REC #11 Area and submitted for the full list of laboratory analyses specified in Section 4.0. Soil samples were collected in each boring at two different depths (surface [0–2 feet] and subsurface [6–12 feet below grade]). One deeper sample (greater than 18 feet below grade) was also collected in select borings and submitted for analysis of VOCs, SVOCs, and TPH-DRO/GRO. Sampling results for these borings, including identification of analytes with detected

concentrations exceeding screening criteria, are in Table 4-5. Chemical detections exceeding the MDE comparison criteria and/or the metals' ATCs for soil samples collected over various depth ranges from borings in the REC #11 area are in Figure 4-7 (surface soils 0–2 feet), Figure 4-8 (2-15 feet), and Figure 4-9 (greater than 15 feet).

VOCs were detected infrequently, at low concentrations, or were "B" qualified (present in the laboratory control blanks and thus considered artifacts of the laboratory analyses). None of the VOC concentrations detected in the REC #11 soil boring samples exceed the MDE comparison criteria. However, the detected concentrations of TCE in seven REC #11 soil boring samples (GSP-SB-113-22-24, GSP-SB-115-18-20, GSP-SB-118-20-22, GSP-SB-119-6-8, GSP-SB-124-6-8, GSP-SB-126-20-22, and GSP-SB-130-20-22) exceed the USEPA soil-to-groundwater SSL of 1.8 µg/kg. TPH-GRO was detected in only four samples, at low concentrations below comparison criteria. TPH-DRO was detected in 30 of 54 REC #11 samples, with two samples (GSP-SB-115-0-2 and GSP-SB-124-0-2) having exceedances for both the residential and non-residential standards. Five additional samples exceeded the non-residential standard only.

SVOCs were detected at low to moderate concentrations in approximately half of the REC #11 soil boring samples. Concentrations of one or more SVOCs exceed residential and non-residential standards in 10 of the REC #11 borings (GSP-SB-112, GSP-SB-115, GSP-SB-117, GSP-SB-118, GSP-SB-119, GSP-SB-120, GSP-SB-121, GSP-SB-122, GSP-SB-124, and GSP-SB-125). The greatest occurrence and highest concentrations of SVOCs are reported for GSP-SB-120-18-20 (18–20 feet below grade). This boring is in the north-central portion of REC #11, northwest of the former Critical Test Building. As shown in Table 4-5, several SVOCs were frequently detected in the REC #11 soil samples. Concentrations of benzo(a)pyrene exceed the non-residential criterion only in 13 of 54 REC #11 soil samples, and exceed both the residential and non-residential criteria in 14 of the REC #11 soil samples.

The BaPEq values (calculated based on positive detects only) in 17 of the 2011 surface soil samples at REC #11 exceed the BaPEq screening benchmark of 140 micrograms per kilogram (µg/kg), as shown in Figure 4-7. The BaPEq values for six of the subsurface soil boring samples in REC #11 exceed the BaPEq screening benchmark, as shown in Figures 4-8 and 4-9. The BaPEq values for the remaining REC #11 samples are less than the screening benchmark for BaPEq.

The PCB Aroclor-1242 was detected in two soil samples in the REC #11 area at concentrations less than the comparison criteria (GSP-SB-120-6-8 at 21 J µg/kg, and GSP-SB-121-6-8 at 130 µg/kg). Aroclor-1260 was detected in 16 of the REC #11 soil boring samples. Aroclor-1260 concentrations, ranging from 1700–3,400 µg/kg, exceed both the residential and non-residential standards in four samples (GSP-SB-119-6-8, GSP-SB-120-0-2, GSP-SB-121-0-3, and GSP-SB-122-0-2), and exceed only the non-residential standard in two samples (GSP-SB-118-0-2 at 1200 µg/kg and GSP-SB-123-0-2 at 640 µg/kg). Borings GSP-SB-118 and GSP-SB-119 are in the footprint of the former Critical Test Building, and GSP-SB-120 is in the north-central portion of REC #11, northwest of the former Critical Test Building. Soil borings GSP-SB-121, GSP-SB-122, and GSP-SB-123 are immediately south–southwest of this area.

Concentrations of four metals (arsenic, total chromium, thallium, and vanadium) exceed soil standards in one or more samples. Arsenic exceeds residential and non-residential standards in 25 of the 54 REC #11 soil boring samples. Of these 25 arsenic results, eight samples also had arsenic concentrations exceeding the eastern Maryland ATC of 3.6 mg/kg: GSP-SB-111-6-8, GSP-SB-113-0-2, GSP-SB-119-0-2, GSP-SB-121-0-3, GSP-SB-124-0-2, GSP-SB-125-0-2, GSP-SB-126-0-2, and GSP-SB-128-0-2. However, the detected concentrations in all these samples, except for GSP-SB-111-6-8 (i.e., all of the surface soil samples listed), are similar to the eastern Maryland ATC for arsenic, and thus are not considered the result of site-related activities. Therefore, only one arsenic exceedance appears to represent possible site-related impacts: sample GSP-SB-111-6-8, collected east of the REC #11 area, at a concentration of 52 mg/kg.

Other metals exceeding non-residential criteria in REC #11 soil boring samples include chromium (two samples), thallium (four samples), and vanadium (37 samples). Of the 37 vanadium results exceeding the residential standard, 33 are less than the eastern Maryland ATC, and three slightly exceed but are similar to the ATC of 30 mg/kg for vanadium. Only one vanadium result exceeds the residential and non-residential standards as well as the ATC (in sample GSP-SB-111-6-8, the same sample in which arsenic impacts were observed). The concentrations of other metals in the REC #11 soil boring samples are less than their applicable comparison criteria.

4.4 GROUNDWATER RESULTS

Groundwater samples were collected for laboratory analyses in June 2011 from the following monitoring wells:

- eight temporary well points previously installed (2010) at GSP: SB/WP-50; SB/WP-54; SB/WP-61; SB/WP-66; SB/WP-71; SB/WP-83; SB/WP-84; and SB/WP-89
- eight newly installed wells: (GSP-MW-01 through GSP-MW-08)

Groundwater samples were submitted for the following analyses:

- VOCs by SW846 Method 8260C
- SVOCs and 1,4-dioxane by SW846 Method 8270D
- TPH-GRO and TPH-DRO by SW846 Method 8015
- total and dissolved Priority Pollutant metals by SW846 Method 6010C/7471A
- perchlorate by USEPA Method 314
- hexavalent chromium by USEPA Method 218.6

Table 4-6 shows the statistical summary of contaminants detected, and Table 4-7 highlights analyte concentrations that exceed the Maryland groundwater standards for the temporary well point samples. Table 4-8 shows the statistical summary of contaminants detected, and Table 4-9 highlights analyte concentrations that exceed Maryland groundwater standards for samples collected from the newly installed monitoring wells. The groundwater-sampling results summarized below are grouped by the two main investigation areas: (1) RECs #8, #9, and #10, and (2) REC #11. Figure 4-10 shows groundwater results for RECs #8, #9 and #10, and Figure 4-11 shows groundwater results for REC #11. Groundwater concentrations are reported in micrograms per liter (µg/L).

4.4.1 RECs #8, #9 and #10 Groundwater Results

Groundwater samples were collected in the REC 8 area from two existing temporary well points: GSP-SB/WP-50 and GSP-SB/WP-54. All analytes detected in the REC #8 area groundwater samples were below MDE groundwater criteria, except for three total (unfiltered) metals: arsenic, lead, and vanadium in GSP-SB/WP-50. The results for these three metals in the filtered

(dissolved) sample from this location are below MDE groundwater criteria, indicating the elevated concentrations in the unfiltered sample may be attributable to sample turbidity (i.e., suspended solids).

In the REC #9 area, groundwater samples were collected from one previously installed well point (GSP-SB/WP-61) and two new monitoring wells (GSP-MW-07 and GSP-MW-08). Five VOCs were detected in GSP-MW-07 and GSP-MW-08, along with TPH-GRO and several metals. TCE and TPH-GRO in GSP-MW-07 exceed their respective MDE criteria. TPH-DRO was also detected in GSP-MW-07 at a concentration exceeding the MDE standard; however, the DRO result was "B" qualified, indicating DRO was present in the laboratory blank.

None of the other organic analytes were detected in GSP-MW-07 or GSP-MW-08 at concentrations exceeding the MDE standards. None of the metal concentrations detected in these two REC #9 wells exceeded MDE criteria. One metal (vanadium) was detected in the unfiltered sample from GSP-SB/WP-61 at a concentration greater than its MDE standard; however, the vanadium concentration in the filtered sample from this location is below the criterion.

At REC #10, groundwater samples were collected from two temporary well points (GSP-SB/WP-66 and GSP-SB/WP-71) and from two newly installed monitoring wells (GSP-MW-05 and GSP-MW-06). The analytical results from GSP-SB/WP-66 and GSP-SB/WP-71 indicate concentrations of total and dissolved vanadium exceeding the MDE criterion. Other analytes detected in these temporary well points were at concentrations below MDE criteria. Metal concentrations in GSP-MW-05 and GSP-MW-06 are less than MDE criteria. However, the DRO concentrations detected in GSP-MW-05 and GSP-MW-06 (1,400 and 1,600 µg/L, respectively) exceed the MDE groundwater standard of 47 µg/L.

4.4.2 REC #11 Groundwater Results

In the REC #11 area, four monitoring wells (GSP-MW-01 through GSP-MW-04) and three temporary well points (GSP-SB/WP-83, GSP-SB/WP-84, and GSP-SB/WP-89) were sampled. TCE was detected at concentrations exceeding the MDE standard of 5 µg/L at the following three locations: GSP-MW-01 (12 µg/L), GSP-MW-04 (6 µg/L), and GSP-SB/WP89 (25 µg/L). The TPH-DRO concentrations detected in GSP-MW-01, GSP-MW-02, and GSP-MW-03 exceed

the MDE criterion. TPH-GRO concentrations in GSP-MW-01 and GSP-SB/WP-89 exceed the MDE standard, but are "B" qualified, indicating GRO was present in the laboratory blank.

Concentrations of other organic analytes in the REC #11 groundwater samples are below MDE screening criteria. Analytical results from GSP-SB/WP-84 indicate total and dissolved nickel and vanadium concentrations both exceed their MDE criteria. In GSP-MW-01, total nickel concentrations exceed the MDE criterion in the unfiltered sample, but dissolved nickel concentrations are below MDE criteria in the filtered sample. Conversely, in the filtered sample from GSP-MW-03, the dissolved nickel concentration exceeds the MDE criterion, but the total nickel result for the unfiltered sample is less than the criterion. Total (unfiltered) vanadium concentrations in GSP-SB/WP-89 and GSP-MW-03 are greater than the MDE criterion, whereas dissolved (filtered) vanadium results in both samples are less than the MDE standard. Similarly, total (unfiltered) arsenic concentrations in GSP-SB/WP-83 and GSP-MW-03 are greater than the MDE criterion, whereas dissolved (filtered) arsenic results in both samples are less than the MDE standard.

MDE - Maryland Department of Environment - June 2008

-- Not detected.

B - Blank contaminant.

J - Positive result is considered estimated as a result of technical noncompliance.

L - Positive result is considered to be biased low as a result of technical noncompliance.

K - Positive result is considered to be biased high as a result of technical noncompliance.

NA - Not Analyzed.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

Gray shaded values exceed MDE residential screening criteria.

Black shaded values exceed MDE residential and non-residential screening criteria.

MDE - Maryland Department of Environment - June 2008

-- Not detected.

B - Blank contaminant.

J - Positive result is considered estimated as a result of technical noncompliance.

L - Positive result is considered to be biased low as a result of technical noncompliance.

K - Positive result is considered to be biased high as a result of technical noncompliance.

NA - Not Analyzed.

ug/kg - microgram per kilogram

mg/kg - milligram per kilogram

Gray shaded values exceed MDE residential screening criteria.

Black shaded values exceed MDE residential and non-redisential screening criteria.

MDE - Maryland Department of the Environment, June 2008.

-- - Not detected at listed detection limit.

B - Laboratory blank contamination.

J - Positive result is considered estimated as a result of technical noncompliance.

ug/l - micrograms per liter.

Shaded values exceed MDE groundwater criteria.

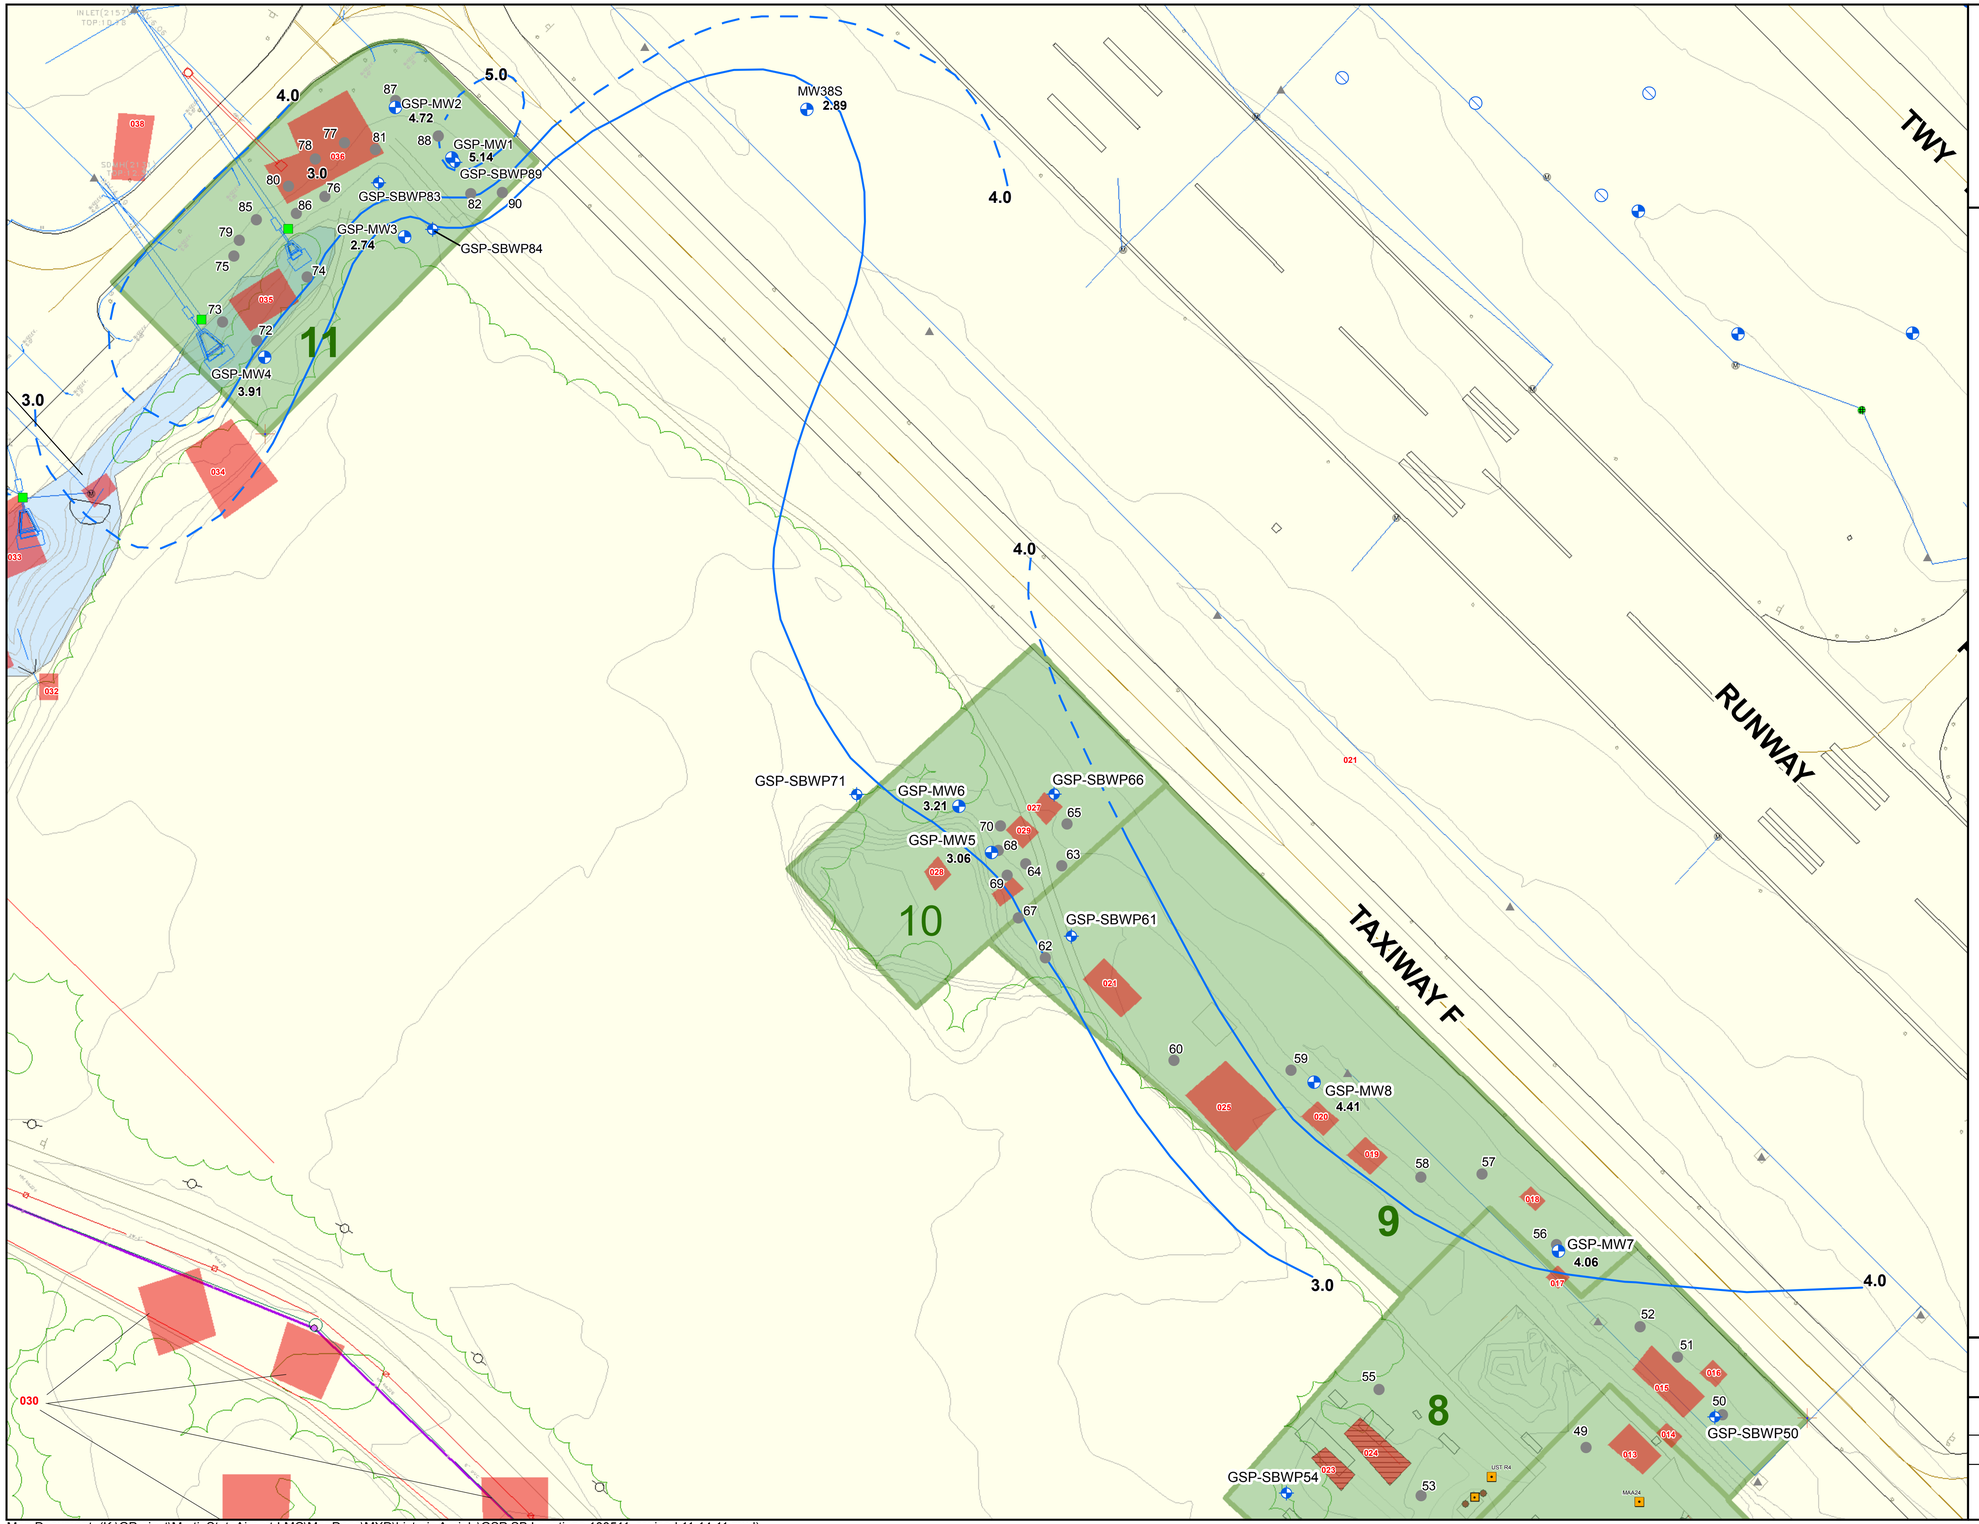
MDE - Maryland Department of the Environment, June 2008.

-- - Not detected at listed detection limit.

B - Laboratory blank contamination.



J - Positive result is considered estimated as a result of technical noncompliance.

ug/l - micrograms per liter.

Shaded values exceed MDE groundwater criteria.

Section 5
Human Health Risk Assessment

The baseline human health risk assessment (HHRA) evaluates whether detected concentrations of chemicals in the Greater Strawberry Point (GSP) study area pose a significant health risk to potential human receptors under current and/or future land uses. Potential risks to human receptors are estimated on the assumption that no actions are taken to control contaminant releases. Primary guidance sources used to prepare this HHRA include the Maryland Department of the Environment (MDE) *Cleanup Standards for Soil and Groundwater* (State of Maryland, 2008) and *Voluntary Cleanup Program Guidance* (State of Maryland, 2006). The following current guidance and reports published by the U.S. Environmental Protection Agency (USEPA) and USEPA Region 3 were also considered in preparing the HHRA:

- *Soil Screening Guidance: Technical Background Document* (USEPA, 1996a)
- *Supplemental Guidance for Developing Soil-Screening Levels for Superfund Sites* (USEPA, 2002a)
- *Exposure Factors Handbook*. Office of Research and Development, National Center for Environmental Assessment, Washington, D.C. EPA/600/P-95/002Fa (USEPA, 1997a)
- *Exposure Factors Handbook: 2011 Edition*. National Center for Environmental Assessment, Washington, DC; EPA/600/R-09/052F (USEPA, 2011a)
- *Human Health Evaluation Manual, Supplemental Guidance: Standard Default Exposure-Factors*. Office of Solid Waste Emergency Response (OSWER) Directive 9285.6 03, OSWER, Washington, D.C. (USEPA, 1991)
- Distribution of *Preliminary Review Draft: Superfund's Standard Default Exposure-Factors for Central-Tendency and Reasonable Maximum Exposure*. OSWER, Washington, D.C. (USEPA, 1993a)
- *Calculating Upper Confidence-Limits for Exposure-Point Concentrations at Hazardous Waste Sites*. Office of Emergency and Remedial Response, Washington, D.C. OSWER 9285.6-10 (USEPA, 2002b)

- *Risk Assessment Guidance for Superfund (RAGS), Volume I: Human Health Evaluation Manual (Part A)* (USEPA, 1989)

- *Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment), Final*. Office of Superfund Remediation and Technology Innovation, Washington, D.C. 20460 EPA/540/R/99/005, OSWER 9285.7-02EP; PB99-963312 (USEPA, 2004a)

- *Guidelines for Carcinogen Risk Assessment*. EPA/630/P-03/001B. March 2005 (USEPA, 2005a)

- *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens*. EPA/630/R-03/003F (USEPA, 2005b)

- *Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (Part F, Supplemental Guidance for Inhalation-Risk Assessment), Final*. Office of Superfund Remediation and Technology Innovation, Washington, D.C. 20460 EPA-540-R-070-002, OSWER 9285.7-82 (USEPA, 2009)

- *Updated Dermal-Exposure Guidance* (USEPA Region 3, 2003a)

The risk assessment protocols in the following technical documents, which were prepared for Lockheed Martin Corporation (Lockheed Martin) sites at Martin State Airport (MSA) site as well as for the Middle River Complex (MRC), were also considered:

- *Revised Human Health Risk Assessment, MSA, Middle River, Maryland*. Prepared for Lockheed Martin Corporation (Tetra Tech, Inc. [Tetra Tech], 2006a)

- *Site Characterization Report, Lockheed Martin MRC, 2323 Eastern Boulevard, Middle River, Maryland* (Tetra Tech, 2006b)

- *Remedial Investigation Report, MSA, Middle River, Maryland*. Prepared for Lockheed Martin Corporation (Tetra Tech, 2010)

- *Human Health Risk Assessment for Blocks D, E, F, G, and H Soils, Lockheed Martin MRC, 2323 Eastern Boulevard, Middle River, Maryland*. Prepared for Lockheed Martin Corporation (Tetra Tech, 2011)

The HHRA for GSP Recognized Environmental Conditions (RECs) #9, #10, and #11 is structured and reported according to the guidelines in the *RAGS (Human Health Evaluation Manual, Part D: Standardized Planning, Reporting, and Review of Superfund Risk Assessments* [*RAGS Part D]* [USEPA, 2001]). The HHRA consists of the following six components (see Sections 5.1 through 5.6 for a more complete discussion):

- data evaluation
- toxicity assessment
- uncertainty analysis
- exposure assessment
- risk characterization
- development of remedial goal options

5.1 DATA EVALUATION

The first step of the baseline HHRA, data evaluation, is a medium-specific task that begins with compilation of relevant analytical data and concludes with the selection of chemicals of potential concern (COPC) to be evaluated in subsequent steps of the assessment. First, the data available for the relevant study area(s) are reviewed in terms of data quality; only validated data are used in the assessment. Environmental samples selected for HHRA are summarized in the tables in Appendix J. Second, a medium-specific list of COPC (used to quantitatively and/or qualitatively determine potential human health risks) was selected based on a toxicity screen (i.e., a comparison of site contaminant concentrations to conservative toxicity-screening values).

5.1.1 Data Usability

Validated data collected during the following environmental investigations were used to assess risks to potential human receptors:

- Round 1 of Phase II investigation (April–May 2010)
- Round 2 of Phase II investigation (May–June 2011)

Samples used were those collected from RECs #9, #10, and #11 during these investigation rounds. As indicated earlier, only one soil sample from REC #8 (surface soil sample SB-91) was included in the risk assessment because its location was considered relevant to and at the boundary of REC #9. (COPC were detected infrequently in REC #8, and at concentrations below the relevant cleanup criteria in borings and test pits; therefore, the REC #8 area was not considered in the risk assessment.) Environmental samples specifically evaluated in the HHRA are listed in Tables 5-1 through 5-4 (and Appendix J):

- *Table 5-1*: Soil samples collected primarily in the 0–2 feet below grade interval for each of the three RECs. Samples collected from depths of 1–3 feet and 0–3 feet were included as well. These samples are considered surface soil samples for the purposes of the HHRA.

- *Table 5-2*: Soil samples collected at depths greater than two feet below grade but less than or equal to 15 feet below grade are considered shallow-subsurface soil samples for the purposes of the HHRA. The depth to groundwater in the study area ranges from three to 15 feet below grade. Therefore, data for these samples are representative of conditions in the unsaturated (vadose) zone and upper saturated-zone soils. It is assumed that direct contact with the deeper saturated-zone soils (i.e., soil samples greater than 15 feet below grade; see Table 5-3) is very unlikely; therefore, this HHRA does not quantitatively evaluate direct-contact exposure to deeper saturated-zone soils.

- *Table 5-3*: Soil samples collected at depths greater than 15 feet below grade are considered deep subsurface-soil samples for the purposes of the HHRA. It is assumed that direct contact with the deeper saturated-zone soils (i.e., soil samples greater than 15 feet below grade) is very unlikely; therefore, this HHRA does not quantitatively evaluate direct-contact exposure to deeper saturated-zone soils. The uncertainty analysis (see Section 5.5) presents a qualitative evaluation of contaminants detected in saturated-zone soils.

- *Table 5-4*: Samples collected in 2010 and 2011 from temporary groundwater monitoring wells and in 2011 from permanent groundwater monitoring wells. The screened intervals of all monitoring wells evaluated in the HHRA are listed in Table 5-4.

Fixed-base analytical results (i.e., results from a fixed-base laboratory and not from field screening/testing) from field investigations for target analytes were used in the quantitative risk evaluation. Field measurements and data regarded as rejected (i.e., that were qualified as "R" during data validation) were not used in the quantitative risk assessment.

5.1.2 Selection of Chemicals of Potential Concern

Selecting COPC is a qualitative screening process to limit the number of chemicals quantitatively evaluated in the baseline HHRA to those site-related constituents that dominate overall potential risks. Screening by risk-based concentrations focuses the risk assessment on meaningful chemicals and exposure routes. In general, a chemical was selected as a COPC in the HHRA and retained for further quantitative risk evaluation if its maximum detected concentration in a soil or groundwater data-set exceeded the lowest risk-based screening concentration. Chemicals eliminated from further evaluation are assumed to present minimal risks to potential human receptors. Tables summarizing the selection of COPC are included in the risk assessment and referenced in the following sections.

5.1.2.1 Derivation of Screening Criteria

The primary COPC screening criteria for the study area soils were derived from MDE's *Cleanup Levels for Soil and Groundwater* (State of Maryland, 2008) and USEPA Regional Screening Levels (RSLs) developed by the U.S. Department of Energy's Oak Ridge National Laboratory (ORNL) on behalf of USEPA (USEPA, 2011b). The more conservative of these values were used to select COPC. These risk-based concentrations are based on exposure pathways for which generally accepted methods, models, and assumptions have been developed (i.e., ingestion, dermal contact, inhalation) for specific land uses (residential, industrial). They do not consider effects on groundwater or ecological receptors. The COPC screening levels used in the HHRA to evaluate soil and groundwater data are listed in Tables 5-5 and 5-6, respectively, and defined in the following narrative.

Screening levels for soil—Screening levels to select COPC for direct human-contact and -inhalation exposures to surface and subsurface soil are based on the following criteria:

- *Interim Final Guidance from the State of Maryland, Department of the Environment, Cleanup Standards for Soil and Groundwater* (State of Maryland, 2008)
- *Regional Screening-Levels for Residential Soil* (USEPA, 2011b)

COPC screening levels (based on MDE cleanup standards derived from risk-based concentrations) correspond to a systemic-hazard quotient (HQ) of 0.1 for noncarcinogens, or an incremental lifetime-cancer-risk (ILCR) of 1×10^{-6} (i.e., a one-in-a-million probability) for carcinogens. In contrast, USEPA RSLs are based on an HQ of 1 for noncarcinogens and an ILCR of 1×10^{-6} for carcinogens. As presented in Table 5-5, USEPA RSLs for noncarcinogens are based on an HQ of 1, so COPC screening-levels based on USEPA RSLs were adjusted to correspond to a systemic HQ of 0.1 (for noncarcinogens), to account for the potential cumulative effects of several chemicals affecting the same target organ or producing the same adverse (noncarcinogenic) effect. Soil-screening levels derived from both of these sources were used for direct-contact COPC selection. As noted above, the more conservative of the available values were used for COPC selection.

Maximum chemical concentrations in soil were also compared to MDE cleanup levels for groundwater protection (as published in State of Maryland, 2008), as well as to federal SSLs for

groundwater protection, which are designed to protect groundwater at most sites (as published in the USEPA RSL table). These groundwater-protection SSLs allow an initial qualitative evaluation of the potential for chemical migration from soil to groundwater. MDE cleanup levels for groundwater protection are based on a dilution attenuation-factor (DAF) of 20, whereas federal SSLs for groundwater protection are based on a DAF of 1. Chemicals with concentrations exceeding MDE groundwater-protection criteria or the SSLs' criteria may potentially migrate from soil to groundwater in sufficient quantities to pose groundwater quality problems. Chemicals detected at concentrations exceeding MDE groundwater protection criteria or the federal SSL for groundwater protection, but at concentrations less than COPC screening levels for direct-contact risk, will not be evaluated quantitatively in the HHRA. However, these chemicals will be further evaluated qualitatively using the approach presented in Section 5.4.3.

Screening levels for groundwater—To be conservative, groundwater at the site was evaluated assuming potential residential groundwater use. COPC screening levels for groundwater are based on MDE cleanup standards for groundwater (State of Maryland, 2008), USEPA RSLs for tap water (USEPA, 2011b), groundwater screening-levels for vapor intrusion *(GSL_{vapor})* calculated using methodology from USEPA *Generic Screening Levels for Groundwater for Evaluating Vapor Intrusion to Indoor Air* (USEPA, 2002c), and the primary federal Safe Drinking Water Act (SDWA) maximum contaminant levels (MCLs) (USEPA, 2011c).

The MDE cleanup standards for groundwater (derived from risk-based concentrations) correspond to a systemic HQ of 0.1 for noncarcinogens, or an ILCR of 1×10^{-6} for carcinogens. The adjusted COPC screening levels (based on USEPA RSLs for tap water) correspond to a systemic HQ of 0.1 for noncarcinogens, or an ILCR of 1×10^{-6} for carcinogens. Table 5-6 presents the RSLs based on an HQ of 1; however, the COPC screening values have been adjusted and are based on an HQ of 0.1.

The GSL_{vapor} guidelines were originally published in Table 2C of USEPA's *Evaluating Vapor-Intrusion into Indoor Air* (EPA530-F-02-052 [USEPA, 2002c]), and in updates to that table. The $GSLs_{vapor}$ were derived in 2002, and the toxicity criteria for a number of chemicals have changed since then. Consequently, new criteria were derived using the methodology in Appendix C of the guidance and the residential air USEPA RSLs in the November 2011 RSL table. As presented in Table 5-6, these values correspond to a target cancer-risk level of 1×10^{-6},

or an HQ of 1 for carcinogens and noncarcinogens, respectively. The $GSLs_{vapor}$ values were derived to identify chemical concentrations in groundwater that may adversely affect the indoor air quality of a building overlying subsurface volatile organic compound (VOC) contamination. The $GSLs_{vapor}$ value assumes a subsurface attenuation factor of 0.001 from groundwater concentrations to indoor air concentrations. The COPC screening levels for noncarcinogens are adjusted to be based on an HQ of 0.1.

Federal SDWA MCLs for public drinking-water supplies are enforceable standards designed to protect human health, promulgated under the federal SDWA. Primary MCLs are based on laboratory or epidemiological studies and apply to public water systems. A public water system is defined as a system providing water to the public for human consumption that either has at least 15 service connections, or regularly serves an average of 25 individuals daily, for at least 60 days per year.

Primary MCLs are designed to prevent adverse human health effects, but also reflect the technical feasibility of removing a contaminant from water. Primary (i.e., health based) and secondary (i.e., aesthetic based) MCLs are promulgated under the SDWA. Secondary MCLs are non-enforceable standards and therefore are not used in COPC selection or included in the COPC selection tables.

Screening levels for lead—Guidance from the USEPA Office of Prevention, Pesticides, and Toxic Substances (OPPTS) and Office of Solid Waste and Emergency Response (OSWER) recommends 400 milligrams per kilogram (mg/kg) as the screening level for lead impacted soil in a residential setting where children are frequently present (USEPA, 1994). To be conservative, 400 mg/kg was used as the screening level to select COPC for soil. However, guidance from the USEPA Technical Review Workgroup for Lead indicates that "a reasonable screening level for soil lead at commercial/industrial (i.e., non-residential) sites is 800 mg/kg" for a typical non-contact-intensive worker (2010a); 800 mg/kg is also the current USEPA RSL for soils (November 2011), assuming an industrial land use scenario. The SDWA action level of 15 micrograms per liter (µg/L) was used as the screening level for lead in groundwater.

5.1.2.2 Decision Rules for Establishing Chemicals of Potential Concern

The following decision rules were used to select COPC for the GSP soils and groundwater evaluated:

- A chemical detected in soil or groundwater was selected as a COPC for the HHRA if the maximum detected chemical concentration exceeded its relevant screening level for soils or groundwater. Surrogate COPC screening levels were used for some chemicals. For example, risk-based COPC screening levels are not currently available from USEPA for some chemicals that have been detected in study area soils (e.g., 1,3-dichlorobenzene, acenaphthylene, benzo[g,h,i]perylene, phenanthrene) due to the lack of toxicity criteria. For purposes of COPC selection, 1,4-dichlorobenzene was used as a surrogate for 1,3-dichlorobenzene; acenaphthene was used as a surrogate for acenaphthylene; pyrene was used as a surrogate for both benzo(g,h,i)perylene and phenanthrene. For groundwater, trans-1,2-dichloroethene was used as a surrogate for cis-1,2-dichloroethene for vapor-intrusion COPC-selection.

- Some chemicals (e.g., naphthalene) are reported in both the VOC and semivolatile organic compound (SVOC) fractions, and naphthalene results in both fractions were evaluated in COPC selection. See Section 5.5.1 for a discussion of uncertainty related to naphthalene results used in this HHRA.

- Per current USEPA guidance (USEPA, 1993b), cancer-risk estimates for benzo(a)pyrene and six other polycyclic aromatic-hydrocarbons (PAHs) (benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, and indeno[1,2,3-cd]pyrene) were calculated in terms of benzo(a)pyrene equivalent concentrations (BaPEq) that are calculated using USEPA-recommended toxicity-equivalency factors (TEFs). TEFs are based on the potency of each of these PAH compounds relative to that of benzo(a)pyrene. TEFs are used to convert each individual PAH concentration into an equivalent concentration of benzo(a)pyrene. The sum of these equivalent concentrations for the six other PAHs (mentioned above) and benzo(a)pyrene is the BaPEq concentration. Exposure-point concentrations (EPC) for these PAHs were derived using benzo(a)pyrene-equivalent concentrations calculated for each sample.

  BaPEq were calculated two ways: (1) the BaPEq-½-non-detect value was calculated using one-half of the detection limit to represent non-detect results in the calculation, and (2) the BaPEq-positive-results value was calculated using a value of zero to represent non-detect PAH results. In either BaPEq calculation, if none of the PAHs were detected in a sample, then the sample quantitation-limit for benzo(a)pyrene was used as the equivalent concentration for that sample. Values for both BaPEq calculations are presented in the COPC-selection tables.

  For the data sets evaluated in this HHRA, both values calculated for BaPEq are similar; therefore, the BaPEq-½-non-detect values were used in the risk assessment, since these values are slightly more conservative due to the incorporation of non-detects. Using one-half of the detection limit for non-detects recognizes that the concentration of a PAH in

a specific sample may be greater than zero even though the result is considered non-detected (i.e., the PAH may be present at a concentration between zero and the sample quantitation limit). The fact that the BaPEq results for both the ½-non-detect and positive-results-only calculations are similar indicates that elevated detection-limits are not resulting in biased-high BaPEq results for the ½-non-detect calculation.

- For polychlorinated biphenyls (PCBs), individual Aroclors were compared to screening criteria for individual Aroclor-compounds. Total Aroclor-concentrations were determined on a sample-specific basis by summing the individual Aroclor-concentrations detected. If all Aroclor-results in a given sample were non-detected, the total Aroclor-result was reported as "0 U" in the database. Total Aroclor-results are presented in the COPC selection tables where applicable.

- Only total chromium data were available for the samples evaluated in this HHRA; no hexavalent chromium data are included in the data sets evaluated. To be conservative, screening levels for hexavalent chromium, the more toxic form of chromium, were used to evaluate total chromium instead of trivalent-chromium screening levels. Evaluation of chromium is further discussed in Sections 5.3 and 5.4.

5.1.3 COPC Selected for the HHRA

COPC for GSP were selected for surface and subsurface soil and groundwater using the COPC screening levels described in the preceding narrative. COPC selection was based on samples from all RECs (i.e., RECs #9, #10, and #11) combined to produce a list of "global" COPC. Global COPC were further evaluated on an exposure-unit (EU)-specific basis as part of the quantitative risk assessment, based on whether the COPC were detected in a specific EU. (An EU is defined in the exposure assessment; see Section 5.3). Thus, if a global COPC was not detected in a particular EU, it was not evaluated in that EU. This method was used instead of assigning surrogate concentration values (e.g., sample quantitation-limits [SQLs]) to global COPC that were never detected in that EU.

A discussion of the chemicals identified as global COPC and the rationale for their selection as global COPC is provided in the following subsections. Global COPC-selection tables for surface and subsurface soil are presented in Tables 5-7 through 5-10. Global COPC selection for the deep subsurface soils (not evaluated quantitatively in the HHRA) is presented in Table 5-11. Global COPC selection for groundwater-associated direct contact and vapor intrusion are presented in Tables 5-12 and 5-13, respectively. Chemicals retained as global COPC for GSP are presented in Table 5-14. The *RAGS Part D* tables for COPC selection are in Appendix J.

5.1.3.1 Surface Soil (0–2 Feet below Grade)

Twenty-one VOCs, 25 SVOCs (including PAHs), one polychlorinated biphenyl (PCB), 19 metals, and petroleum-hydrocarbon compounds were detected in the surface soil samples listed in Table 5-1. A comparison of the maximum-detected surface soil concentrations to screening levels (based on MDE cleanup levels and USEPA RSLs) is in Table 5-7. The following chemicals were detected in surface soils at maximum concentrations exceeding the direct-contact risk-based COPC screening-levels and were retained as global COPC for surface soil:

- *SVOCs:* benzo(a)pyrene equivalents, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, and n-nitroso-di-n-propylamine
- *PCBs:* Aroclor-1260 and total Aroclor
- *Metals:* arsenic, chromium, cobalt, iron, manganese, thallium, and vanadium
- *Petroleum hydrocarbons:* diesel-range organics (DRO)

No COPC screening levels based on MDE cleanup standards or USEPA RSLs are available for tertiary-butyl alcohol. Chemicals lacking screening criteria are qualitatively evaluated in the uncertainty analysis (see Section 5.5). Total chromium was selected as a COPC based on hexavalent chromium screening-criteria; chromium would not be a COPC if trivalent screening criteria had been used for COPC selection. Uncertainty associated with the assessment of chromium toxicity is discussed further in Section 5.5.

A comparison of the maximum-detected surface soil concentrations to USEPA SSLs for chemical migration from soil to groundwater is in Table 5-8. The following chemicals were detected in surface soil at maximum concentrations exceeding the COPC screening-levels for migration from soil to groundwater and were retained as global COPC for surface soil:

- *VOCs:* 1,2,4-trichlorobenzene, 1,3-dichlorobenzene, benzene, methylene chloride, naphthalene, and trichloroethene
- *SVOCs:* 2-methylnaphthalene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, bis(2-ethylhexyl)phthalate, butyl benzyl phthalate, carbazole, chrysene, dibenzo(a,h)anthracene, dibenzofuran, indeno(1,2,3-cd)pyrene, naphthalene, and n-nitroso-di-n-propylamine, phenanthrene, and pyrene

- *PCBs:* Aroclor-1260 and total Aroclor
- *Metals:* antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, selenium, and thallium

Total chromium was selected as a COPC for migration from soil to groundwater based on hexavalent chromium screening-criteria. Chromium would not be a COPC for migration from soil to groundwater if trivalent chromium screening criteria had been used. The potential for chemical migration from soils to groundwater is more fully evaluated in Section 5.4.

5.1.3.2 Shallow Subsurface-Soil (Greater than 2–15 Feet below Grade)

Twenty-two VOCs, 24 SVOCs (including PAHs), two PCBs, 19 metals, and petroleum hydrocarbons were detected in the shallow subsurface soil samples listed in Table 5-2. Table 5-9 compares the maximum-detected subsurface soil concentrations to screening levels (based on MDE cleanup levels and USEPA RSLs). The following chemicals were detected in shallow subsurface soils at maximum concentrations exceeding the direct-contact risk-based COPC screening-levels and were retained as global COPC for shallow subsurface soil:

- *VOCs:* naphthalene
- *PAHs:* benzo(a)pyrene equivalents, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene
- *PCBs:* Aroclor-1260 and total Aroclor
- *Metals:* arsenic, chromium, cobalt, iron, manganese, thallium, and vanadium
- *Petroleum hydrocarbons:* DRO

No COPC screening levels based on MDE cleanup standards or USEPA RSLs are available for 4-isopropyltoluene and sec-butylbenzene. Chemicals lacking screening criteria are qualitatively evaluated in the uncertainty analysis (see Section 5.5). Total chromium was selected as a COPC based on hexavalent chromium screening criteria; chromium would not be a COPC if trivalent screening criteria had been used for COPC selection. Uncertainty associated with the assessment of chromium toxicity is further discussed in Section 5.5.

Table 5-10 compares the maximum-detected shallow subsurface soil concentrations to MDE cleanup goals for groundwater protection and to USEPA SSLs for chemical migration from soil to

groundwater. The following chemicals were detected in subsurface soil at maximum concentrations exceeding COPC screening-levels for migration from soil to groundwater and were retained as global COPC for subsurface soil:

- *VOCs:* 1,2,3-trimethylbenzene, 1,2,4-trimethylbenzene, benzene, ethylbenzene, m+p-xylenes, methylene chloride, naphthalene, o-xylene, total xylenes, trichloroethene, and vinyl chloride
- *SVOCs:* 1,1-biphenyl, 2-methylnaphthalene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, bis(2-ethylhexyl)phthalate, carbazole, chrysene, dibenzo(a,h)anthracene, dibenzofuran, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, and pyrene
- *PCBs:* Aroclor-1242, Aroclor-1260, and total Aroclor
- *Metals:* antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, thallium, and vanadium

Total chromium was selected as a COPC for migration from soil to groundwater based on hexavalent chromium screening-criteria. Chromium would not be a COPC for migration from soil to groundwater if trivalent chromium screening criteria had been used. Section 5.4 presents a more refined evaluation of the potential for chemicals to migrate from soils to groundwater.

5.1.3.3 Deep Subsurface-Soil (Greater than 15 Feet below Grade)

This HHRA for GSP assumes that direct human contact with deep subsurface soils is very unlikely. Therefore, risk estimates are not presented for direct contact with this environmental medium. However, to be complete, Table 5-11 compares the maximum-detected concentrations to the direct contact and inhalation COPC-selection criteria for soils. Maximum detected concentrations are not compared to USEPA SSLs for groundwater protection because the deep subsurface soils are in the saturated-soil zone. Any remediation of COPC in this zone would be based on contamination actually observed in groundwater, and not on contamination detected in deep, saturated soils.

Twenty-three VOCs, 22 SVOCs (including PAHs), 19 metals, and petroleum hydrocarbons were detected in the deep subsurface soils. The following chemicals were detected at concentrations exceeding direct-contact COPC screening-levels:

- *VOCs:* trichloroethene

- *PAHs:* benzo(a)pyrene equivalents, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene
- *Metals:* arsenic, chromium, cobalt, copper, thallium, and vanadium
- *Petroleum hydrocarbons:* DRO

The uncertainty analysis (Section 5.5) contains a more detailed qualitative evaluation of the global COPC selected for deep subsurface soil. Total chromium was selected as a COPC based on hexavalent chromium screening criteria; chromium would not be a COPC if trivalent screening criteria had been used for COPC selection. Uncertainty associated with the assessment of chromium toxicity is further discussed in Section 5.5.

5.1.3.4 Groundwater

Eighteen VOCs, five SVOCs, 18 metals, and petroleum hydrocarbons were detected in the groundwater samples listed in Table 5-4. Table 5-12 compares the maximum-detected groundwater concentrations to screening levels based on MDE cleanup standards, USEPA RSLs for tap water, and USEPA MCLs. The following chemicals were detected at concentrations exceeding direct-contact COPC screening-levels:

- *VOCs:* benzene, carbon tetrachloride, chloroform, cis-1,2-dichloroethene, trichloroethene, and vinyl chloride
- *SVOCs:* 4-methylphenol and bis(2-ethylhexyl)phthalate
- *Dissolved metals:* arsenic, beryllium, cadmium, chromium, cobalt, iron, manganese, nickel, thallium, vanadium, and zinc
- *Total metals:* arsenic, beryllium, cadmium, chromium, cobalt, iron, manganese, nickel, thallium, vanadium, and zinc
- *Petroleum hydrocarbons:* DRO and gasoline-range organics (GRO)

No COPC screening levels based on MDE cleanup standards or USEPA RSLs are available for tertiary-butyl alcohol. Chemicals lacking screening criteria are qualitatively evaluated in the uncertainty analysis (see Section 5.5). Total chromium was selected as a COPC based on hexavalent chromium screening criteria; chromium would not be a COPC if trivalent screening criteria had been used for COPC selection. Uncertainty associated with the assessment of chromium toxicity is further discussed in Section 5.5.

Table 5-13 compares the maximum detected groundwater concentrations to vapor-intrusion screening levels calculated using methodology from the *Draft Guidance for Evaluating the Vapor-Intrusion to Indoor-Air Pathway from Groundwater and Soils* (USEPA, 2002c). The following chemicals were detected at concentrations exceeding vapor-intrusion COPC screening-levels:

- *VOCs:* benzene, carbon tetrachloride, chloroform, trichloroethene, and vinyl chloride

These chemicals were also selected as direct-contact COPC for groundwater. Chemicals exceeding the vapor-intrusion COPC screening-levels are further evaluated in Section 5.4.

5.1.3.5 Summary of COPC Selection for the HHRA

Table 5-14 summarizes the chemicals retained as global COPC for surface and subsurface soils and groundwater at GSP. *RAGS Part D* tables for COPC selection are in Appendix J.

5.2 EXPOSURE ASSESSMENT METHODOLOGY

The exposure assessment component of an HHRA defines and evaluates, either quantitatively or qualitatively, the type and magnitude of human exposure to the chemicals at or migrating from a site. It depicts the site's physical setting, identifies potentially exposed populations and applicable exposure pathways, calculates concentrations of COPC to which receptors might be exposed, and estimates chemical intakes under the identified exposure scenarios. Actual or potential exposures at a site depend on the most likely pathways of contaminant release and transport, as well as on patterns of human activity. A complete exposure pathway has four components: a *source* of chemicals that can be released to the environment, a *contaminant-transport route* through an environmental medium, an *exposure* or *contact point* for a human receptor, and an *exposure route*.

5.2.1 Conceptual Site Model

The HHRA includes a conceptual site-model (CSM) that identifies the exposure pathways by which human receptors may come in contact with study area soils. The CSM depicts the relationships among the following elements of a *complete* exposure pathway (i.e., a pathway that potentially results in human exposure and is evaluated [qualitatively or quantitatively] in an HHRA):

- site sources of contamination
- contaminant-release mechanisms and transport/migration pathways
- exposure routes
- potential receptors

These CSM elements establish the manner and degree to which a potential receptor may be exposed to chemicals present at a site. The degree of risk incurred by a potential receptor varies according to the means and duration of exposure, and the specific chemical to which the receptor is exposed. An exposure, however long in duration, does not necessarily result in a regulatorily "unacceptable" health or environmental risk, although risks generally increase with increased frequency and/or duration of exposure.

Section 4.0 discusses the nature and extent of contamination at GSP. The results from this section identified sources of possible contamination, which are discussed in Section 5.2.1.1. Sections 5.2.1.2 and 5.2.1.3 discuss contaminant-release mechanisms and transport and migration pathways. Section 5.2.1.4 and Table 5-15 provide a site-specific summary of potential receptors and exposure pathways to be evaluated for GSP. Table 5-16 summarizes the exposure routes (addressed quantitatively for each human receptor). Figure 5-1 illustrates the CSM for the GSP HHRA.

5.2.1.1 Site Sources of Contamination

The GSP area is in the southwestern portion of MSA and is bounded by the runway to the east and Stansbury Creek to the west. Stansbury Creek is a wide, brackish, tidal tributary of the Chesapeake Bay. Studies at MSA's nearby Dump Road Area indicate that the soil consists of artificial fill composed of heterogeneous layers of sands, silts, and clays. Artificial fill comprises the uppermost 10–20 feet of soil at the site. Scrap metal, wood, brick, etc., in fill have been noted during past environmental investigations (see Section 2). The uppermost native soils beneath the artificial fill are composed of sands, silts, and clays.

The depth to groundwater at the nearby Dump Road Area ranges from approximately three to 18 feet below grade. The surficial aquifer is a combination of the artificial fill and native soil underlying the fill. The native soil is part of the Patapsco Formation. Underlying the Patapsco Formation is the Arundel Formation, which is a thick clay unit that is essentially impermeable. It provides a confining layer between the Patapsco Formation and the Patuxent Formation, which underlies the Arundel Formation. Groundwater in the GSP area is expected to occur at depths of

three to 18 feet, similar to those encountered at the Dump Road Area. Groundwater in the surficial aquifer at the GSP area is also expected to follow the surface topography and flow from the watershed divide near the airport runway area to the southwest and west toward Stansbury Creek, and to the southeast toward Frog Mortar Creek. Surface drainage from GSP discharges via multiple outfalls into Stansbury and Frog Mortar Creeks.

Soil and groundwater data collected from GSP indicate that past activities have released contaminants to the surrounding environment. Contamination at the GSP area may be the result of historical industrial operations centered on naval weapons research, and aircraft maintenance and repair at the site. The results of the previous investigations at GSP, summarized in Sections 2 and 4, have identified three RECs for evaluation in this HHRA:

- *REC #9*—former Propellant Storage, former Acetylene Storage Shed, former Furnace Building, former Hyper-Therm Test facilities, and former Vanguard Tower
- *REC #10*—former Coupon Test Shed and former Block House
- *REC #11*—former Critical Test Building, former Radioisotope Lab, and former Transformer Pad

RECs #9 and #10 are adjacent, and REC #11 is approximately 600 feet northwest of RECs #9 and #10 (see Figure 1-2). As discussed in Section 5.1, detected concentrations of PAHs, one SVOC (n-nitroso-di-n-propylamine), one PCB (Aroclor-1260), metals, and DRO in surface soil exceed their respective direct-contact screening criteria. In subsurface soil, PAHs, Aroclor-1260, metals, and DRO were detected at levels exceeding direct-contact screening criteria. VOCs, SVOCs, metals, DRO and GRO exceed direct-contact screening criteria in groundwater.

5.2.1.2 Potential Contaminant Release Mechanisms and Transport Pathways

Chemicals may migrate within an environmental medium (e.g., soil) or migrate to another environmental medium (e.g., air) once released. This section discusses potential contaminant-release mechanisms and transport pathways. Potential contaminant-release mechanisms and transport pathways are similar for RECs #9, #10, and #11. For example, soil data collected in each EU (RECs #9, #10, and REC #11) indicate that past activities have released contaminants to the surrounding environment.

Contaminants in surface soil could migrate to air through wind erosion or through volatile emissions. Subsurface soil is not currently exposed at the site; however, if future construction were to bring subsurface soil to the surface, contaminants in subsurface soil could be transported into the air through wind erosion or through volatile emissions. Surface soil contaminants could also be transported to surface water bodies (e.g., Stansbury Creek) through overland runoff and erosion.

As noted previously, multiple drainage outfalls in the GSP area drain the GSP study area and surrounding areas. These drainage outfalls discharge to Frog Mortar Creek or Stansbury Creek. Therefore, contaminant transport from soil to surface water could potentially occur. Although subsurface soil is currently not exposed, if future construction were to bring subsurface soil to the surface, contaminants in subsurface soil could then be transported through overland runoff and erosion to surface water bodies. Overland runoff at the study area may not be a significant contaminant transport mechanism due to the generally low-relief site topography. Much of the study area is vegetated, which facilitates infiltration and evapo-transpiration. Infiltration is therefore expected to dominate surface runoff.

Contaminants can migrate from both surface and subsurface soil to groundwater through leaching of chemicals in the soil. At the nearby Dump Road Area, groundwater flows northeast from the airport runway and taxiway toward Frog Mortar Creek. Groundwater in the intermediate surficial-aquifer also flows northeast from the runway and taxiway toward Frog Mortar Creek. Groundwater flows south in the southern portion of the Dump Road Area. Groundwater potentiometric levels in the lower surficial-aquifer are similar to those of the intermediate surficial-aquifer.

Both the intermediate and lower surficial-aquifers have northern components of flow in the northern portion of the site and southern groundwater flow in the southern portion of the site. Groundwater flows from the northwest to the southeast in the deep confined-aquifer. Groundwater in the surficial aquifer at the GSP area is also expected to follow the surface topography and flow from the watershed divide near the airport runway area to the southwest and west toward Stansbury Creek, and to the southeast toward Frog Mortar Creek.

5.2.1.3 Fate and Transport of Primary Site COPC

Brief overviews of the fate and transport of metals, PAHs, PCBs, and VOCs follow:

***Metals*—**The fate and transport of inorganics (metals) are controlled mainly by the mobility of soil particles and their dissolution into water present in the immediate environment. Metals do not undergo the sort of degradation reactions that most organic chemicals do; they are therefore considered persistent. The major fate mechanisms for metals are adsorption to the soil matrix and bioaccumulation.

The mobility of metals is influenced primarily by their physical and chemical properties, in combination with the physical and chemical characteristics of the soil matrix. Factors that help predict the mobility of inorganic species are the soil/pore-water pH (a measure of hydrogen-ion concentration used to express the acidity or alkalinity of a solution), soil/pore-water Eh (redox potential [referring to electron activity in soils], and cation-exchange capacity. pH and Eh allow us to understand the oxidation state of a metal in the environment. The oxidation state of a metal allows us to predict, to a certain extent, the mobility of the metal. The cation-exchange capacity (CEC) is one predictor of the tendency of metals to "bind" to the soil matrix thus limiting the potential for migration.

The mobility of metals generally increases with decreasing soil pH and cation-exchange capacity.

PAHs are fairly immobile chemicals in the environment. PAHs are large molecules with low solubilities, vapor pressures, and Henry's Law constants that have high partitioning coefficients. Both vapor pressure and water solubility are useful for determining volatilization rates from surface water bodies and groundwater. The measured ratio of these two parameters (the Henry's Law Constant) under equilibrium conditions is used to calculate the equilibrium chemical concentrations in the vapor (air) phase compared to the liquid (water) phase for the dilute solutions commonly encountered in environmental settings. In general, chemicals having a Henry's Law Constant less than 1×10^{-5} atm m^3/mole, such as PAHs, should volatilize very little and should be present only in minute amounts in the atmosphere or soil vapor. PAHs in soil are much more likely to bind to soil and be transported via mass-transport mechanisms than through dissolution. These compounds, when found in surface soil, generally do not migrate vertically to a great extent. Instead, they are more likely to adhere to soil particles and be removed from the site via surface water runoff and erosional processes, especially in the absence of pavement or if erosion controls are absent or not functioning properly. Naphthalene

is the only one of the PAH COPC considered volatile according to the USEPA RSL table (November 2011). Naphthalene is also the most soluble of the PAH COPC, and therefore is the most likely of the PAHs to be transported by groundwater.

PCBs are considered very persistent organic chemicals with a great affinity for particulates and organic matter (i.e., soil). However, PCBs may be mobilized via particulate transport due to erosion of contaminated surface soil. The primary PCB COPC in soil, Aroclor-1260, is not considered volatile according to the USEPA RSL table (November 2011) and thus is not considered volatile for purposes of calculating contaminant exposure and intake.

VOCs that may have been released/spilled onto surface soil would likely have volatilized over time. The lack of significant residual contamination in surface soils is evidence of this transport mechanism. VOCs not lost to the atmosphere may have migrated to subsurface strata and underlying groundwater via transport mechanisms. The VOCs, having low molecular weight with low adsorption potential, are considered very mobile in the environment. Trichloroethene is a primary VOC COPC, selected as a direct-contact COPC for groundwater and for migration to groundwater.

5.2.1.4 Potential Current and Future Receptors of Concern and Exposure Pathways

Current land use in the GSP area is commercial/industrial (MSA is an operating airport) and expected to remain so for the foreseeable future. The area surrounding MSA consists of suburban developments, industrial/commercial developments, and woodlands. The area surrounding GSP includes the MSA Main Terminal to the north, the runway to the east, Stansbury Creek to the west, and the Strawberry Point wooded area to the south. Groundwater is not currently used as a source of potable or industrial water at the site, and such use in the future is not anticipated. This HHRA considers receptor exposure under non-residential (e.g., industrial, recreational) land use scenarios. Although the site is unlikely to be used for residential purposes, residential land uses are also evaluated.

Current and/or potential/hypothetical future land uses suggest the following potential receptors could be exposed to impacted environmental media at GSP:

- *Construction workers*—Construction workers are plausible on-site adult receptors under current and future land uses. Construction workers could be exposed to chemicals in surface and subsurface soils (0–2 feet below grade and 2–15 feet below grade, respectively) through incidental ingestion and dermal contact, and through inhalation of airborne contaminants emanating from soil. Groundwater in the study area is within approximately 15 feet of the ground surface. Direct contact with the deeper (saturated-zone) soils is assumed limited and, thus, direct contact with soils deeper than approximately 15 feet below ground surface (bgs) will not be evaluated quantitatively. Such soils (i.e., the saturated-zone soils) will be evaluated qualitatively in the uncertainty analysis. Construction workers could also be exposed to chemicals in groundwater through incidental ingestion and dermal contact, and through inhalation of airborne contaminants emanating from groundwater.

- *Industrial workers*—Industrial workers are plausible on-site adult receptors under current and future land uses. These receptors could be directly exposed to chemicals in surface soils (0–2 feet below grade) through incidental ingestion, dermal contact, and inhalation of airborne particulates and vapors emitted from the soil. Industrial-worker exposure to subsurface soil (2–15 feet below grade) is unlikely. However, exposure to subsurface soil via incidental ingestion, dermal contact, and inhalation will be evaluated for this receptor to aid in risk management decisions because future construction could potentially bring subsurface soils to the surface. This receptor is expected to be exposed to soils equally as often (but less intensively) than would be the case for the construction worker.

  Industrial workers are not expected to be exposed to chemicals in groundwater because groundwater is not used as a source of either drinking water or process water, and because industrial workers are not expected to directly contact groundwater in their day-to-day work. If this receptor were to work in an on-site structure, they could be exposed to VOCs migrating from contaminated subsurface soils or groundwater into the indoor air of a building via vapor intrusion. However, industrial workers' exposure to chemicals through vapor intrusion would likely be less intensive than residential exposure to chemicals through vapor intrusion.

- *Child and adolescent trespassers/visitors*—Trespassers/visitors are plausible receptors under current and future land uses. A trespasser may be exposed to possibly contaminated surface soils through incidental ingestion, dermal contact, and inhalation of chemicals emitted from soil to the air. Trespasser exposure to subsurface soil is not likely unless future construction/excavation brings subsurface soil to the surface. To account for the possibility that subsurface soils could be disturbed through construction, trespassers were evaluated for exposure to subsurface soil (2–15 feet below grade), in addition to surface soil, to aid in risk management decisions. Direct contact with groundwater is unlikely for this receptor; thus, trespassers were not evaluated for groundwater exposure in this HHRA.

- *Child, adolescent, and adult recreational users*—Recreational users are plausible receptors under the future land use scenario. A recreational user may be exposed to possibly impacted surface soils (0–2 feet below grade) through incidental ingestion, dermal contact, and inhalation of chemicals emitted from soil to the air. To aid in future

risk management decisions, recreational users were evaluated for risks to subsurface soil (2–15 feet below grade) because future construction could redistribute subsurface soil to the surface. Recreational user direct contact with groundwater is unlikely, and therefore was not evaluated in this HHRA.

- *Future child, adolescent, and adult residents*—The hypothetical future residential scenario is typically evaluated in a risk assessment to facilitate risk management decisions. It is assumed that a hypothetical resident may be exposed to chemicals in surface soils (0–2 feet below grade) through ingestion, dermal contact, and inhalation of chemicals emitted from soil to air. To aid in risk management decisions, hypothetical residents will also be evaluated for risks posed by exposure to subsurface soil (2–15 feet below grade), since future construction could potentially redistribute subsurface soil to the surface. These hypothetical residents could also be exposed via inhalation to VOCs migrating (via vapor intrusion) from contaminated subsurface soils or groundwater into the indoor air of a home. Although unlikely, hypothetical residents were evaluated as though they will use site groundwater as their drinking-water source. For residents, potential exposures to chemicals in groundwater were evaluated for ingestion, dermal contact (during showering or bathing) and, for an adult resident only, exposure via inhalation of chemicals volatilized into the air during showering or bathing.

5.2.2 Central-Tendency Exposure versus Reasonable Maximum Exposure

Traditionally, exposures evaluated in an HHRA were based on the concept of a reasonable maximum exposure (RME), defined as "the maximum exposure that is reasonably expected to occur at a site" (USEPA, 1989). Subsequent risk assessment guidance (USEPA, 1992) stipulates the need to address an average case or central-tendency exposure (CTE). However, in this HHRA, only the RME scenario was evaluated because the RME scenario is designed to estimate the reasonable maximum exposure likely to occur, is more conservative than the CTE scenario, and is typically the basis of risk management decision-making.

5.2.3 Exposure-Point Concentrations

Exposure-point concentrations (EPC) calculated for COPC (both site-related and naturally occurring) are estimates of chemical concentrations in an EU; EPCs are used to estimate exposure intakes. An EU is the area over which receptor activity is expected. The following paragraphs discuss the EUs that will be evaluated in the HHRA, and the guidelines for calculating EPCs.

As described in Section 5.2.1, RECs #9 and #10 are adjacent to each other, but REC #11 is approximately 600 feet northwest of REC #10. Therefore, because REC #11 is geographically distinct from RECs #9 and #10, two EUs were evaluated: RECs #9 and #10 (evaluated as one

EU) and REC #11. Hypothetical future residential- and industrial-worker-exposures to contaminated soils were also evaluated on a location-by-location basis to determine if an EU has any significant contaminant "hot spots."

The additional evaluation for the industrial worker was conducted because the future land use of the study area will most likely be commercial/industrial. The additional evaluation for the hypothetical resident was conducted because this is the most sensitive and restrictive receptor (e.g., at some sites, exposure units as small as 0.25 acre have been selected for this receptor). The results of the location-by-location risk assessment are discussed in Section 5.4. The following guidelines were used to calculate EPCs for COPC concentrations in each EU:

- For soil data-sets containing at least 10 samples, the 95% upper confidence-limit (UCL) on the arithmetic mean, which is based on the distribution of the data set, was selected as the EPC unless the UCL value exceeded the maximum detected concentration. In that case, the maximum detected concentration was used as the EPC. The maximum concentration was also used as the EPC if an insufficient number of detections (i.e., less than three positive detections in a data set) to calculate a 95% UCL were available, in accordance with USEPA guidance (USEPA, 2010b). EPCs were calculated according to USEPA's *Calculating Upper Confidence-Limits for Exposure-Point Concentrations at Hazardous Waste Sites* (USEPA, 2002b) and using USEPA's *ProUCL* software (USEPA, 2010b).

- The maximum concentration of each groundwater COPC in each EU was used as the EPC for groundwater. This approach was used because fewer than 10 samples were available in each of the groundwater data sets. Fewer than 10 samples are included in each data set because, although two rounds of data were collected from the temporary monitoring wells, the maximum concentration for each chemical detected in the two rounds of sampling was used to represent the concentration for the associated well. This approach was taken so that the temporary wells were not over-represented in the groundwater data sets, as only one round of data exists for the permanent monitoring wells.

- The SQL was used as an input for non-detects in USEPA's *ProUCL* software to calculate the 95% UCL, in accordance with *ProUCL* guidance (USEPA, 2010b). Duplicates were averaged to calculate the EPC for COPC in environmental media in the study area.

- Naphthalene was selected as a global COPC for subsurface soil and groundwater in both the VOC and SVOC fractions. EPCs were calculated for naphthalene based on the results included in both fractions, and the greater EPC for naphthalene (in either the VOC or SVOC fraction) was then evaluated in the quantitative risk assessment for each EU. Uncertainty associated with this method is discussed in the uncertainty analysis.

- Section 5.1 notes that total chromium was selected as a COPC in surface soil, subsurface soil, and groundwater using hexavalent chromium screening criteria for COPC selection because no hexavalent chromium data were available for GSP. The *Remedial*

Investigation Report for Martin State Airport (Tetra Tech, 2010) evaluated the Dump Road Area and used available hexavalent chromium data to estimate the approximate percentage of hexavalent chromium in MSA soils. The results of that investigation show that approximately 1% of total chromium in MSA soils is in the hexavalent state. The remedial investigation conservatively assumed that 100% of the chromium detected in the Dump Road Area groundwater was in the hexavalent state (Tetra Tech, 2010). These Dump Road Area assumptions are also used in this GSP HHRA because no hexavalent chromium data are available for GSP, as follows: 1% of the total chromium EPC will be evaluated as hexavalent chromium for soil, and 100% of the total chromium EPC will be evaluated as hexavalent chromium for groundwater. Uncertainty associated with the assessment of chromium toxicity is discussed in Section 5.5.

Table 5-17 summarizes EPCs used in this HHRA. Tables 5-1 and 5-2 list the surface and subsurface soil samples, respectively, used to calculate EPCs in each EU. Table 5-4 lists the groundwater samples used to calculate EPCs for each EU. The *RAGS Part D* tables for the EPCs are in Appendix J.

5.2.4 Chemical Intake Estimation

This section presents methodologies and techniques for estimating exposure intakes. Intakes for the potential receptor groups identified were calculated using current MDE and USEPA risk assessment guidance and are in the risk assessment spreadsheets (see Appendix J). Exposure assumptions are in Table 5-18 and the *RAGS Part D* Table 4s.

Noncarcinogenic intakes are typically estimated using the concept of an average annual exposure. Carcinogenic intakes are calculated as an incremental lifetime-exposure, which assumes a life expectancy of 70 years. The exposure assumptions reflect current MDE guidance (State of Maryland, 2008). The primary guidance used to develop most of the exposure assumptions used to estimate chemical intakes are based on default assumptions described in the MDE guidance document (State of Maryland, 2008). Several USEPA guidance documents (e.g., USEPA, 1989, 1991, 1993a, 1997a, 2004a) were also consulted, as necessary. The following paragraphs discuss the non-default, receptor-specific exposure assumptions used in this risk assessment.

5.2.4.1 Incidental Ingestion of Soil

Direct physical contact with soil in the study area may result in incidental ingestion of chemicals. Daily chemical intakes, expressed in units of milligrams per kilogram per day (mg/kg/day), for the incidental ingestion of soil are estimated as follows (USEPA, 1989):

$$\text{Intake} = \frac{(C_s)(IR)(FI)(EF)(ED)(CF)}{(BW)(AT)}$$

where:

Intake	=	chemical intake from soil (mg/kg/day)
C_s	=	chemical concentration in soil (mg/kg)
IR	=	ingestion rate (mg/day)
FI	=	fraction ingested from contaminated source (dimensionless)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (year)
CF	=	conversion factor (1×10^{-6} kg/mg)
BW	=	body weight (kg)
AT	=	averaging time (days) for noncarcinogens, AT = ED×365 days/year for carcinogens, AT = 70 years×365 days/year

Most of the exposure assumptions used to estimate chemical intakes from incidental ingestion of soil are based on default assumptions described in MDE or USEPA guidance. They are summarized in Table 5-18. The following paragraph briefly discusses the receptor-specific exposure assumptions for incidental ingestion of soil used in the HHRA.

The exposure-frequency assumptions selected consider anticipated receptor activities at the study area. It was assumed that construction workers assigned to future excavation projects in the study area would be exposed to soil for 250 days per year (days/year) for one year. It was also assumed that the site recreational user would be exposed for 70 days per year and that child/adolescent trespassers would be exposed 52 days per year (i.e., an average of one day per week), based on professional judgment.

5.2.4.2 Dermal Contact with Soil

Direct physical contact with soil may result in dermal absorption of chemicals. Exposure associated with dermal contact with soil is estimated as follows (USEPA, 2004a):

$$\text{Intake} = \frac{(C_s)(SA)(AF)(ABS)(CF)(EV)(EF)(ED)}{(BW)(AT)}$$

where:

Intake = amount of chemical absorbed during contact with soil (mg/kg/day)

C_s = chemical concentration in soil (mg/kg)

SA = skin surface area available for contact (centimeters^2 [cm^2])

AF = skin adherence factor (mg/cm^2-event)

ABS = absorption factor (dimensionless)

CF = conversion factor (1×10^{-6} kg/mg)

EV = exposure event frequency (event/year)

EF = exposure frequency (days/year)

ED = exposure duration (year)

BW = body weight (kg)

AT = averaging time (days)
for noncarcinogens, AT = ED×365 days/year
for carcinogens, AT = 70 years×365 days/year

Most of the exposure assumptions used to estimate chemical intakes from dermal contact with soil are based on the default assumptions described in the standard MDE or USEPA guidance. They are summarized in Table 5-18. The following paragraph briefly discusses the receptor-specific exposure assumptions for dermal contact with soil used in the HHRA. The same exposure frequencies and durations recommended for evaluating incidental ingestion of soil are used to estimate chemical intakes for dermal contact with soil.

The exposed skin surfaces of the body available for dermal contact with soils are determined on a receptor-specific basis, since they correspond with assumed human activities and clothing worn

during exposure events. All of the skin surface areas presented in Table 5-18 are based on MDE or USEPA default values. For adolescent receptors, the skin surface area available for soil contact is set at 4,320 square centimeters (cm^2) (based on Maryland guidance; see State of Maryland, 2008). The skin surface area available for soil contact for construction workers is assumed to be 3,280 cm^2, based on Maryland guidance (State of Maryland, 2008).

For chemicals identified as COPC in soil, the chemical-specific dermal absorption factors in *RAGS Part E* (USEPA, 2004a) were used to evaluate the COPC for soil. USEPA Region 3 dermal guidance (USEPA, 2003a) was consulted if chemical-specific absorption factors are not available in *RAGS Part* E. Dermal-absorption factors used in this risk assessment are in Table 5-21.

5.2.4.3 Inhalation of Air Containing Fugitive Dust/Volatiles Emitted from Soil

Intakes of both particulates and vapors/gases are calculated using the same equation, as follows (USEPA, 2009):

$$EC = \frac{(C_{air})(ET)(EF)(ED)}{AT \times 24\ hrs/day}$$

where:

EC = exposure concentration (mg/m^3)

C_{air} = concentration of chemical in air (mg/m^3)

ET = exposure time (hours/day)

EF = exposure frequency (days/year)

ED = exposure duration (year)

AT = averaging time (days)
for noncarcinogens, AT = ED×365 days/year
for carcinogens, AT = 70 years×365 days/year

Most of the exposure assumptions used to estimate chemical intakes from inhalation of fugitive dusts/volatile emissions from surface and subsurface soils are based on default assumptions described in the Maryland guidance or the standard USEPA guidance. They are summarized in Table 5-18. The same exposure frequencies and durations used to estimate incidental ingestion of

soil intakes are used to estimate exposure via inhalation of fugitive dust/volatile emissions for surface and subsurface soils.

The concentrations of chemicals in air resulting from emissions from soil are developed following procedures presented in USEPA *Soil Screening Guidance* (USEPA, 2002a). The chemical concentration in air is calculated from:

$$C_{air} = C_{soil} \times \left[\frac{1}{PEF} + \frac{1}{VF} \right]$$

where:

C_{air} = chemical concentration in air, mg/m^3

C_s = chemical concentration in soil, mg/kg

PEF = particulate-emission factor, m^3/kg

VF = volatilization factor, m^3/kg

The particulate-emissions factor (PEF) relates the concentration of the chemical in soil to the concentration of dust particles in air. A PEF value of $3.23 \times 10^{+9}$ cubic meters per kilogram (m^3/kg) was obtained from USEPA's soil-screening Web site (http://rais.ornl.gov/epa/ssl1.shtml). This is the default value for Philadelphia, Pennsylvania, which is the closest city to the MSA listed on the Web site. A separate PEF is used for the construction scenario because air emissions from fugitive dust emissions at non-construction settings differ from dust emissions generated by construction. The PEF for construction workers ($1.43 \times 10^{+6}$ m^3/kg) was calculated using the equations presented in the supplemental SSL guidance document (USEPA, 2002a). A sample calculation showing how the PEF was calculated is in Appendix J.

Ambient air concentrations resulting from the volatilization of COPC from soil are chemical dependent and calculated using the following equation from USEPA's soil-screening guidance:

$$VF = \frac{Q/C \times (3.14 \times D_a \times T)^{0.5} \times 10^{-4} \ (m^2/cm^2)}{(2 \times \rho_b \times D_a)}$$

and

$$D_a = \frac{[(\theta_a^{10/3} \times D_i \times H' + \theta_w^{10/3} \times D_w)/n^2]}{\rho_b \times K_d + \theta_w + \theta_a \times H'}$$

where:

VF = volatilization factor (m^3-air/kg-soil)

Q/C = inverse of the mean concentration at the center of source (grams [g]/m^2-sec per kg/m^3)

D_a = apparent diffusivity, chemical specific, (cm^2/sec)

T = exposure interval, exposure-specific, (seconds [sec])

ρ_b = dry bulk-soil-particle density (g/cm^3)

θ_a = air-filled-soil porosity (L_{air}/L_{soil})

D_i = diffusivity in air, chemical specific, (cm^2/sec)

n = total soil porosity (L_{pore}/L_{soil})

θ_w = water-filled-soil porosity (L_{air}/L_{soil})

D_w = diffusivity in water, chemical specific, (cm^2/sec)

K_d = soil-water-partition coefficient, chemical specific

H' = dimensionless Henry's Law constant, chemical specific

Chemical properties were obtained from the current USEPA RSL table and are presented in Table 5-19. Input assumptions for calculating the volatilization factor (VF) are in Table 5-20.

5.2.4.4 Direct/Incidental Ingestion of Groundwater

Direct ingestion of groundwater at GSP is likely limited to exposure that would occur under a future residential scenario. Incidental ingestion of groundwater by construction workers may occur during construction or excavating. Intakes associated with groundwater ingestion will be evaluated using the following equation (USEPA, 1989):

$$\text{Intake} = \frac{(C_w)(IR_w)(EF)(ED)}{(BW)(AT)}$$

where:

Intake	=	chemical intake from groundwater (mg/kg/day)
C_w	=	chemical concentration in groundwater (mg/L)
IR_w	=	groundwater-ingestion rate (L/day)
ET	=	exposure time (hrs/day)
EF	=	exposure frequency (days/yr)
ED	=	exposure duration (yr)
BW	=	body weight (kg)
AT	=	averaging time (days) for noncarcinogens, AT = ED×365 days/year for carcinogens, AT = 70 years×365 days/year

MDE or USEPA standard default exposure-assumptions were used to evaluate residential exposures to groundwater. For construction workers, an ingestion rate of 0.2 liters per day (L/day) (or 50 milliliters per hour [mL/hr] for four hours) was assumed for 90 days per year, for an exposure duration of one year. An exposure frequency of 90 days per year assumes that construction workers contact groundwater approximately three months per year. A summary of the receptor-specific input values used to estimate chemical intakes from direct and incidental ingestion of groundwater is in Table 5-18.

5.2.4.5 Dermal Contact with Groundwater

Dermal contact with groundwater at the GSP is limited to exposure that would occur under residential and construction scenarios. Hypothetical future site residential receptors are assumed to use groundwater for domestic purposes (i.e., bathing, showering, and dish washing) that could result in dermal exposure. Short-term dermal exposure is assumed to occur for the construction worker during excavating.

The following equation is used to assess exposures from dermal contact with groundwater (USEPA, 2004a):

$$DAD = \frac{(DA_{event})(EV)(ED)(EF)(SA)}{(BW)(AT)}$$

where:

DAD = dermally absorbed chemical-dose from water (mg/kg/day)

DA_{event} = dermally absorbed dose per event (mg/cm^2-event)

EV = event frequency (events/day)

ED = exposure duration (year)

EF = exposure frequency (days/year)

SA = skin-surface area available for contact (cm^2)

BW = body weight (kg)

AT = averaging time (days)
for noncarcinogens, AT = ED×365 days/year
for carcinogens, AT = 70 years×365 days/year

Most of the exposure assumptions used to estimate chemical intakes from dermal contact with groundwater are based on default assumptions described in the standard MDE or USEPA guidance, and summarized in Table 5-18.

Dermal intakes for residents assume daily total-body exposure. Child and adult surface area values are based on USEPA guidance. For adolescents, a total body-surface area of 13,100 cm^2 was used; this value is based on Maryland guidance (State of Maryland, 2008). For construction workers, the exposed surface area of the body available for contact is based on assumed activities, and is similar to the assumptions outlined for dermal contact with soil.

USEPA has not established default exposure-frequency assumptions for a construction worker exposed to groundwater. Consequently, we assume that the construction worker would be exposed to groundwater for four hours per day for 90 days per year. A shorter exposure frequency is recommended for a construction worker exposed to groundwater than that recommended for exposure to soil, because a construction worker would be unlikely to have direct daily contact with groundwater during a construction project.

The absorbed dose per event (DA_{event}) was estimated using a non-steady-state approach for organic compounds and a traditional steady-state approach for inorganics. For organics, the following equations apply:

$$\text{If } t_{event} < t^*, \text{ then: } DA_{event} = (2)(K_p)(FA)(C_w)(CF)\left(\sqrt{\frac{6\,\tau\,t_{event}}{\pi}}\right)$$

$$\text{If } t_{event} > t^*, \text{ then: } DA_{event} = (K_p)(FA)(C_w)(CF)\left(\frac{t_{event}}{1+B} + 2\,\tau\left(\frac{1+3B+3B^2}{(1+B)^2}\right)\right)$$

where:

t_{event}	=	event duration (hour/event)
t*	=	time to reach steady-state conditions (hour)
K_p	=	permeability coefficient of water through skin (cm/hour)
FA	=	chemical-specific fraction absorbed (dimensionless)
C_w	=	chemical concentration in water (mg/L)
τ	=	lag time (hour)
π	=	Pi (dimensionless; equal to 3.1416)
CF	=	conversion factor (0.001 L/cm^3)
B	=	dimensionless ratio of the permeability of the *stratum corneum* relative to permeability across the viable epidermis

Values for the chemical-specific parameters (t*, K_p, FA, τ, and B) were obtained from the current dermal guidance (USEPA, 2004a, Exhibit B-3) and are presented in Table 5-21. If published values are not available for a particular compound, they were calculated using equations provided in the USEPA dermal guidance.

The following steady-state equation was used to estimate DA_{event} for inorganics:

$$DA_{event} = (K_p)(C_{wi})(t_{event})$$

The dermal permeability (K_p) values recommended in the USEPA dermal guidance (USEPA, 2004a) were used to calculate DA_{event} for inorganic COPC.

5.2.4.6 Inhalation of Volatiles in Groundwater

If VOCs are present, groundwater exposure may also result in chemical intake through inhalation if the water resource is used as a domestic water supply or is exposed during construction

activities. This exposure route is plausible for residential receptors that may be exposed while showering, bathing, washing dishes, etc., or for construction workers contacting shallow groundwater during excavation activities. For residential receptors, chemical intakes from inhalation exposure while showering (due to volatilization of COPC in groundwater) were estimated using a mass-transfer model, developed specifically for this exposure route, in combination with an air-intake-estimation model. The mass-transfer model accounts for inhalation during and after a shower while the receptor remains in a closed bathroom. The method used is as follows (USEPA, 1989, and Foster and Chrostowski, 1987, USEPA, 2009):

$$EC = (S)(ET)(K)(EF)(ED) /(AT)(R_a)(CFs)$$

$$K = D_S + \frac{\exp(-R_a \times D_t)}{R_a} - \frac{\exp\left[R_a \times (D_S - D_t)\right]}{R_a}$$

where:

EC = exposure concentration (mg/m^3)

S = volatile-chemical generation rate ($\mu g/m^3$-min—shower)

ET = exposure time (hours/day)

EF = exposure frequency (showers/year)

ED = exposure duration (year)

AT = averaging time or period of exposure (hours)
for noncarcinogens, AT = ED×365 days/year×24 hours/day;
for carcinogens, AT = 70 yr×365 days/year x24 hours/day

R_a = air-exchange rate (min^{-1})

K = mass-transfer coefficient (min)

D_s = shower duration (min)

D_t = total time in bathroom (min)

CFs = conversion factors ($1\times10^{+3}$ µg/mg and 1,440 min/day)

The estimated volatile-chemical-generation rate is based on two-phase-film theory. The model uses contaminant-specific mass-transfer coefficients, Henry's Law constants, droplet diameter,

drop time, viscosity, temperature, etc. A sample calculation is in Appendix J. The same exposure frequencies and durations used to estimate intake for dermal contact with groundwater are used to evaluate chemical intakes for inhalation of VOCs from domestic groundwater use.

Inhalation exposures for the construction worker were estimated using an air-intake estimation model, as follows (USEPA, 2009):

$$EC = \frac{(C_{air})(ET)(EF)(ED)}{(AT)(24\ hrs/day)}$$

where:

EC	=	exposure concentration (mg/m^3)
C_{air}	=	chemical concentration in air (mg/m^3)
ET	=	exposure time (hours/day)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (year)
AT	=	averaging time (days) for noncarcinogens, AT = ED×365 days/year for carcinogens, AT = 70 year×365 days/year

Construction workers may be exposed to COPC that have volatilized from groundwater when an excavation exposes the shallow water table. The same exposure frequencies and times used to estimate intake from dermal contact with groundwater are used to evaluate intake from inhalation of VOCs from groundwater during construction.

No well-established models are available for estimating migration of volatiles from groundwater into a construction or utility trench. To estimate the EPC for air in a construction trench, the HHRA used an approach suggested by the Virginia Department of Environmental Quality (VDEQ) (2004), which is based on a combination of a vadose-zone model (to estimate volatilization of gases from contaminated groundwater into a trench) and a box model (to estimate contaminant dispersion from the air inside the trench to the above-ground atmosphere). The VDEQ methodology is described in the following paragraphs. The airborne concentration of a contaminant in a trench can be estimated using the following equation:

$$C_{air} = C_{gw} \times VF$$

where:

C_{air} = contaminant concentration in trench air µg/m^3

C_{gw} = concentration of contaminant in groundwater µg/L

VF = volatilization factor L/m^3

We assumed that a construction project at the site could excavate 15 feet below grade or less. If the depth to groundwater at a site is less than 15 feet, the VDEQ model assumes that a worker would encounter groundwater when digging an excavation or trench and thus be directly exposed to the groundwater. The worker would also be exposed to airborne contaminants inside the trench due to volatilization from groundwater pooling in the trench bottom. The following equation is used to calculate the VF for a trench less than 15 feet deep:

$$VF = (Ki \times A \times F \times 10^{-3} \times 10^{4} \times 3{,}600)/(ACH \times V)$$

where:

VF = volatilization factor (L/m^3)

K_i = contaminant's overall mass-transfer coefficient (cm/s)

i = contaminant of interest

A = trench area (m^2)

F = fraction of floor through which contaminant can enter (unitless)

ACH = air changes per hour (h^{-1}) = 360 h^{-1}

V = trench volume (m^3)

10^{-3} = conversion factor (L/cm^3)

10^4 = conversion factor (cm^2/m^2)

3,600 = conversion factor (seconds/hour)

Studies of urban canyons suggest that if the ratio of trench width, relative to wind direction and trench depth, is less than or equal to 1, a circulation cell(s) will be created in the trench, limiting the degree of gas exchanged with the atmosphere. Thus, measured building-ventilation rates lead

to an assumption of two air changes per hour (ACH). If the width to depth ratio of the trench is greater than 1, the air exchange between the trench and above-ground atmosphere is unrestricted, based on the ratio of trench depth to average wind speed, so the ACH is assumed to be 360. The exposure assessment in this HHRA assumes that the width-to-trench depth ratio is greater than 1; thus, the ACH is set at 360.

K_i is calculated using the following equation:

$$K_i = 1/\{(1/k_iL) + [(RT)/(H_i\ k_iG)]\}$$

where:

K_i	=	contaminant's overall mass-transfer coefficient (cm/s)
i	=	contaminant of interest
k_iL	=	liquid-phase mass-transfer coefficient of i (cm/s)
R	=	ideal gas-constant (atm-m^3/mole-°K) = 8.2×10^{-5}
T	=	average system absolute-temperature (°K) (Default = 298°K)
H_i	=	Henry's Law constant of i (atm-m^3/mole)
k_iG	=	gas-phase mass-transfer coefficient of i (cm/s)

Formulae for calculating k_iL and k_iG are as follows:

$$k_iL = (MWO_2/MW_i)^{0.5}\times(T/298)\times kL,O_2$$

where:

k_iL	=	liquid-phase mass-transfer coefficient of component i (cm/s)
MWO_2	=	molecular weight of oxygen (g/mole)
MW_i	=	molecular weight of component i (g/mole)
kL,O_2	=	liquid-phase mass-transfer coefficient of oxygen at 25°C (cm/s) = 0.002 cm/s

$$k_iG = (MWH_2O/MW_i)^{0.335} \times (T/298)^{1.005 \times} kG,H_2O$$

where:

k_iG	=	gas-phase mass-transfer coefficient of component i (cm/s)
MWH_2O	=	molecular weight of water (g/mole)
kG,H_2O	=	gas-phase mass-transfer coefficient of water vapor at 25°C (cm/s)
	=	0.833 cm/s (*Superfund Exposure Assessment Manual*, USEPA, 1988)

Chemical properties were obtained from the *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA, 2002a) and are presented in Table 5-19.

5.2.4.7 Assessing Cancer Risks from Early-Life Exposures

USEPA's *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (USEPA, 2005b) recommends adjusting the toxicity of carcinogenic chemicals that act mutagenically (i.e., produce genetic changes) when evaluating early-life exposures to such contaminants. The guidance recommends using age-dependent adjustment factors (ADAFs) in concert with age-specific exposure estimates when assessing cancer risks. If chemical-specific data are absent, the supplemental guidance recommends the following default adjustments, which reflect that cancer risks are generally higher from early-life exposures than from similar exposures later in life:

- for exposures before two years of age (i.e., spanning a two-year interval from the first day of birth until a child's second birthday), a 10-fold adjustment
- for exposures between age two and less than 16 years of age (i.e., spanning a 14-year interval from a child's second birthday until their sixteenth birthday), a three-fold adjustment
- for exposures after reaching 16 years of age, no adjustment

These adjustments were applied using the same method as that used by USEPA to develop the RSLs. Children were evaluated in two age groups: ages 0–2 and 2–6 years old. Adolescents will be evaluated as two age groups: 6–16 and 16–18 years old. Adults (except for the adult commercial/industrial worker and construction worker) were evaluated as one age group (18–30 years old). (For the adult commercial/industrial workers, the MDE default exposure-duration of

25 years was used. A one-year exposure duration was used for the construction worker. No ADAFs are applied to these receptors.)

Using this approach, the intakes for child and adolescent trespassers; child, adolescent, and adult recreational users; and hypothetical child, adolescent, and adult residents are calculated as follows:

$$Intake_{Child} = Intake_{(ages\ 0—2\ years)} \times 10 + Intake_{(ages\ 2—6\ years)} \times 3$$

$$Intake_{Adolescent} = Intake_{(age\ 6—16\ years)} \times 3 + Intake_{(age\ 16—18\ years)} \times 1$$

$$Intake_{Adult} = Intake_{(ages\ 18—30\ years)} \times 1$$

This approach is used only for chemicals identified as mutagenic in the USEPA RSL screening table (e.g., BaPEq constituents, hexavalent chromium). Risks to receptors involving different age groups are sums of the cancer risks calculated for individual children, adolescents, and adult receptors. Therefore, lifelong cancer-risks from chemicals that act via the mutagenic pathway are assessed through the lifelong-recreational-user and lifelong-resident receptor scenarios.

5.2.4.8 Vapor Intrusion into Buildings

Current/future industrial workers and hypothetical residents could be exposed to COPC that have volatilized from groundwater and migrated into indoor air through future building foundations. Indoor air concentrations resulting from vapor intrusion from groundwater were not estimated using the Johnson and Ettinger volatilization model (USEPA, 2004b) due to the uncertainty associated with that model. Instead, vapor intrusion COPC are qualitatively evaluated in Section 5.4.

5.2.4.9 Exposure to Lead

The equations and methodology presented in the previous section cannot be used to evaluate exposure to lead because of the absence of published dose-response parameters. However, lead was not selected as a direct-contact COPC for any medium in this HHRA. Thus, quantitative methods for evaluating lead are not discussed in this HHRA.

5.2.4.10 Summary of Exposure Parameters

Table 5-18 summarizes exposure input-parameters for all exposure pathways for identified potential receptor groups in the study area. In general, standard default-parameters from MDE guidance (State of Maryland, 2008) or USEPA guidance (e.g., USEPA, 1989, 1991, 1997a, 2004a), which combine mid-range and upper-end exposure factors, were used to assess RME conditions. CTE is not assessed in this HHRA.

5.3 TOXICITY ASSESSMENT

The toxicity assessment seeks to identify potential adverse health effects in exposed populations. Quantitative estimates of the relationship between the magnitude and type of exposures, and the severity or probability of human health effects, are defined for the identified constituents of concern (see Tables 5-22 through 5-25). Quantitative toxicity-values determined during this component of the risk assessment are integrated with exposure-assessment outputs to characterize the potential occurrence of adverse health effects for each receptor group.

The reference dose (RfD) is the toxicity value used to evaluate noncarcinogenic health effects for ingestion and dermal exposures. The reference concentration (RfC) is used to evaluate noncarcinogenic health effects for inhalation exposures. The RfD and RfC estimate a daily exposure level for a human population that is unlikely to pose an appreciable risk during a portion or for all of a human lifetime. They are based on a review of animal and/or human toxicity data with adjustments for various data uncertainties. Carcinogenic effects are quantified using the cancer slope-factor (CSF) for ingestion and dermal exposures, and using inhalation-unit risks (IURs) for inhalation exposure that are plausible upper-bound estimates of the probability of developing cancer per unit-intake of the chemical over a lifetime. These are typically based on dose-response data from human and/or animal studies.

5.3.1 Toxicity Criteria for Oral and Inhalation Exposures

Oral RfDs and CSFs and inhalation RfCs and IURs used in the risk assessment of the study area were obtained from the following primary USEPA sources (USEPA, 2003b):

- ***IRIS***—USEPA's Integrated Risk Information System online database

- ***USEPA's Provisional Peer Reviewed Toxicity Values (PPRTVs)—***USEPA's Office of Research and Development/National Center for Environmental Assessment (NCEA) Superfund Health Risk Technical Support Center develops chemical specific PPRTVs when requested by USEPA's Superfund program

- ***Other toxicity values—***These sources include, but are not limited to, California Environmental Protection Agency (Cal/EPA) toxicity values, federal Agency for Toxic Substances and Disease Registry (ATSDR) values, and USEPA's *Health Effects Assessment Summary Tables* (HEAST) (USEPA, 1997b)

Although toxicity criteria can be found in several toxicological sources, USEPA's *IRIS* online database is the preferred source of toxicity values. This database is continuously updated and its values are verified by USEPA.

5.3.2 Toxicity Criteria for Dermal Exposure

RfDs and CSFs in the scientific literature are typically expressed as "administered" (i.e., not absorbed) doses. Therefore, these values are considered inappropriate for estimating risks associated with dermal exposures without adjustment to account for incomplete absorption. Oral dose-response parameters based on administered doses must be adjusted to absorbed doses before they can be compared to estimated dermal-exposure intakes.

When oral absorption is essentially complete (i.e., 100%), an absorbed dose is equivalent to the administered dose, so no toxicity adjustment is necessary. Conversely, when the gastrointestinal absorption of a chemical is poor (e.g., 1%), the absorbed dose is smaller than the administered dose; thus, toxicity factors based on absorbed dose should be adjusted to account for the difference in the absorbed dose relative to the administered dose. USEPA (2004a) recommends a 50% absorption cut-off to reflect the intrinsic variability in analyzing absorption studies. Therefore, the adjustment from administered to absorbed dose was only performed when the chemical-specific gastrointestinal-absorption efficiency was less than 50%. The adjustment from administered to absorbed dose was made using chemical-specific gastrointestinal-absorption efficiencies published in numerous sources of guidance (e.g., USEPA 2004a [the primary reference], *IRIS*, and Agency for Toxic Substances and Disease Registry (ATSDR) toxicological profiles, etc.), using the following equations:

$$RfD_{dermal} = (RfD_{oral})(ABS_{GI})$$

$$CSF_{dermal} = (CSF_{oral}) \; / \; (ABS_{GI})$$

where:

ABS_{GI} = absorption efficiency in the gastrointestinal tract

RfD_{dermal} = reference dose for dermal exposures

RfD_{oral} = reference dose for oral exposures

CSF_{dermal} = cancer slope-factor for dermal exposures

CSF_{oral} = cancer slope-factor of oral exposures

As noted, the preceding adjustment of the oral-toxicity criteria (i.e., RfDs, CSFs) is necessary so that the dermal route of exposure may be quantitatively evaluated in the baseline risk assessment. Further explanation of this procedure and its necessity are presented in Appendix A of USEPA *RAGS Part A*.

5.3.3 Inhalation Toxicity-Values for Construction Workers

Under Superfund guidelines, exposures to construction workers of one year or less are classified as subchronic exposures. Risks for noncarcinogenic effects associated with subchronic exposures should incorporate toxicity values for subchronic and not chronic effects. Tables 5-22 and 5-23 display the available subchronic RfDs and RfCs, respectively, that were used for the construction worker. Uncertainty associated with the lack of subchronic RfDs and RfCs for many chemicals is discussed in Section 5.5.3.

5.3.4 Chromium Toxicity

Toxicity criteria are available for different forms of chromium, which is considered more toxic in the hexavalent state. In the USEPA's most recent RSL table, hexavalent chromium is listed as a carcinogen that has been determined to act "mutagenically;" the corresponding RSL for residential soil is less than 1 mg/kg. USEPA's *Guidelines for Carcinogen Risk Assessment* (USEPA, 2005a) and *Supplemental Guidance on Assessing Susceptibility from Early-Life Exposure to Carcinogens* (USEPA, 2005b) specify the use of ADAFs for carcinogens, such as chromium, that act mutagenically. In contrast, the RSL for residential soil for trivalent chromium (not listed as a carcinogen/mutagen) is 120,000 mg/kg.

No hexavalent chromium data were available for GSP. As discussed in Section 5.1, hexavalent chromium criteria were used conservatively to evaluate total chromium in COPC selection, and

chromium was selected as a COPC for surface soil, subsurface soil, and groundwater on this basis. The *Remedial Investigation for Martin State Airport* (Tetra Tech, 2010), which evaluated the Dump Road Area, assumed that 1% of the reported total-chromium result in soil was attributed to hexavalent chromium; this percentage was based on comparing the analytical results of total and hexavalent concentrations in soil. Therefore, the same assumption was used in this HHRA for GSP.

The use of 1% of the total chromium concentration as the hexavalent chromium concentration is conservative, as available hexavalent chromium results indicate that hexavalent chromium, when detected, was most often much less than 1% of the total chromium result in soil. As discussed in the uncertainty section, this overestimates the risks of exposure to chromium, but does not affect overall HHRA conclusions. For groundwater, total-chromium data were conservatively evaluated using hexavalent-chromium toxicity criteria. Uncertainty associated with chromium data in groundwater is discussed in the uncertainty section.

As discussed in the uncertainty section, assuming 1% of total chromium as hexavalent chromium in soil, and using hexavalent-chromium toxicity criteria for groundwater, overestimates the risks of exposure to chromium but does not affect overall HHRA conclusions. No chemical-specific ADAFs have been derived for hexavalent chromium; therefore, the following default ADAFs were used: 10 for ages 0–2, 3 for ages 2–16, and 1 (no adjustment) for ages 16–70. These ADAFs were used to evaluate exposures to hexavalent chromium for trespassers, recreational users, and hypothetical residents using the approach presented in Section 5.2.4.7.

5.3.5 Toxicity of PCBs

The HHRA for PCBs was conducted per the guidance in USEPA's *PCBs: Cancer Dose-Response Assessment and Application to Environmental Mixtures* (USEPA, 1996b). This guidance presents a tiered approach to assessing the risks of PCBs. A range of CSFs for PCBs is presented for use in HHRA according to criteria that consider the environmental media under investigation, the type of exposure, and the anticipated persistence, bioaccumulation potential, and toxicity of PCB homologues/congeners detected in the samples.

5.3.6 Toxicity Criteria for the Carcinogenic Effects of PAHs

Limited toxicity values are available to evaluate the potential carcinogenic effects from exposure to PAHs. Benzo(a)pyrene is the most extensively studied PAH and the USEPA has published a cancer slope-factor for this PAH in *IRIS* (USEPA, 1993b). However, CSFs have not been published in *IRIS* for other PAH compounds. Alternatively, for a sub-set of related PAH chemicals (benzo[a]anthracene, benzo[b]fluoranthene, benzo[k]fluoranthene, chrysene, dibenzo[a]anthracene, indeno[1,2,3-cd]pyrene), USEPA recommends that risk evaluations be conducted using the TEFs developed for and used by the agency to relate the potency of each of these PAHs to that of benzo(a)pyrene (USEPA, 1993b).

Specifically, TEFs are used to convert the individual PAH concentrations into an equivalent concentration of benzo(a)pyrene, referred to as the BaPEq. For example, the TEF currently used by USEPA to develop the screening levels for chrysene presented in the USEPA RSL table is 0.001 (USEPA, 2011b, USEPA, 1993b). Consequently, if the detected chrysene concentration in a soil sample is 10,000 µg/kg, the benzo(a)pyrene equivalent concentration is 10 µg/kg. If benzo(a)pyrene and chrysene are the only PAHs detected in a sample and each was detected at 10,000 micrograms per kilogram (µg/kg), the associated benzo(a)pyrene equivalent concentration (based on positive detections only) would be 10,010 µg/kg (10,000 µg/kg for benzo[a]pyrene and 10 µg/kg for chrysene). This equivalent concentration, calculated for each sample, is then further evaluated in the risk assessment.

As discussed above, USEPA's *Guidelines for Carcinogen Risk Assessment* (USEPA, 2005a) and *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (USEPA, 2005b) specify the use of ADAFs for carcinogens that act mutagenically. BaPEq constituents are included in the group of chemicals determined to act mutagenically. No chemical specific ADAFs have been derived for BaPEq; therefore, the following default ADAFs were used: 10 for ages 0–2, 3 for ages 2–16, and 1 (no adjustment) for ages 16–70. These ADAFs are used to evaluate exposures to BaPEq for trespassers, recreational users, and hypothetical residents using the approach presented in Section 5.2.4.7.

5.3.7 Carcinogenic Toxicity Criteria for Trichloroethene

Toxicity factors for trichloroethene (TCE) were finalized by USEPA in September 2011. Toxicity factors for TCE address both carcinogenic and noncarcinogenic effects. Toxicological studies indicate that exposure to TCE increases the risk of kidney and liver cancer and non-Hodgkin's lymphoma. A sufficient weight of evidence suggests that TCE-induced kidney tumors are a result of a mutagenic mode of action. USEPA *Guidelines for Carcinogen Risk Assessment* (USEPA, 2005a) and *Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens* (USEPA, 2005b) specify the use of ADAFs for carcinogens that act via a mutagenic mode of action. However, these ADAFs will only be applied to a portion of the CSF and IUR that is attributable to kidney-induced tumors.

The oral CSF for TCE is 4.6×10^{-2} $(mg/kg\text{-}day)^{-1}$ and the IUR is 4.1×10^{-6} $(\mu g/m^3)^{-1}$. For the kidney mutagenic endpoint, the oral CSF is 9.3×10^{-3} $(mg/kg\text{-}day)^{-1}$ and the IUR is 1×10^{-6} $(\mu g/m^3)^{-1}$. No chemical-specific ADAFs are available for the kidney mutagenic endpoint; therefore, USEPA's default ADAFs are applied to the carcinogenic toxicity-factors for the kidney-related component of TCE's carcinogenic toxicity-factors. The following default ADAFs should be applied: 10 for ages 0–2, 3 for ages 2–16, and 1 (no adjustment) for ages 16–70. For the liver cancer and non-Hodgkin's lymphoma endpoints, the oral CSF is 3.7×10^{-2} $(mg/kg\text{-}day)^{-1}$ and the IUR is 3×10^{-6} $(\mu g/m^3)^{-1}$. No ADAFs are applied to these values. Noncarcinogenic effects are evaluated (like all noncarcinogens) in accordance with USEPA's risk assessment guidance (USEPA, 1989).

5.3.8 Carcinogenic Toxicity Criteria for Vinyl Chloride

Toxicity factors for vinyl chloride address both carcinogenic and noncarcinogenic effects. Vinyl chloride-induced carcinogenesis is a result of a mutagenic mode of action, and this is addressed in a chemical-specific manner in the risk assessment. Toxicological studies in animals have shown an increased sensitivity to vinyl chloride-induced carcinogenesis in early life and from prenatal exposure. Early-life data on humans is lacking because most exposures have been limited to occupational groups. However, many of the factors likely responsible for early-life sensitivity in animals are present in humans (USEPA, 2000).

The effects of early-life exposure are qualitatively and quantitatively different from those of later exposures. Therefore, prorating early-life exposures as if they had been received at a proportionately lesser rate over a full lifetime would not be appropriate. Estimating risks from birth (e.g., child from ages 0–6) thus requires summing a non-prorated "early-life risk" and a prorated "later-life risk" over a life span of 70 years. No early-life component exists in cases where the receptor is not being exposed from birth. The later-life component is pro-rated as the defined exposure-duration over an assumed life span of 70 years. Noncarcinogenic effects are evaluated like all noncarcinogens, in accordance with USEPA's risk assessment guidance (USEPA, 1989).

5.4 RISK CHARACTERIZATION

This section characterizes the potential human health risks associated with exposures to COPC at GSP. Potential risks (noncarcinogenic and carcinogenic) for human receptors from exposures, as outlined in the exposure assessment, were quantitatively determined during the risk characterization component of this HHRA. Sections 5.4.1 and 5.4.2 outline the methods used to quantitatively estimate the type and magnitude of potential risks to human receptors. Summaries of the risk characterization for GSP are provided in Section 5.4.3.

5.4.1 Quantitative Analysis of Constituents Other Than Lead

Quantitative estimates of risk for chemicals other than lead are calculated according to risk assessment methods outlined in USEPA guidance (USEPA, 1989). Lifetime cancer-risks are expressed in the form of dimensionless probabilities referred to as ILCRs, based on CSFs and IURs. Noncarcinogenic-risk estimates are presented in the form of HQs, which are determined by comparing intakes against published RfDs and RfCs. ILCR estimates for ingestion and dermal exposures were generated for each COPC using estimated exposure-intakes and published CSFs, as follows:

$$ILCR = (\text{Estimated Exposure Intake})(CSF)$$

If the equation above produces an ILCR greater than 0.01, the following equation was used:

$$ILCR = 1-[\exp(-\text{Estimated Exposure Intake})(CSF)]$$

ILCR estimates of inhalation exposures are generated for each COPC using estimated exposure concentrations and published IURs, as follows:

$$ILCR = (IUR)(ExposureConcentraton)(1000\,\mu g/mg)$$

An ILCR of 1×10^{-6} indicates that the exposed receptor has a one in a million chance of developing cancer under the defined exposure scenario. Alternatively, such a risk may be interpreted as representing one additional case of cancer in an exposed population of one million persons.

Noncarcinogenic risks will be assessed using the concept of HQs and hazard indices (HIs). The HQ for a COPC is the ratio of the estimated intake to the RfD, and is calculated for ingestion and dermal exposures as follows:

$$HQ = (\text{Estimated Exposure Intake}) \,/\, (RfD)$$

For inhalation exposures, the HQ is calculated as follows:

$$HQ = (ExposureConcentraton)/(RfC)$$

An HI was generated by summing the individual HQs for all COPC. The HI is not a mathematical prediction of the severity of toxic effects and therefore is not a true probabilistic "risk;" it is simply a numerical indicator of the possibility of the occurrence of noncarcinogenic (threshold) effects.

5.4.2 Interpretation of Risk Assessment Results

To interpret the quantitative risk estimates and aid risk managers in determining the need for remediation, quantitative risk estimates are compared to typical MDE and USEPA risk benchmarks. Calculated ILCRs are interpreted using the MDE risk benchmark (1×10^{-5}) for cumulative risk and USEPA's target cancer-risk range (1×10^{-4} to 1×10^{-6}); HIs are evaluated using a value of 1.0.

USEPA defines the range of 1×10^{-4} to 1×10^{-6} as the ILCR target range for hazardous waste facilities addressed under the federal Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and Resource Conservation and Recovery Act (RCRA). Individual or cumulative ILCRs greater than 1×10^{-4} are generally considered "unacceptable" by USEPA.

Risk management decisions are necessary when the ILCR is within 1×10^{-4} to 1×10^{-6}. USEPA typically does not require remediation when the cumulative ILCR is less than 1×10^{-6}. Similarly, cumulative ILCRs greater than 1×10^{-5} are generally considered "unacceptable" by MDE; remediation may or may not be necessary when the cumulative ILCR exceeds 1×10^{-5}.

An HI exceeding unity (1) indicates that noncarcinogenic health risks may be associated with exposure. If an HI exceeds unity, target-organ effects associated with exposure to COPC are considered. Only those HQs for chemicals affecting the same target organ(s) or exhibiting similar critical effect(s) are regarded as truly additive. Consequently, the cumulative HI could exceed 1, but no adverse health effects would be anticipated unless the COPC affect the same target organ or exhibit the same critical effect (i.e., unless target-organ-/critical-effect-specific HIs exceed 1).

As a general guideline, a "no further action" recommendation is forwarded to MDE whenever the cancer-risk estimates and total HIs (estimated on a target-organ/target-effect basis) for receptors of concern are less than 1×10^{-5} and 1, respectively. Otherwise, in most cases, the need for remedial action (including institutional controls) will be evaluated in a feasibility study (FS). However, the 1×10^{-5} risk benchmark should not be viewed as a discrete limit. Risks slightly greater than 1×10^{-5} may be considered regulatorily "acceptable" (i.e., a risk level deemed protective of human health) if justified by site-specific conditions, including any uncertainties about the nature and extent of contamination and associated risks. Consequently, a "no further action" recommendation may be forwarded to MDE risk managers for review and discussion when the 1×10^{-5} risk benchmark is exceeded. Those reviews and discussions may affect the analyses in the FS. The following factors were considered in making this determination:

- the magnitude of the environmental-medium-specific risk estimates
- significant uncertainties in the baseline HHRA that would overestimate baseline risk assessment results
- significant uncertainties in EPC estimates that would overestimate baseline risk assessment results

5.4.3 Risk Characterization Results

This section presents risk characterization results for COPC detected in soils and groundwater in each of the two EUs evaluated (i.e., RECs #9 and #10, and REC # 11). Potential risks from

direct-contact exposures to soil and groundwater, as well as a refined evaluation of the potential for chemical migration from soils to groundwater, are provided. Uncertainties associated with these risk estimates are discussed in Section 5.5. The methodology to calculate the risks presented in this section was discussed in Sections 5.2 and 5.3. Potential risks from direct-contact exposures to soil and groundwater are discussed in Sections 5.4.3.1 through 5.4.3.4. DRO and GRO are discussed in Section 5.4.3.5. Potential risks associated with vapor intrusion into buildings are discussed in Section 5.4.3.6. A refined evaluation of the potential for chemical migration from soils to groundwater is presented in Section 5.4.3.7.

Potential cancer risks and HIs were calculated for current and future construction workers; commercial/industrial workers; child and adolescent trespassers; child, adolescent, and adult recreational users; and hypothetical child, adolescent, and adult residents exposed to COPC across the GSP study area under the RME scenario; these results are summarized in Tables 5-30 and 5-35. Note that the worker receptors are the most relevant receptors evaluated in this HHRA. Risk estimates for the trespasser, recreational user, and hypothetical future resident are included primarily for completeness, and to support risk management decisions. In addition to the EU-specific risk estimates in Tables 5-30 and 5-35, cancer-risk estimates and hazard indices are presented on a location-by-location basis in Appendix J to help identify contaminant "hot spots" in the GSP study area.

Sample calculations are in Appendix J. The results of the risk assessment in the RAGS *Part D* format are in Appendix J. COPC-specific risk estimates and HIs developed to calculate the cumulative location-specific risks are in Appendix J.

5.4.3.1 Noncarcinogenic Hazards: RME—RECs #9 & #10

Tables 5-26 through 5-29 summarize the chemical concentrations detected in the REC #9 and #10 EU soil and groundwater samples. Cumulative HIs for the receptors hypothetically exposed to COPC in surface and subsurface soil in RECs #9 and #10 are summarized below. Chemicals contributing to target-organ-specific HIs greater than one are considered chemicals of concern (COC) and are listed by environmental medium in Table 5-30. These COC will be further evaluated in the FS for GSP. The "risk drivers" listed in the following table are the predominant COPC contributing to the medium-specific cumulative risk estimates:

Receptor	Environmental medium	Hazard index	Primary risk drivers[1]
Construction worker	Surface soil (SS)	8	SS: Mn
	Subsurface soil (SB)	0.3	SB: No COC[2]
	Groundwater (GW)	0.7	GW: No COC[2]
	Receptor total (SS + GW)	9	—
	Receptor total (SB + GW)	1	—
Industrial/commercial worker	Surface soil	0.3	SS: No COC[2]
	Subsurface soil	0.07	SB: No COC[2]
Child trespasser/visitor	Surface soil	0.6	SS: No COC[2]
	Subsurface soil	0.2	SB: No COC[2]
Adolescent trespasser/visitor	Surface soil	0.1	SS: No COC[2]
	Subsurface soil	0.04	SB: No COC[2]
Child recreational user	Surface soil	0.7	SS: No COC[2]
	Subsurface soil	0.3	SB: No COC[2]
Adolescent recreational user	Surface soil	0.1	SS: No COC[2]
	Subsurface soil	0.06	SB: No COC[2]
Adult recreational user	Surface soil	0.09	SS: No COC[2]
	Subsurface soil	0.04	SB: No COC[2]
Child resident	Surface soil	4	SS: Mn
	Subsurface soil	2	SB: No COC[2]
	Groundwater	90	GW: Co, Mn, TCE, As
	Receptor total (SS + GW)	93	—
	Receptor total (SB + GW)	91	—
Adolescent resident	Surface soil	0.7	SS: No COC[2]
	Subsurface soil	0.3	SB: No COC[2]
	Groundwater	66	GW: Co, Mn, TCE, As
	Receptor total (SS + GW)	66	—
	Receptor total (SB + GW)	66	—
Adult resident	Surface soil	0.4	SS: No COC[2]
	Subsurface soil	0.2	SB: No COC[2]
	Groundwater	53	GW: Co, TCE, As
	Receptor total (SS + GW)	53	—
	Receptor total (SB + GW)	53	—

[1]The following abbreviations are used: As: arsenic, Co: cobalt, Mn: manganese, TCE: trichloroethene.

[2]HIs calculated on a target-organ-specific basis do not exceed 1. Therefore, no COC were identified for this medium.

HIs calculated on a target-organ-specific basis do not exceed 1 for industrial workers, trespassers/visitors, or recreational users. Consequently, adverse noncarcinogenic health effects are not anticipated for these receptors under the conditions established in the exposure assessment.

HIs calculated on a target-organ-specific basis exceed 1 for construction workers and child residents exposed to COPC in surface soil; these exceedances are due primarily to manganese. For the construction worker, manganese contributes to the HI exceedance noted, primarily via the inhalation exposure-route. No HIs exceed 1 on a target-organ-specific basis for subsurface

soil. HIs for residents exposed to groundwater exceed 1; primary contributors to the exceedances are cobalt, trichloroethene, and arsenic for child, adolescent, and adult residents, and manganese for child and adolescent residents. Trichloroethene is the predominant contributor to the total HI for residential exposures to groundwater, as the HQ for trichloroethene in groundwater was 67, 48, and 43 for child, adolescent, and adult residents, respectively.

Risk estimates calculated on a location-specific basis are in Appendix J. None of the location-specific HIs calculated for the typical industrial worker exposed to COPC in surface soil or subsurface soils exceed 1. HIs calculated for the construction worker exceed 1 in four surface soil locations (maximum HI=8.5), but HIs do not exceed 1 in subsurface soil. HIs calculated for the hypothetical future resident for samples from seven surface soil locations (maximum HI=3.2) and six subsurface soil locations (maximum HI=2.4) exceed 1; metals are major risk contributors (e.g., manganese and thallium). For groundwater, HIs for residents exceed 1 in six of the seven wells evaluated, with a maximum HI of 68 at GSP-MW-07. Trichloroethene is the major contributor to the maximum HI.

5.4.3.2 Noncarcinogenic Hazards: RME—REC #11

Tables 5-31 through 5-34 summarize the chemical concentrations detected in REC #11 EU soil and groundwater samples. Cumulative HIs for the receptors hypothetically exposed to COPC in surface and subsurface soil in REC #11 are summarized below. Chemicals contributing to target-organ-specific HIs greater than one are considered COC and are listed by environmental medium in Table 5-35. These COC will be further evaluated in the FS for GSP. The "risk drivers" listed in the following table are the predominant COPC contributing to the medium-specific cumulative risk estimates:

Receptor	Environmental medium	Hazard index	Primary risk drivers[1]
Construction worker	Surface soil (SS)	2	SS: No COC[2]
	Subsurface soil (SB)	3	SB: Mn
	Groundwater (GW)	0.08	GW: No COC[2]
	Receptor total (SS + GW)	2	—
	Receptor total (SB + GW)	3	—
Industrial/commercial worker	Surface soil	0.1	SS: No COC[2]
	Subsurface soil	0.2	SB: No COC[2]
Child trespasser/visitor	Surface soil	0.3	SS: No COC[2]
	Subsurface soil	0.4	SB: No COC[2]
Adolescent trespasser/visitor	Surface soil	0.06	SS: No COC[2]
	Subsurface soil	0.08	SB: No COC[2]

Receptor	Environmental medium	Hazard index	Primary risk drivers[1]
Child recreational user	Surface soil	0.4	SS: No COC[2]
	Subsurface soil	0.5	SB: No COC[2]
Adolescent recreational user	Surface soil	0.08	SS: No COC[2]
	Subsurface soil	0.08	SB: No COC[2]
Adult recreational user	Surface soil	0.05	SS: No COC[2]
	Subsurface soil	0.06	SB: No COC[2]

[1]The following abbreviations are used: As: arsenic, Co: cobalt, Fe: iron, Mn: manganese, TCE: trichloroethene, Tl: thallium.

[2]HIs calculated on a target-organ-specific basis do not exceed 1. Therefore, no COC were identified for this medium.

Child resident	Surface soil	2	SS: No COC[2]
	Subsurface soil	3	SB: No COC[2]
	Groundwater	64	GW: Co, TCE, As, Fe, Tl
	Receptor total (SS + GW)	66	—
	Receptor total (SB + GW)	66	—
Adolescent resident	Surface soil	0.4	SS: No COC[1]
	Subsurface soil	0.5	SB: No COC[1]
	Groundwater	47	GW: Co, TCE, As, Tl
	Receptor total (SS + GW)	48	—
	Receptor total (SB + GW)	48	—
Adult resident	Surface soil	0.2	SS: No COC[2]
	Subsurface soil	0.3	SB: No COC[2]
	Groundwater	28	GW: Co, TCE, As, Tl
	Receptor total (SS + GW)	28	—
	Receptor total (SB + GW)	28	—

[1]The following abbreviations are used: As: arsenic, Co: cobalt, Fe: iron, Mn: manganese, TCE: trichloroethene, Tl: thallium.

[2]HIs calculated on a target-organ-specific basis do not exceed 1. Therefore, no COC were identified for this medium.

HIs calculated on a target-organ-specific basis do not exceed 1 for industrial workers, trespassers/visitors, or recreational users. Consequently, adverse noncarcinogenic health effects are not anticipated for these receptors under the conditions established in the exposure assessment.

HIs calculated on a target-organ-specific basis exceed 1 for construction workers exposed to COPC in surface soil; these exceedances are due primarily to manganese via the inhalation pathway. No other HIs exceed 1 on a target-organ-specific basis for surface or subsurface soil. HIs for child, adolescent, and adult residents exposed to groundwater exceed 1; primary contributors to the exceedances are cobalt, trichloroethene, arsenic, and thallium. Iron is a significant contributor only for the child resident.

Risk estimates calculated on a location-specific basis are in Appendix J. None of the location-specific HIs calculated for the typical industrial worker exposed to COPC in surface soil exceed 1, and only one subsurface soil sample slightly exceeds 1 (HI=1.5). HIs calculated for the construction worker exceed 1 in two surface soil samples (maximum HI=3.8) and two subsurface soil samples (maximum HI = 2.8). HIs calculated for the hypothetical future resident for samples from three surface soil locations (maximum HI=1.6) and five subsurface soil locations (maximum HI=3.7) exceed 1; metals (e.g., manganese, thallium) are the major contributors to risk. All of the seven wells evaluated have HIs that exceed 1 for residents exposed to COPC in groundwater. The maximum HI is 56 at GSP-SB-084. The temporary well at location GSP-SB-084 was noted as having some elevated metals concentrations (see Section 5.5).

5.4.3.3 Carcinogenic Risks: RME—RECs #9 & #10

Cancer-risk estimates for receptors hypothetically exposed to EPC for COPC in soil and groundwater samples in RECs #9 and #10 are summarized in the following table. Chemicals contributing an ILCR greater than 1×10^{-6} are listed in Table 5-30 by environmental medium. Chemicals are considered COC if the cumulative-risk estimate for the environmental medium exceeds 1×10^{-5}. RECs #9 and #10 COC will be further evaluated in the FS. The "risk drivers" in the following table are the predominant COPC contributing to the cancer-risk estimates presented here by medium:

Receptor	Environmental medium	Cancer-risk estimates	Primary risk drivers[1]
Construction worker	Surface soil (SS)	5×10^{-6}	SS: No COC[2]
	Subsurface soil (SB)	2×10^{-6}	SB: No COC[2]
	Groundwater	5×10^{-7}	GW: No COC[2]
	Receptor total (SS + GW)	6×10^{-6}	—
	Receptor total (SB + GW)	3×10^{-6}	—
Industrial/commercial worker	Surface soil	*3×10^{-5}*[3]	SS: BaPEq
	Subsurface soil	1×10^{-5}	SB: No COC[2]
Child trespasser/visitor	Surface soil	*7×10^{-5}*[3]	SS: BaPEq
	Subsurface soil	*2×10^{-5}*[3]	SB: BaPEq
Adolescent trespasser/visitor	Surface soil	1×10^{-5}	SS: No COC[2]
	Subsurface soil	4×10^{-6}	SB: No COC[2]
Lifelong recreational user	Surface soil	*1×10^{-4}*[3]	SS: BaPEq, As
	Subsurface soil	*3×10^{-5}*[3]	SB: BaPEq, As
Lifelong resident	Surface soil	**6×10^{-4}**[4]	SS: BaPEq, As
	Subsurface soil	**2×10^{-4}**[4]	SB: BaPEq, As, Aroclor-1260
	Groundwater	**1×10^{-3}**[4]	GW: TCE, As, Cr VI, benzene, c. tetrachloride

Receptor	Environmental medium	Cancer-risk estimates	Primary risk drivers[1]
	Receptor total (SS + GW)	**2×10^{-3}**[4]	—
	Receptor total (SB + GW)	**1×10^{-3}**[4]	—

[1] The following abbreviations are used: As: arsenic, BaPEq: benzo(a)pyrene equivalents, Cr VI: hexavalent chromium, c. tetrachloride: carbon tetrachloride, TCE: trichloroethene.

[2] ILCRs do not exceed 1×10^{-5}. Therefore, no COC were identified for this medium.

[3] The medium-specific ILCR exceeds 1×10^{-5} (ILCRs are italicized).

[4] The medium-specific ILCR exceeds 1×10^{-4} (ILCRs are bolded).

Cancer-risk estimates for the construction worker and adolescent trespassers do not exceed either USEPA or MDE cumulative cancer-risk benchmarks. Cumulative cancer-risk estimates for the lifelong resident exposed to EPC for COPC in surface soil (6×10^{-4}) and subsurface soil (2×10^{-4}) exceed the USEPA's target cancer-risk range as well as MDE's cumulative cancer-risk benchmark of 1×10^{-5}. Cumulative cancer-risk estimates for industrial workers exposed to COPC in surface soil, and child trespassers and lifelong recreational users exposed to COPC in surface and subsurface soil also exceed MDE's cumulative risk benchmark of 1×10^{-5}. The primary risk drivers for all these receptors are the BaPEq and, to a lesser extent, arsenic for recreational users and residents. Aroclor-1260 is a risk driver for lifelong residents exposed to COPC in subsurface soil.

The ILCR for the construction worker exposed to COPC in groundwater does not exceed USEPA's target cancer-risk range or MDE's cumulative risk benchmark. However, the ILCR for the lifelong resident exposed to COPC in groundwater exceeds USEPA's target cancer-risk range and MDE's cumulative-risk benchmark. The primary risk drivers are trichloroethene, arsenic, hexavalent chromium, and, to a lesser extent, benzene and carbon tetrachloride. As noted earlier, assuming all total chromium in groundwater is present in the hexavalent state is conservative. Consequently, ILCRs for chromium for groundwater may be overestimated.

Cancer-risk estimates calculated on a location-specific basis are in Appendix J. ILCRs for construction workers slightly exceed 1×10^{-5} at one location in surface soil and one location in subsurface soil (these ILCRs were 1.2×10^{-5} and 1.3×10^{-5}, respectively). Although location-specific risk estimates for the typical industrial worker exposed to COPC concentrations in surface and subsurface soils exceed 1×10^{-5} at a limited number of RECs #9 and #10 locations, none of the risk estimates exceed 1×10^{-4}. In contrast, risk estimates for the hypothetical future resident for several surface and subsurface soil locations exceed 1×10^{-4}. As noted above, BaPEq is the primary risk driver. For groundwater, hypothetical resident ILCRs exceed 1×10^{-4} in several

locations. Predominant risk drivers include arsenic, chromium (evaluated as hexavalent chromium), and trichloroethene.

5.4.3.4 Carcinogenic Risks: RME—REC #11

Cancer-risk estimates for receptors hypothetically exposed to EPC of COPC in soil and groundwater samples in REC #11 are summarized in the following table. Chemicals contributing an ILCR greater than 1×10^{-6} are listed in Table 5-35 by environmental medium. Chemicals are considered COC if the cumulative-risk estimate for the environmental medium exceeds 1×10^{-5}. COC will be further evaluated in the FS. The "risk drivers" in the following table are the predominant COPC contributing to the cancer-risk estimates presented here by medium:

Receptor	Environmental medium	Cancer-risk estimates	Primary risk drivers[1]
Construction worker	Surface soil (SS)	2×10^{-6}	SS: No COC[2]
	Subsurface soil (SB)	3×10^{-6}	SB: No COC[2]
	Groundwater (GW)	2×10^{-7}	GW: No COC[2]
	Receptor total (SS + GW)	2×10^{-6}	—
	Receptor total (SB + GW)	3×10^{-6}	—
Industrial/commercial worker	Surface soil	9×10^{-6}[2]	SS: No COC[2]
	Subsurface soil	1×10^{-5}[2]	SB: No COC[2]
Child trespasser/visitor	Surface soil	*2×10^{-5}*[3]	SS: BaPEq
	Subsurface soil	*3×10^{-5}*[3]	SB: BaPEq, As
Adolescent trespasser/visitor	Surface soil	4×10^{-6}	SS: No COC[2]
	Subsurface soil	6×10^{-6}	SB: No COC[2]
Lifelong recreational user	Surface soil	*3×10^{-5}*[3]	SS: BaPEq, Aroclor-1260, As
	Subsurface soil	*4×10^{-5}*[3]	SB: BaPEq, As
Lifelong resident	Surface soil	*1×10^{-4}*[3]	SS: BaPEq, n-nitroso-di-n-propylamine, Aroclor-1260, As
	Subsurface soil	**2×10^{-4}**[4]	SB: BaPEq, As, Aroclor-1260
	Groundwater	**7×10^{-4}**[4]	GW: Cr VI, TCE, VC, As
	Receptor total (SS + GW)	**8×10^{-4}**[4]	—
	Receptor total (SB + GW)	**9×10^{-4}**[4]	—

[1] The following abbreviations are used: As: arsenic, BaPEq: benzo(a)pyrene equivalents, Cr VI: hexavalent chromium, TCE: trichloroethene, VC: vinyl chloride.

[2] ILCRs do not exceed 1×10^{-5}. Therefore, no COC were identified for this medium.

[3] The medium-specific ILCR exceeds 1×10^{-5} (ILCRs are italicized).

[4] The medium-specific ILCR exceeds 1×10^{-4} (ILCRs are bolded).

Cancer-risk estimates for the construction worker, industrial worker, and adolescent trespasser do not exceed either USEPA or MDE cumulative cancer-risk benchmarks for soil or groundwater.

Cumulative cancer-risk estimates for the lifelong resident exposed to EPC for COPC in subsurface soil and groundwater exceed the USEPA's target cancer-risk range and MDE's cumulative risk benchmark of 1×10^{-5}. Lifelong residents exposed to COPC in surface soil and child trespassers and lifelong recreational users exposed to COPC in surface and subsurface soil also exceed MDE's cumulative-risk benchmark of 1×10^{-5}.

The primary risk drivers for cancer-risk exceedances are the BaPEq in surface and subsurface soil, and, in some cases, but to a lesser extent, arsenic and Aroclor-1260. The SVOC n-nitroso-di-n-propylamine is also a lesser risk driver for the lifelong resident exposed to surface soil; however, this compound was detected in only one of 32 REC #11 surface soil samples. The primary risk drivers for residential exposure to COPC in groundwater are trichloroethene, vinyl chloride, hexavalent chromium, and arsenic. However, as noted earlier, assuming all total chromium in groundwater is present in the hexavalent state is conservative. Consequently, ILCRs for chromium in groundwater may be overestimated.

Cancer-risk estimates calculated on a location-specific basis are in Appendix J. No surface or subsurface soil locations have ILCRs that exceed 1×10^{-5} for the construction worker. Although location-specific risk estimates for the typical industrial worker exposed to COPC concentrations in surface and subsurface soil exceed 1×10^{-5} at a limited number of REC #11 locations, none of the risk estimates exceed 1×10^{-4}. In contrast, risk estimates for the hypothetical future resident for several locations in REC #11 exceed 1×10^{-4}. As noted above, BaPEq is the primary risk driver. In groundwater, ILCRs for residents exceed 1×10^{-4} in six of the seven wells evaluated. Primary risk drivers include arsenic, chromium (evaluated as hexavalent chromium), trichloroethene, and vinyl chloride.

5.4.3.5 GRO/DRO

Risk estimates and HIs could not be developed for DRO and GRO due to a lack of toxicity criteria. DRO was selected as a COPC for surface soil, subsurface soil, and groundwater. Maximum detected DRO concentrations in surface and subsurface soil exceed the MDE residential-soil cleanup criterion of 230 mg/kg and the non-residential-soil cleanup criterion of 620 mg/kg in both RECs #9 and #10 and REC #11. DRO concentrations in groundwater also exceed the MDE groundwater cleanup criterion of 47 µg/L. GRO was selected as a COPC in groundwater only. GRO concentrations exceed the MDE cleanup criterion of 47 µg/L in

RECs #9 and #10, but do not exceed it in REC #11. GRO and DRO are evaluated in more detail in Section 5.5.

5.4.3.6 Vapor Intrusion

As discussed in Section 5.1, several VOCs were detected in groundwater samples at concentrations exceeding USEPA screening levels for VOC migration from groundwater to soil gas (and subsequently through building foundations into the interior air). USEPA's Johnson and Ettinger volatilization model (2004b) was not used to evaluate risks to hypothetical future residents and industrial workers potentially exposed to these COPC because of the significant uncertainty related to using that model to estimate indoor air concentrations from groundwater. Instead, a qualitative evaluation of the vapor intrusion COPC for each site is presented in this section. Note that the analysis presented is only for hypothetical future structures. No structures exist in or downgradient of the REC #9 and #10 or REC #11 study areas. The following chemicals were detected in all groundwater samples at concentrations exceeding residential screening-criteria for vapor intrusion: benzene, carbon tetrachloride, chloroform, trichloroethene, and vinyl chloride.

RECs #9 and #10—The following table compares the maximum concentrations (which were also used as the EPC) of the "global" COPC to the vapor-intrusion screening levels:

Global chemical of potential concern	Maximum concentration (µg/l)	Residential groundwater volatilization criterion (µg/l)
Benzene	3.1	1.4 C
Carbon tetrachloride	2.6	0.36 C
Chloroform	0.92	0.73 C
Trichloroethene	450	0.52 N
Vinyl chloride	Not detected	0.14 C

C: carcinogen

N: noncarcinogen

The screening criteria for carcinogens are based on an ILCR of 1×10^{-6}. Vinyl chloride has not been detected in RECs #9 and #10. Concentrations of benzene, carbon tetrachloride, and chloroform exceed the screening criteria by less than one order of magnitude, indicating that cancer risks for these COPC would be less 1×10^{-5} and therefore would not (individually) exceed MDE's target cancer-risk level. The screening level for trichloroethene is based on an HQ of 0.1.

The maximum concentration of trichloroethene also exceeds the screening level based on an HQ of 1. However, trichloroethene has only been detected in two of 10 groundwater samples collected from RECs #9 and #10. The maximum concentration (used as the EPC) was 450 µg/L (detected in MW-07 screened at 12–22 feet bgs), but the second greatest detection is only 0.27 µg/L, which is considerably less. If 0.27 µg/L had been used as the EPC, trichloroethene would not exceed the screening level. However, the maximum concentration of trichloroethene detected in groundwater could potentially pose risks to receptors via the indoor air pathway, specifically at location MW-07. Note that the table above presents residential criteria. Industrial exposures to vapor-intrusion COPC are expected to be less intense and less frequent than residential exposures.

REC# 11—The following table compares the maximum concentrations (which were also used as the EPC) of the "global" COPC to the vapor-intrusion screening levels:

Global chemical of potential concern	Maximum concentration (µg/l)	Residential groundwater volatilization criterion (µg/l)
Benzene	0.31	1.4 C
Carbon tetrachloride	Not detected	0.36 C
Chloroform	Not detected	0.73 C
Trichloroethene	25	0.52 N
Vinyl chloride	0.66	0.14 C

C: carcinogen
N: noncarcinogen

Screening criteria for carcinogens are based on an ILCR of 1×10^{-6}. Carbon tetrachloride and chloroform have not been detected in REC #11. The maximum concentration of benzene in REC #11 does not exceed the screening level. The maximum concentration of vinyl chloride exceeds screening criteria by less than one order of magnitude, indicating that cancer risks for this COPC would be less 1×10^{-5} and therefore would not exceed MDE's target cancer-risk level. The screening level for trichloroethene is based on an HQ of 0.1. The maximum concentration of trichloroethene also exceeds the screening level based on an HQ of 1.

Trichloroethene concentrations detected in three of the seven wells (i.e., MW-01, MW-04, and GSP-SB-089) in REC #11 have a maximum concentration exceeding the screening level based on an HQ of 1. Therefore, trichloroethene in groundwater could potentially pose risks to

receptors via the indoor air pathway at these REC #11 locations. Note that the table above presents residential criteria. Industrial exposures to vapor-intrusion COPC are expected to be less intense and less frequent than residential exposures.

5.4.3.7 Refined Evaluation of Chemical Migration from Soils to Groundwater

COPC for migration from soils to groundwater were selected as described in Section 5.1. However, a more refined evaluation of the potential for such migration is included in this section based on the following considerations:

- Does the maximum-detected soil concentration exceed the groundwater-protection screening-criterion at a DAF of 20?
- Does the mean of positive detections in soil exceed the groundwater-protection screening-criterion at a DAF of 20?
- What is the frequency of detections exceeding the groundwater-protection screening-criterion at a DAF of 20?
- Was the chemical selected as a COPC in groundwater?
- Does the maximum concentration in groundwater exceed the federal SDWA MCL?
- What is the frequency of detections in groundwater exceeding the MDE screening level for groundwater or the USEPA RSL for tap water (based on an ILCR of 1×10^{-6} or an HI of 1)?
- What is the frequency of detections in groundwater exceeding 10 times the USEPA RSL for tap water (based on an ILCR of 1×10^{-6} or an HI of 1)?

These factors are considered when selecting COC for groundwater protection. Chemicals selected as COPC for migration from soil to groundwater in the initial screening were not retained as COC if any of the following was true:

- The maximum soil concentration is less than the groundwater-protection criterion based on a DAF of 20.

  ***Rationale*:** As mentioned previously, a DAF of 1 is conservative; a DAF of 20 is assumed more accurate at most sites. Note that the MDE groundwater-protection criteria are based on a DAF of 20 and the USEPA SSLs for groundwater protection are based on a DAF of 1. The USEPA SSLs were adjusted (i.e., multiplied by 20) for this evaluation.

- The frequency of detections greater than the groundwater-protection screening-criterion at a DAF of 20 is less than 5% (when at least 20 samples are included in the data set and

no potential contamination "hot spot" is present). A potential "hot spot" is defined as a concentration that exceeds twice the screening criterion at a DAF of 20.

***Rationale*:** Chemicals are unlikely to pose risks to water quality through leaching from soil to groundwater if they are detected infrequently (i.e., less than 5%) in soil.

- The chemical was not selected as a COPC in groundwater.

  ***Rationale*:** If a chemical was not selected as a COPC in site groundwater, the data do not indicate that water quality has been adversely affected. This is an important consideration, because the contamination events in the study area are presumed to have occurred more than 20 years ago. Thus, given the passage of time, groundwater concentrations likely reflect the potential for chemical migration from soils to groundwater.

- The maximum concentration in groundwater is less than the SDWA MCL.

  ***Rationale*:** SDWA MCLs are federally enforceable drinking-water standards. Concentrations of chemicals in groundwater less than their corresponding SDWA MCLs indicate that groundwater has not been adversely affected.

- The frequency of detections greater than the MDE groundwater screening-level or the USEPA tap water RSL is less than 5% (when at least 20 samples are included in the data set and no potential contamination "hot spot" is present). A potential "hot spot" is defined as a concentration twice the MDE groundwater screening-level or USEPA tap water RSL.

  ***Rationale*:** Chemicals are unlikely to pose risks to water quality through leaching from soil to groundwater if they are detected infrequently (i.e., less than 5%) in groundwater.

Less than 20 groundwater samples were available for each EU. Therefore, no chemicals were eliminated as COC for groundwater protection based on the frequency of detections greater than the direct-contact screening level for groundwater.

EU-specific comparisons of soil data to MDE groundwater-protection criteria and adjusted USEPA SSLs for groundwater protection are included in the Occurrence and Distribution of Chemicals tables for surface soil and subsurface soil (Tables 5-26, 5-27, 5-31, 5-32). EU-specific comparisons of groundwater data to MDE groundwater cleanup standards and USEPA RSLs for tap water are included in the Occurrence and Distribution of Chemicals tables for groundwater (Tables 5-29 and 5-34).

Filtered-groundwater metals results were evaluated instead of total metals results because total (unfiltered) metals results can be artificially elevated as a consequence of high sample-turbidity often observed in unfiltered samples. However, in most cases, metals results appear similar

between the filtered and total metals fractions. Thus, the evaluation of filtered groundwater results (versus unfiltered metals results) does not greatly affect overall conclusions.

The global COPC selected in Section 5.1 for the migration to groundwater pathway are:

Surface soil:

- *VOCs:* 1,2,4-trichlorobenzene, 1,3-dichlorobenzene, benzene, methylene chloride, naphthalene, and trichloroethene

- *SVOCs:* 2-methylnaphthalene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, bis(2-ethylhexyl)phthalate, butyl benzyl phthalate, carbazole, chrysene, dibenzo(a,h)anthracene, dibenzofuran, indeno(1,2,3-cd)pyrene, naphthalene, n-nitroso-di-n-propylamine, phenanthrene, and pyrene

- *PCBs:* Aroclor-1260 and total Aroclor

- *Metals:* antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, selenium, and thallium

Subsurface soil:

- *VOCs:* 1,2,3-trimethylbenzene, 1,2,4-trimethylbenzene, benzene, ethylbenzene, m+p-xylenes, methylene chloride, naphthalene, o-xylene, total xylenes, trichloroethene, and vinyl chloride

- *SVOCs:* 1,1-biphenyl, 2-methylnaphthalene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, bis(2-ethylhexyl)phthalate, carbazole, chrysene, dibenzo(a,h)anthracene, dibenzofuran, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, and pyrene

- *PCBs:* Aroclor-1242, Aroclor-1260, and total Aroclor

- *Metals:* antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, thallium, and vanadium

Note that none of the PAHs or other SVOCs selected as migration to groundwater COPC were detected in the groundwater samples except for bis(2-ethylhexyl)phthalate and butyl benzyl phthalate. Therefore, PAHs and SVOCs other than bis(2-ethylhexyl)phthalate and butyl benzyl phthalate are not retained as COC for the migration from soil to groundwater pathway and are not discussed further in this section. PCBs were not target analytes for the groundwater samples. Therefore, PCBs were evaluated using only the available soil data.

RECs #9 and #10 surface soil—The "global" groundwater protection COPC methylene chloride, naphthalene, bis(2-ethylhexyl)phthalate, Aroclor-1260, and all the metals COPC were detected in RECs #9 and #10 surface soil. Methylene chloride, naphthalene, bis(2-ethylhexyl)phthalate, Aroclor-1260, antimony, barium, cadmium, copper, lead, mercury, and selenium were not detected in surface soil at concentrations exceeding their respective MDE groundwater-protection criteria or the USEPA SSL at a DAF of 20. They are therefore eliminated as COC.

Reported concentrations of arsenic, chromium (screened against criteria for hexavalent chromium), cobalt, iron, manganese, and thallium do exceed their respective groundwater protection criteria developed using a DAF of 20. Thallium has not been detected in RECs #9 and #10 groundwater and therefore is not retained as a COC. Conversely, arsenic, chromium, cobalt, iron, and manganese have also been detected in filtered groundwater in RECs #9 and #10 at concentrations exceeding MDE or USEPA direct-contact screening levels. However, arsenic concentrations in groundwater are less than the MCL; therefore, arsenic is not retained as a COC for migration to groundwater. Chromium concentrations in groundwater are also less than the MCL for total chromium. For the purposes of risk characterization, 100% of total chromium in groundwater was assumed to be in the hexavalent state; however, this is very unlikely. Iron and manganese concentrations in groundwater exceed the MDE cleanup standard but do not exceed the tap water RSL.

Summary/conclusions for RECs #9 and #10 surface soil—The analysis presented above suggests that chromium, cobalt, iron, and manganese should be retained as migration to groundwater COC. Total chromium concentrations in groundwater are less than the MCL. Iron and manganese concentrations in groundwater are also less than the tap water RSL. Note that most of the chromium, cobalt, iron, and manganese concentrations detected in surface soil may reflect background conditions. (See Section 5.5.1 for further discussion of background soil concentrations.) Consequently, these parameters are not recommended for further evaluation.

RECs #9 and #10 subsurface soil—All VOC COPC except for vinyl chloride have been detected in RECs #9 and #10 subsurface soil. Aroclor-1260 and all metals COPC have also been detected in RECs #9 and #10 subsurface soil. Of the volatiles, detections of benzene, m+p-xylenes, methylene chloride, o-xylene, and total xylenes in soil do not exceed MDE criteria or USEPA criteria based on a DAF of 20, so they are eliminated from COC selection.

Concentrations of 1,2,3-trimethylbenzene and 1,2,4-trimethylbenzene exceed the SSL based on a DAF 20 in one of 31 samples. However, the maximum concentrations of these compounds are greater than twice the SSLs at a DAF of 20. 1,2,3-Trimethylbenzene, 1,2,4-trimethylbenzene, ethylbenzene, and naphthalene have not been detected in groundwater in RECs #9 and #10, so these chemicals are not retained as COC.

Trichloroethene was detected in two of 31 subsurface soil samples at a maximum concentration that exceeds the SSL at a DAF of 20. Trichloroethene has been detected in groundwater in RECs #9 and #10 at a maximum concentration that exceeds direct-contact criteria and the MCL. Trichloroethene is therefore retained as a COC.

Reported detections of bis(2-ethylhexyl)phthalate, Aroclor-1260, antimony, barium, cadmium, copper, iron, lead, manganese, mercury, nickel, selenium, and vanadium in subsurface soil do not exceed groundwater protection criteria based on a DAF of 20, so these chemicals are not retained as COC. The metals arsenic, chromium (evaluated using hexavalent criteria), cobalt, and thallium exceed groundwater protection criteria based on a DAF of 20 in more than 5% of samples. Thallium has not been detected in groundwater in RECs #9 and #10 and therefore is not retained as a COC. Arsenic, chromium, and cobalt have been detected in filtered groundwater at concentrations exceeding direct-contact screening criteria. However, concentrations of arsenic in groundwater are less than the MCL. Concentrations of chromium are less than the total chromium MCL. Although 100% of chromium in groundwater was assumed to be in the hexavalent state, this assumption is very conservative. No MCL is available for cobalt.

Summary/conclusions for RECs #9 and #10 subsurface soil—The analysis above suggests retaining trichloroethene, chromium, and cobalt as migration to groundwater COC. However, chromium concentrations in groundwater are less than the MCL for total chromium. Note that most of the chromium and cobalt concentrations detected in subsurface soil likely reflect background conditions. (See Section 5.5.1 for further discussion of background soil concentrations.) Consequently, chromium and cobalt are not recommended for further evaluation. Trichloroethene is recommended for further evaluation.

REC #11 surface soil—All of the "global" migration to groundwater COPC for surface soil except for methylene chloride have been detected in REC #11 surface soil. However, reported

detections for 1,2,4-trichlorobenzene, 1,3-dichlorobenzene, benzene, bis(2-ethylhexyl)phthalate, butyl benzyl phthalate, antimony, barium, cadmium, copper, lead, mercury, and selenium do not exceed groundwater protection criteria based on a DAF of 20. These chemicals are therefore not retained as COC. The VOCs naphthalene and trichloroethene exceed groundwater protection criteria based on a DAF of 20 in one of 33 samples and two of 33 samples, respectively. Napthalene exceeds the USEPA SSL at a DAF of 20, but not the MDE groundwater-protection cleanup level. Trichloroethene also exceeds the MDE groundwater-protection cleanup-level.

The maximum concentration of each of these VOCs is greater than two times the respective criterion. However, naphthalene has not been detected in REC #11 groundwater, so naphthalene is not retained as a COC. TCE was detected in eight of 10 groundwater samples at a maximum concentration exceeding direct-contact screening criteria, and has also been found at concentrations exceeding the MCL. TCE is therefore retained as a COC.

Aroclor-1260 subsurface soil concentrations exceed the USEPA SSL at a DAF of 20 in nine of 33 samples. Total Aroclor-also exceeds the USEPA SSL in nine of 33 samples. No groundwater data are available for PCBs; therefore, PCBs were evaluated solely on the basis of soil data.

Thallium concentrations exceed the USEPA SSL at a DAF of 20 in only one of 33 samples. The maximum concentration of thallium is less than two times the SSLs at a DAF of 20, so thallium is not retained as a COC. Concentrations of arsenic, chromium, cobalt, iron, and manganese in filtered groundwater exceed direct-contact screening criteria. However, the maximum concentration of arsenic is less than the MCL. Thus, arsenic is not retained as a COC.

Concentrations of chromium in groundwater exceed the hexavalent chromium direct-contact criterion. However, it is unlikely that all chromium in groundwater is present in the hexavalent state. Chromium concentrations in groundwater are less than direct-contact criterion for trivalent chromium and are less than the MCL for total chromium. No MCLs are available for cobalt, iron, and manganese. Concentrations of iron and manganese in groundwater exceed the MDE groundwater-cleanup standards but do not exceed the USEPA tap water RSL, based on an HI of 1.

Summary/conclusions for REC #11 surface soil—The preceding analysis suggests retaining the following chemicals as COC: trichloroethene, Aroclor-1260 and total Aroclor, chromium, cobalt, iron, and manganese. However, PCBs (i.e., the Aroclors) have already been identified as COC in

REC #11 surface soils because of direct-contact risk. In most cases, PCB parameters do not readily migrate from soils to groundwater, and direct-contact-risk remedial goals established for these chemicals are typically more conservative (i.e., lower than, more protective than) site-specific migration-to-groundwater remedial goals that may be calculated for these parameters.

Note that most of the chromium, cobalt, iron, and manganese concentrations detected likely reflect background conditions. (See Section 5.5.1 for further discussion of background soil concentrations.) Concentrations of iron and manganese in groundwater are also less than USEPA tap water RSLs. Chromium concentrations in groundwater are less than the direct-contact criterion for trivalent chromium and less than the MCL for total chromium. Consequently, the Aroclors, chromium, cobalt, iron, and manganese are not recommended for further evaluation. In contrast, trichloroethene is recommended for further evaluation.

REC #11 subsurface soil—All of the migration-to-groundwater "global" COPC have been detected in REC #11 subsurface soil except for benzene and methylene chloride. However, 1,2,3-trimethylbenzene, 1,2,4-trimethylbenzene, ethylbenzene, m+p-xylenes, o-xylene, total xylenes, bis(2-ethylhexyl)phthalate, antimony, barium, cadmium, copper, lead, mercury, nickel, selenium, and vanadium have not been detected in subsurface soil at concentrations exceeding groundwater protection criteria at a DAF of 20. These parameters are therefore not retained as COC.

Naphthalene exceeds the MDE groundwater-protection cleanup criterion and the USEPA SSL at a DAF of 20 in three of 27 samples and 11 of 27 samples, respectively. However, naphthalene has not been detected in REC #11 groundwater. Thus, naphthalene is not retained as a COC. Trichloroethene exceeds the groundwater protection criteria based on a DAF of 20 in more than 5% of samples. Trichloroethene was selected as a COPC in groundwater, and trichloroethene concentrations in REC #11 groundwater exceed the MCL. Therefore, trichloroethene is retained as a COC.

Only one concentration of vinyl chloride in subsurface soil exceeds both the MDE groundwater-protection cleanup standard and the USEPA SSL based on a DAF of 20; however, the maximum vinyl chloride concentration is greater than two times these criteria. Vinyl chloride concentrations in groundwater are less than the MCL. Vinyl chloride is thus not retained as a COC.

The PCBs Aroclor-1242 and Aroclor-1260 exceed the USEPA SSL based on a DAF of 20 in only one of 27 samples each. Similarly, total Aroclor-concentrations exceed the MDE groundwater protection cleanup standard in one of 27 samples. The maximum concentration of Aroclor-1242 is less than two times the relevant criterion; however, the maximum concentration of Aroclor-1260 is greater than two times the criterion. No groundwater data are available for PCBs; therefore, PCBs are evaluated on the basis of available soil data.

The metals arsenic, chromium, cobalt, iron, and manganese have subsurface soil concentrations exceeding the relevant groundwater protection criteria based on a DAF of 20. Concentrations of these metals in groundwater also exceed the applicable direct-contact criteria in most samples. However, the maximum concentration of arsenic in filtered groundwater is less than the MCL. Therefore, arsenic is not retained as a COC. It is very unlikely that 100% of total chromium is present in the hexavalent state in groundwater, and the maximum concentration of chromium in groundwater is less than the MCL for total chromium.

Iron concentrations in groundwater exceed the MDE groundwater cleanup standard in all three samples but only exceed the USEPA tap water RSL (based on an HQ of 1) in one of three samples. Manganese concentrations in groundwater exceed the MDE groundwater cleanup standard in two of three samples but do not exceed the USEPA tap water RSL (based on an HQ of 1). Thallium concentrations exceed the USEPA SSL at a DAF of 20 in three of 27 samples. However, the maximum concentration of thallium in REC #11 groundwater is less than the MCL. Therefore, thallium is not retained as a COC.

Summary/conclusions for REC #11 subsurface soil—The preceding analysis supports retaining the following chemicals as migration-to-groundwater COC: trichloroethene, Aroclor-1260, total Aroclor, chromium, cobalt, iron, and manganese. The narrative above regarding PCB detections in REC #11 surface soils also applies to REC #11 subsurface soils. Therefore, PCBs are not recommended for further evaluation based on groundwater protection. Note that most of the chromium, cobalt, iron, and manganese concentrations detected likely reflect background conditions. (See Section 5.1 for further discussion of background soil concentrations.) Consequently, chromium, cobalt, iron, and manganese are not recommended for further evaluation. Trichloroethene is recommended for further evaluation.

5.5 UNCERTAINTY ANALYSIS

The uncertainty analysis component of this HHRA summarizes uncertainties inherent in the risk assessment and includes a discussion of how they may affect the quantitative risk estimates and risk analysis conclusions. The baseline HHRA for the study area was done in accordance with current USEPA guidance. However, varying degrees of uncertainty are associated with any baseline HHRA. A brief discussion of uncertainty issues that must generally be considered in an HHRA is provided in the following narrative.

Uncertainty in selecting COPC is related to the status of the available databases, the grouping of samples, the numbers, types, and distributions of samples, data quality, and the procedures used to include or exclude constituents as COPC. Uncertainty associated with the exposure assessment can stem from the values used as input variables for a given intake route or scenario, the assumptions made to determine EPCs, and the predictions made regarding future land uses and population characteristics. Uncertainty in the toxicity assessment stems from the quality of the existing toxicity data needed to support dose-response relationships and the weight of evidence used to determine the carcinogenicity of COPC. Uncertainty in risk characterization is associated with receptor exposure to multiple chemicals and the cumulative uncertainty arising from combining conservative assumptions made in earlier steps of the risk assessment.

Whereas various sources of random uncertainty and bias exist, the magnitude of bias and uncertainty and the direction of bias are influenced by the assumptions made throughout the risk assessment, including selection of COPC, and of values for dose-response relationships. Throughout the risk assessment, assumptions that consider safety factors must be made to overestimate the final calculated risks. Risk assessments generally carry two types of uncertainty: *measurement* and *informational* uncertainty.

Measurement uncertainty refers to the usual variance that accompanies scientific measurements. For example, this type of uncertainty is associated with the analytical data collected for each site. The risk assessment reflects the accumulated variances of the individual values used.

Informational uncertainty stems from inadequate availability of information needed to complete the toxicity and exposure assessments. This gap is often significant, such as the absence of information on the effects of human exposure to low doses of a chemical, the biological

mechanism of chemical action, or the behavior of a chemical in soil. After the risk assessment is complete, the results must be reviewed and evaluated to identify the type and magnitude of uncertainty involved. Relying on risk assessment results without considering the uncertainties, limitations, and assumptions inherent in the process can be misleading. For example, to account for uncertainties in developing exposure assumptions, conservative estimates must be made to ensure that the particular assumptions protect sensitive subpopulations or maximally exposed individuals.

If a number of conservative assumptions are combined in an exposure model, the resulting calculations can propagate the uncertainties associated with those assumptions, thereby producing much larger uncertainty in the results. This uncertainty is biased toward overestimating both carcinogenic and noncarcinogenic risks. Thus, both the results of the risk assessment and the uncertainties associated with them must be considered when making risk management decisions.

This interpretation of uncertainty is especially relevant when the risks exceed the point of departure for defining "acceptable" risk. For example, when risks calculated using a high degree of uncertainty are less than a regulatorily "acceptable" risk level (i.e., 10^{-6}), the interpretation of "no significant risk" is typically straightforward. However, when risks calculated with a high degree of uncertainty exceed a regulatorily acceptable risk level (i.e., 10^{-4}), reaching a conclusion can be difficult unless uncertainty is considered. This HHRA was prepared using the November 2011 RSLs. However, the RSLs are "evergreen" screening values, subject to change as new toxicity information becomes available and is evaluated by USEPA. Consequently, the COPC could change in the future if the RSLs change.

5.5.1 Uncertainty in COPC Selection

The most significant issues related to uncertainty in COPC selection at the subject GSP RECs are the usability of existing databases (only validated data were used in the risk assessment), the COPC screening levels used, and the absence of screening levels for a few chemicals detected in site environmental media. A brief discussion of each of these issues is provided in the remainder of this section.

Usability and completeness of existing databases—As discussed in Section 5.1, data from samples collected in field investigations in 2010 and 2011 were used to assess risks to potential human receptors from exposure to contaminated environmental media. These data were validated according to USEPA data-validation guidelines. Only fixed-base analytical results (i.e., results from a fixed-base laboratory, as opposed to field analytical results) from the field investigations for the lists of target analytes were used in the quantitative risk evaluation. Data regarded as rejected (i.e., qualified as "R" during data validation) were not used in the quantitative risk assessment. Eliminating data qualified as "R" may increase uncertainty in the risk assessment.

As noted in Section 5.4, several metals in groundwater at REC #11 are risk drivers for residential receptors. Therefore, note that analytical results for several metals detected in groundwater samples collected from temporary well GSP-SB-084 (at REC #11) are somewhat anomalous. The total (unfiltered) concentrations of cobalt, nickel, and zinc detected in groundwater samples from both rounds of sampling exceed detected concentrations in most other wells by approximately one order of magnitude or more. This well is also the only well in which thallium has been detected. A comparison of filtered metals results to total metals results (for other metals) does not indicate that sample turbidity is an issue for this well. However, note the elevated metals concentrations in this well, because cobalt and thallium are primary risk drivers for REC #11 groundwater.

Naphthalene results were analyzed and reported in both the VOC and SVOC fractions. Both the VOC and SVOC naphthalene results were included in selecting COPC. For subsurface soil, naphthalene was selected as a direct-contact COPC in both the VOC and SVOC fractions. For EPCs in the quantitative risk assessment, the maximum EPC of naphthalene from either the VOC or the SVOC fractions was used for each EU. In subsurface soil, the maximum EPC for naphthalene is from the VOC fraction for RECs #9 and #10 and from the SVOC fraction for REC #11. Using the higher concentration ensures that risks due to naphthalene are not underestimated.

Soil samples collected from 0–15 feet bgs were included in the quantitative risk evaluation. Data for soil samples collected at depths greater than 15 feet bgs (i.e., deep subsurface soil) were excluded from the quantitative risk assessment because these samples are likely saturated; however, COPC were selected for informational purposes. Table 5-11 displays the results of the

COPC selection for deep subsurface soil. The list of COPC is similar to those for surface soil and shallower subsurface soil. COPC in deep subsurface soils are trichloroethene, BaPEq and its constituents, arsenic, chromium (if evaluated using hexavalent chromium screening criteria), cobalt, copper, thallium, vanadium, and DRO.

Maximum concentrations of all of these chemicals (except for trichloroethene and cobalt) are greater in the shallower depths than in the deep subsurface soil; concentrations of trichloroethene and cobalt in deep subsurface soil are not significantly greater than (i.e., they are within one order of magnitude of) those found in shallower soil depths. Thus, excluding deep subsurface soil from the quantitative risk evaluation is not a significant source of uncertainty.

Tentatively identified compounds—Several tentatively identified compounds (TICs) have been found in the VOC fractions of study area media (see detected concentrations tables in Appendix H and data-validation reports in Appendix I). (Validation reports will be included in the full report). Eight TICs were detected in surface soil, 22 TICs were detected in subsurface soil, and five TICs were detected in groundwater. These TICs were not evaluated. The presence of TICs does add some uncertainty to the risk assessment; however, we do not expect that chemicals excluded from the target analyte list would be major risk contributors at the study area.

COPC screening levels—By using risk-based screening values based on conservative land use scenarios (i.e., residential land use for soil), corresponding to ILCRs of 10^{-6} and HIs of 0.1, the risk analyst ensures that all significant contributors to risk at a site are evaluated. Eliminating chemicals present at concentrations that correspond to ILCRs less than 10^{-6} and HIs less than 0.1 should not affect the risk assessment's final conclusions, because those chemicals are not expected to pose potential health concerns at the concentrations detected.

Background soil database—Comprehensive site-specific background-soil databases are not available for the subject RECs. The lack of site-specific background levels for various chemicals may overestimate site-related risks for the RECs evaluated, since no chemical was eliminated as a COPC based on a background screen (i.e., a comparison of site concentrations to site-specific background concentrations). The lack of such data may also affect the selection of remedial goals for inorganics typically detected at background concentrations above common risk benchmarks (e.g., arsenic). Arsenic was noted as a risk driver in soil for several receptors and in several data

sets. Arsenic was noted in Section 5.4 as a risk driver for direct-contact risk posed to several receptors in both EUs evaluated, and manganese was noted as a risk driver for two receptors in RECs #9 and #10 for surface soil. Cancer-risk estimates based on arsenic concentrations in surface and subsurface soil are less than 1×10^{-5} for most receptors/data sets, except in the REC #11 subsurface soil data set for child and lifelong residents. Arsenic and manganese are metals occurring naturally in soil.

Anticipated typical concentrations (ATCs) are available from the State of Maryland for arsenic and manganese in soil (State of Maryland, 2008) for eastern, central, and western Maryland. MSA is in the eastern Maryland geological province as defined by the Maryland guidance (State of Maryland, June 2008). ATCs for arsenic are 3.6 mg/kg, 4.9 mg/kg, and 11 mg/kg for eastern, central, and western Maryland, respectively. EPCs (i.e., the 95% UCLs, 2.9 mg/kg for RECs #9 and #10, and 3.3 mg/kg for REC #11) calculated for arsenic in surface soil do not exceed the eastern Maryland ATC for either EU evaluated. The 95% UCL for arsenic in RECs #9 and #10 subsurface soil (3.8 mg/kg) slightly exceeds the eastern Maryland ATC. The 95% UCL for arsenic in REC #11 subsurface soil (11.9 mg/kg) exceeds the eastern Maryland ATC and slightly exceeds the western Maryland ATC. The maximum concentration of arsenic in REC #11 subsurface soil is 52 mg/kg, which is approximately one order of magnitude greater than the next greatest concentration in this data set (5.8 mg/kg).

ATCs for manganese are 480 mg/kg, 1,400 mg/kg, and 1,500 mg/kg for eastern, central, and western Maryland, respectively. The EPC for manganese in RECs #9 and #10 surface soil (i.e., 2,200 mg/kg) exceeds all manganese ATCs. The maximum concentration of manganese in RECs #9 and #10 surface soil is 2,390 mg/kg, and the second greatest detected concentration is 1,590 mg/kg.

Given that arsenic concentrations are, with the exception of the maximum concentration in REC #11 subsurface soil, similar to the ATC background values, most arsenic concentrations probably represent background conditions. Manganese concentrations in RECs #9 and #10 surface soil may slightly exceed background. However, manganese concentrations across GSP are within the range of other background values reported in the scientific literature. For example, Schacklette and Boerngen (1984) reported that manganese concentrations in soil in the eastern United States range from 2–7,000 mg/kg.

The metals chromium, cobalt, iron, and manganese were retained as COC for migration to groundwater, based on the analysis in Section 5.4. As noted earlier, no hexavalent chromium data were available for either EU evaluated. Chromium was conservatively included as a migration-to-groundwater COC based on the criterion for hexavalent chromium. The Maryland ATC for total chromium is 28 mg/kg for eastern Maryland. The maximum concentration of chromium in RECs #9 and #10 surface soil (24 mg/kg) and the maximum concentrations in REC #11 surface (24.1 mg/kg) and subsurface soil (27 mg/kg) are less than this ATC. The 95% UCL calculated for RECs #9 and #10 subsurface soil (14.9 mg/kg) is also less than this ATC. Therefore, most of the total chromium concentrations in soils likely reflect background concentrations.

The eastern Maryland ATC for cobalt in soil is 11 mg/kg. The maximum concentrations of cobalt in surface and subsurface soil are less than the eastern Maryland ATC for both the RECs #9 and #10 and REC #11 EUs. Therefore, cobalt concentrations in soil likely reflect background levels.

The eastern Maryland ATC for iron in soil is 15,000 mg/kg. The maximum concentrations of iron in RECs #9 and #10 surface and subsurface soil are less than this ATC, the maximum concentration of iron in REC #11 surface soil is equal to the ATC, and the maximum concentration of iron in REC #11 subsurface soil (15,600 mg/kg) is similar to this ATC. Therefore, most iron concentrations in soils likely reflect background concentrations.

Manganese was retained as a COC for migration to groundwater for RECs #9 and #10 surface and subsurface soil as well as REC #11 surface and subsurface soil. As noted above, some manganese concentrations in RECs #9 and #10 surface soil may exceed background concentrations. However, the maximum concentration of manganese in RECs #9 and #10 subsurface soil is less than the eastern Maryland ATC. The maximum concentrations of manganese in REC #11 surface soil and subsurface soil are 1,050 mg/kg and 713 mg/kg, respectively. These maximum concentrations exceed the eastern Maryland ATC but are less than the central and western ATC values and are within the literature background range.

Contaminants without established direct-contact screening levels—Risk-based screening levels are currently not available for some constituents detected at GSP. Appropriate surrogates for some

of these chemicals, based on similar chemical structures, were selected if available. In the COPC screening for soil, 1,4-dichlorobenzene was used as a surrogate for 1,3-dichlorobenzene, acenaphthene was used as a surrogate for acenaphthylene, and pyrene was selected as a surrogate for benzo(g,h,i)perylene and phenanthrene. For groundwater-vapor intrusion, trans-1,2-dichloroethene was used as a surrogate for cis-1,2-dichloroethene. Applying the toxicity values of one compound to another increases uncertainty in the risk assessment, with regard to both COPC selection and the calculated risks. The direction of the uncertainty is unknown.

Appropriate screening levels or surrogates were not available for several organic chemicals detected in soils and groundwater. Tertiary-butyl alcohol lacked COPC selection criteria in surface soil, and 4-isopropyltoluene and sec-butylbenzene lacked COPC selection criteria in subsurface soil. In groundwater, tertiary-butyl alcohol lacked COPC selection criteria. 4-Isopropyltoluene and sec-butylbenzene had frequencies of detection less than 5% in all subsurface soil. Only one sample was available for tertiary-butyl alcohol in surface soil and groundwater. Given that risk-based screening levels are available for most of the primary contaminants (in terms of concentration and frequency of detection), the lack of risk-based screening levels for some contaminants should not affect risk management decisions for GSP.

Use of USEPA generic SSLs for transfers from soil to groundwater for COPC selection— Several chemicals were selected as COPC because their maximum concentrations exceed USEPA generic SSLs for soil to groundwater contaminant migration (DAF = 1.0). However, USEPA's *Soil Screening Guidance* (USEPA, 1996a) states that "the USEPA has selected a default DAF of 20 to account for contaminant dilution and attenuation during transport through the saturated zone to a compliance point (i.e., a receptor well). At most sites, this adjustment will more accurately reflect a contaminant's threat to groundwater resources than assuming a DAF of 1 (i.e., no dilution or attenuation)." The guidance further states that "a DAF of 20 is protective for sources up to 0.5 acres in size" and "can be protective of larger sources as well." Consequently, the use of SSLs based on a DAF of 1 is very conservative. A more refined evaluation of the potential for chemical migration from soils is provided in Section 5.4 for surface and subsurface soils. COC were selected based on that analysis.

5.5.2 Exposure Assessment Uncertainty

Uncertainty in the exposure assessment arose because of the methods used to calculate EPCs, the determination of land use conditions, the selection of receptors and scenarios, and the selection of exposure parameters. Each of these is discussed below:

***Land use*—**Current land use patterns for the GSP area are well established, thereby limiting uncertainty associated with land use assumptions. Land use is currently limited to industrial/commercial uses, and the area will most likely remain commercial/industrial in the future, as MSA is an operating airport. To be conservative, receptors were considered for all possible future land uses, and risks to potential and future construction workers, industrial workers, visitors/trespassers, recreational users, and on-site residents were evaluated.

***Exposure-point concentrations*—**Uncertainty is associated with the use of the 95% UCL on the mean-concentration as the EPC. As a result of using the 95% UCL, estimations of potential risk for the RME scenario are most likely overstated because it represents the upper limit that potential receptors would be exposed to over the entire exposure period. In some cases (because data sets contained less than 10 samples, because less than three positive detections occurred, or because the UCL was greater than the maximum concentration), the maximum concentration was used as the EPC. For example, the maximum concentration was used as the EPC for groundwater for both EUs because fewer than 10 samples were available in each data set. Using the maximum concentration tends to overestimate potential risks because receptors are assumed to be continuously exposed to the maximum concentration for the entire exposure period. One-half of the detection limit was used for non-detected results for the location-by-location risk estimates in Appendix J. Using one-half the detection limit for non-detects can result in elevated risk estimates if detection limits are elevated.

EPCs for construction workers hypothetically exposed to VOCs migrating from shallow groundwater to air were estimated using a VDEQ model for exposure of construction workers to vapors accumulating in an excavation trench. Site-specific parameters such as groundwater concentrations were used in the model. However, the model's default values had to be used for most of the other input parameters. Using the model's default values tends to increase uncertainty in the calculated risks. The direction of the uncertainty is not known, although the model default values are generally conservative and tend to overestimate air concentrations.

***Exposure routes and receptor identification*—**Determination of various receptor groups and exposure routes of potential concern is based on observed current and anticipated future land use at the site. Therefore, uncertainty associated with selecting exposure routes and potential receptors is minimal because they are considered well defined.

***Exposure parameters*—**Each exposure factor selected for use in the risk assessment had some associated uncertainty. Exposure factors are generally based on surveys of physiological and lifestyle profiles across the United States. The attributes and activities studied in these surveys are generally broadly distributed. In most cases, to avoid underestimating exposure, USEPA guidelines on the RME receptor were used. These generally specify using the 95th-percentile value for most parameters. Therefore, the values selected for the RME receptor represent an upper bound of the observed or expected habits of most of the population. MDE exposure assumptions were used when available and applicable.

Uncertainty can generally be assessed quantitatively for many of the assumptions made in determining factors with which to calculate exposures and intakes. Many of these parameters were determined from statistical analyses of human population characteristics. Often, the database used to derive a particular exposure parameter (e.g., body weight) is relatively large. Consequently, the values chosen for such variables in the RME scenario have low uncertainty.

Many of the exposure parameters used to calculate exposures and risks in this report were selected from a distribution of possible values, including MDE guidance (State of Maryland, 2008) and USEPA guidance (USEPA, 1989, 1991, 1993, 1997a, 2004, 2011a). For the RME scenario, the value representing the 95th percentile was generally selected for each parameter to ensure that the assessment bounds most actual risks posed by a postulated exposure. This risk number is used in risk management decisions, but it does not indicate what an average and more-representative exposure might be, or what risk range might be expected for individuals in the exposed population.

5.5.3 Uncertainty in the Toxicological Evaluation

Uncertainties associated with the toxicity assessment (determination of RfDs and CSFs and use of available criteria) are discussed below.

Derivation of toxicity criteria—Uncertainty associated with the toxicity assessment is related to the hazard assessment and dose-response evaluations for the COPC. The hazard assessment characterizes the nature and strength of causal evidence or the likelihood that a chemical that induces adverse effects in animals will do likewise in humans. A hazard assessment of carcinogenicity was evaluated as a weight-of-evidence determination using USEPA methods. Positive animal-cancer test data suggest that humans contain tissue(s) that may manifest a carcinogenic response; however, animal data cannot necessarily be used to predict the target tissue in humans. In the hazard assessment of noncarcinogenic effects, however, positive animal data often suggest the nature of the effects (i.e., the target tissues and type of effects) to be anticipated in humans.

Uncertainty in hazard assessment arises from the nature and quality of the animal and human data. Uncertainty is reduced when:

- similar effects are observed across species, strain, sex, and exposure route
- the magnitude of the response is clearly dose related
- pharmacokinetic data indicate a similar fate in humans and animals
- postulated mechanisms of toxicity are similar for humans and animals
- the COC are structurally similar to other chemicals for which toxicity is more completely characterized

Uncertainty in the dose-response evaluation includes determining a CSF for the carcinogenic assessment and deriving an RfD for the noncarcinogenic assessment. Uncertainty is introduced from interspecies (animal to human) extrapolation, which, in the absence of quantitative pharmacokinetic or mechanistic data, is usually based on consideration of interspecies differences in basal metabolic rate. Uncertainty also results from intraspecies variation. Most toxicity experiments are performed on animals similar in age and genotype to minimize intragroup biological variation.

In contrast, the human population of concern may reflect a great deal of heterogeneity, including unusual sensitivity or tolerance to the COPC. Even toxicity data from human occupational exposures reflect a bias, because only those individuals sufficiently healthy to regularly attend work (the "healthy worker effect") and those not unusually sensitive to the chemical are likely to

be occupationally exposed. Finally, uncertainty arises from the quality of the key study from which the quantitative estimate is derived and which produced the database used. For cancer effects, the uncertainty associated with dose-response factors was mitigated by assuming the 95% upper bound for the slope factor.

Another source of uncertainty in carcinogenic assessment is the method by which data from high doses in animal studies are extrapolated to the dose range expected for environmentally exposed humans. The linearized multi-stage model, which is used in nearly all quantitative estimations of human risk based on animal data, is based on a nonthreshold assumption of carcinogenesis. Evidence suggests, however, that epigenetic carcinogens, as well as many genotoxic carcinogens, have a threshold below which they are noncarcinogenic. Therefore, using the linearized multi-stage model is conservative for chemicals that exhibit a threshold for carcinogenicity.

For noncarcinogenic effects, additional uncertainty factors may have been applied to derive the RfD to mitigate the poor quality of the key study or gaps in the resultant database. Additional uncertainty for noncarcinogenic effects arises from using an effect level in estimating an RfD, because this estimate is predicated on the assumption of a threshold less than that at which adverse effects are not expected. Therefore, an uncertainty factor is usually applied to estimate a no effect level.

Additional uncertainty arises in estimating an RfD for chronic exposure from subchronic data. Unless empirical data indicated that effects do not worsen with increasing exposure duration, an additional uncertainty factor was applied to the no effect level in the subchronic study. Uncertainty in deriving RfDs was mitigated by using uncertainty and modifying factors that normally range from 3–10. The resulting combination of uncertainty and modifying factors may have reached 1,000 or more. Deriving dermal RfDs and CSFs from oral-exposure values may also have introduced uncertainty. This is particularly the case when no gastrointestinal absorption rates are available in the literature, or when only qualitative statements regarding absorption are available.

Use of chronic toxicity values for construction workers—Under Superfund program guidelines, exposures posed to construction workers for one year or less are classified as subchronic exposures. Risks for noncarcinogenic effects associated with subchronic exposures should incorporate toxicity values for subchronic and not chronic effects. Subchronic toxicity values

used in this HHRA were obtained from USEPA's PPRTV Internet URL (http://hhpprtv.ornl.gov/quickview/pprtv.php). ATSDR Minimal Risk Levels (MRLs) were used as subchronic toxicity-values when PPRTV values were not available. Unfortunately, subchronic toxicity values are not as widely available as chronic values. Therefore, chronic toxicity values were used when subchronic toxicity values were not available. As discussed below, the lack of subchronic toxicity values is a significant source of uncertainty for receptors anticipated to have limited exposure durations (e.g., the construction worker).

Construction worker HIs for surface soil in RECs #9 and #10 and for both surface and subsurface soil in REC #11 exceed 1 primarily due to manganese via the inhalation exposure route. The toxicity criteria used to calculate the manganese HI for the construction worker include an RfC of 5×10^{-5} mg/m^3 (from USEPA's *IRIS*). This RfC is for *chronic* exposures (i.e., long-term exposures extending over a period of seven or more years); for the construction worker scenario, subchronic toxicity values are more appropriate because the exposure duration assumed for the construction worker is one year (i.e., the assumed length of a typical construction project). However, a subchronic RfC is not currently available from *IRIS* or other USEPA literature sources cited in the hierarchy specified in USEPA guidance (2003b). The fact that the EPCs calculated for manganese in REC #11 surface soil (370 mg/kg) and REC #11 subsurface soil (713 mg/kg) are less than the current residential soil RSL (1,800 mg/kg) yet still result in an HQ exceeding 1 for manganese is evidence that the construction worker HQ for manganese is likely overestimated. Although the EPC for manganese in RECs #9 and #10 surface soil (2,200 mg/kg) exceeds the residential soil RSL, it is within one order of magnitude of the residential soil RSL and less than the industrial soil RSL (23,000 mg/kg).

The chronic RfC for manganese used in this baseline risk assessment was developed in 1993 by USEPA. However, Bailey, et al., (2009) used more recent toxicological studies than those used by the USEPA in 1993 to develop two alternative chronic RfCs for manganese: 2×10^{-3} mg/m^3 and 7×10^{-3} mg/m^3. If the more conservative of Bailey, et al.'s alternative RfCs (i.e., 2×10^{-3} mg/m^3) is used to calculate potential risk, soil HIs for the construction worker would not exceed 1 on a target-organ-specific basis. Therefore, the toxicity criteria used for manganese are a significant source of uncertainty.

Uncertainty in the toxicity criteria for Aroclor-1260—Aroclor-1260 was selected as a global direct-contact COPC in both surface and subsurface soil. No noncarcinogenic toxicity criteria are available for Aroclor-1260, and this lack adds uncertainty. However, a noncarcinogenic RfD is available for Aroclor-1254, a related compound that was not detected in study area media. The noncarcinogenic residential soil RSL for Aroclor-1254 is 1,100 µg/kg. The EPCs calculated for Aroclor-1260 detected in RECs #9 and #10 surface and subsurface soil (i.e., 63 µg/kg and 64 µg/kg, respectively) are less than the noncarcinogenic RSL for Aroclor-1254. The EPCs calculated for Aroclor-1260 in REC #11 surface and subsurface soil (i.e., 1,600 µg/kg and 1,200 µg/kg, respectively) slightly exceed the noncarcinogenic RSL for Aroclor-1254. However, Aroclor-1260 has already been identified as a risk driver in REC #11 surface and subsurface soil for residential receptors. Using the Aroclor-1254 RfD for Aroclor-1260 would not lead to HIs exceeding 1 on a target organ basis for construction workers, industrial workers, trespassers, or recreational users. Therefore, the lack of noncarcinogenic toxicity criteria for Aroclor-1260 does not change overall risk assessment conclusions.

Uncertainty in the toxicity criteria for chromium—Toxicity criteria are available for different forms of chromium, which is considered more toxic in the hexavalent state. The following table compares the maximum total-chromium concentrations reported for the GSP EUs to available USEPA RSLs:

Environmental medium (maximum concentration)	USEPA RSL residential scenario (assuming hexavalent chromium)	USEPA RSL residential scenario (assuming trivalent chromium)
Surface soil: RECs #9 & #10 = 24 mg/kg REC #11 = 24.1 mg/kg	0.29 mg/kg	120,000 mg/kg
Subsurface soil: RECs #9 &10 = 39 mg/kg REC #11 = 27 mg/kg		
Groundwater: RECs #9 & #10 = 8.2 µg/L REC #11 = 7.5 µg/L	0.031 µg/L	16,000 µg/L

No hexavalent chromium data are available for GSP for either soil or groundwater. As indicated in Section 5.3, an assumption that 1% of total chromium in soil is present in the hexavalent state

was made for the Dump Road Area, and that same assumption was made for GSP. As in the HHRA for the Dump Road Area, chromium in groundwater was conservatively assumed present in the hexavalent state. Risks calculated for chromium in soil, assuming 1% of total chromium is in the hexavalent form, and risks for groundwater calculated assuming all chromium was present in the hexavalent form, are likely overestimated.

Hexavalent chromium is not a primary risk driver in soil for any receptor. Therefore, the conclusions of the HHRA are not affected by assuming 1% of total chromium in soil is present in the hexavalent form. Hexavalent chromium in groundwater was found to be a primary carcinogenic risk driver for residents. As stated earlier, all total chromium data are assumed to be in the hexavalent form in groundwater. This was done for the Dump Road Area because available hexavalent chromium data in groundwater at the Dump Road Area were unsuitable for developing a quantitative ratio of total chromium to hexavalent chromium (Tetra Tech, 2010).

Regardless of the assumptions made to predict the percentages of hexavalent chromium in groundwater, the medium-specific ILCRs for lifelong residents in both EUs would still exceed USEPA's target cancer-risk range and MDE's target cancer-risk level even if chromium were not selected as a COPC. Therefore, risk assessment conclusions are not affected by the assumptions made regarding chromium in groundwater. Even so, risks for hexavalent chromium in groundwater are likely overestimated by this assumption.

Refined risk evaluation of GRO/DRO concentrations—The risk evaluation in Section 5.4 includes a qualitative discussion of GRO and DRO concentrations to MDE's *Generic Numeric Cleanup Standards for Soil*. DRO and GRO were not evaluated quantitatively in Section 5.4 because USEPA has not published toxicity criteria (e.g., RfDs or CSFs) for these parameters. However, as noted in the 2008 MDE *Guidance for Cleanup Standards for Soil and Groundwater*, some state regulators have established protocols for the quantitative risk assessment of these parameters.

An example of such protocols is found in Massachusetts' final policy #WSC-02-411 (*Characterizing Risks Posed by Petroleum Contaminated Sites: Implementation of the MADEP VPH/EPH Approach*) (State of Massachusetts, 2002). This methodology is cited in the referenced MDE guidelines as the basis of the published generic standards for soil. Although

quantitative risk estimates based on this methodology (and the associated toxicity criteria) are more uncertain than those based on USEPA recommended toxicity criteria, for purposes of completeness, the following tables provide noncancer-risk estimates (HIs) for GRO/DRO, based on a simple comparison of EPCs to risk-based concentrations developed using the methodology endorsed by MDE to develop the generic standards (see Appendix J).

The evaluation indicates that although some isolated detected concentrations of GRO/DRO clearly exceed the MDE generic standards (see Section 5.4), risk estimates based on the EPCs for all receptors (except the resident exposed to groundwater in RECs #9 and #10) do not indicate that these parameters are major contributors to noncancer risk for hypothetical exposure to GSP soil or groundwater. The HI for a child resident exposed to DRO at RECs #9 and #10 exceeds 1. The maximum concentration of DRO used as the EPC for groundwater in RECs #9 and #10 is from MW-06; the second greatest concentration of DRO (1,400 µg/L) was detected in MW-05. No other groundwater samples from RECs #9 and #10 have DRO concentrations exceeding the MDE residential cleanup standard of 470 µg/L.

Furthermore, this evaluation is limited in that it does not consider the potential carcinogenic effects of the GRO/DRO constituents (e.g., benzo(a)pyrene and related chemicals). However, the chemical-specific risk assessment in Section 5.4 does account for a number of these constituents.

RECs #9 and #10—Refined Evaluation of GRO/DRO (Hazard Indices)

RECs #9 and #10	Surface soil DRO	Subsurface soil DRO	Groundwater DRO	Groundwater GRO
EPC (mg/kg or µg/L)	350	220	1,600	300
Ratio of EPC to residential RBC (2,300 mg/kg or 470 µg/L)	*0.2*	<0.1	**3**	*0.6*
Ratio of EPC to trespasser RBC (16,000 mg/kg)	<0.1	<0.1	NA	NA
Ratio of EPC to industrial RBC (61,000 mg/kg)	<0.1	<0.1	NA	NA
Ratio of EPC to recreational RBC (12,000 mg/kg)	<0.1	<0.1	NA	NA

REC #11—Refined Evaluation of GRO/DRO (Hazard Indices)

REC #11	Surface soil DRO	Subsurface soil DRO	Groundwater DRO	Groundwater GRO
EPC (mg/kg or µg/L)	660	1,400	360	Not detected
Ratio of EPC to residential RBC (2,300 mg/kg or 470 µg/L)	*0.3*	*0.6*	*0.8*	NA
Ratio of EPC to trespasser RBC (16,000 mg/kg)	<0.1	<0.1	NA	NA
Ratio of EPC to industrial RBC (61,000 mg/kg)	<0.1	<0.1	NA	NA
Ratio of EPC to recreational RBC (12,000 mg/kg)	<0.1	0.1	NA	NA

5.5.4 Uncertainty in the Risk Characterization

Uncertainty in risk characterization resulted from assumptions made regarding additivity of effects from exposure to multiple COPC via various exposure routes. High uncertainty exists when summing noncarcinogenic risks for several substances across different exposure pathways. This assumes that each substance has a similar effect and/or mode of action. Even when compounds affect the same target organs, they may have different mechanisms of action or differ in their fate in the body, so additivity may not be an appropriate assumption in all cases. However, the assumption of additivity was considered because in most cases it represents a conservative estimate of risk. Risks to any individual may also have been overestimated by summing multiple assumed exposure-pathway risks for any single receptor. Although every effort was made to develop reasonable scenarios, not all individual receptors may be exposed via all pathways considered.

Finally, the risk characterization does not consider antagonistic or synergistic effects. Little or no information is available to determine the potential for antagonism or synergism among the COPC. The likelihood of over- or under-predicting risks could not be defined because chemical-specific interactions could not be predicted; however, the methodology used is based on current USEPA guidance.

5.6 REMEDIAL GOAL OPTIONS

Cleanup goals were developed for those environmental media with ILCRs greater than 1×10^{-5} and a total HI greater than 1. Cleanup goals were derived for those COC that contribute significantly to the cancer risk and/or HI for each exposure pathway in a given land-use scenario for a receptor group. Chemicals were not considered significant contributors to risk, and were therefore not included as COC, if their individual carcinogenic risk contribution was less than or equal to 1×10^{-6} and their noncarcinogenic HQ was less than or equal to 0.1. Cleanup goals were calculated using the following equation:

$$\text{Cleanup Goal [chemical i]} = \text{EPC[chemical i]} \times \text{Target Risk/Calculated Risk[chemical i]}$$

where:

Cleanup goal [chemical i]	=	chemical-specific cleanup goal
EPC [chemical i]	=	exposure-point concentration used in risk assessment calculations
Target risk	=	target risk for carcinogens or the target hazard quotients for noncarcinogens
Calculated risk [chemical i]	=	total risk calculated for a specific chemical in the risk assessment

Cleanup goals calculated for soil and groundwater for each EU are in Tables 5-36 through 5-39. These tables include potential USEPA RSL criteria and MCLs, when available.

5.7 SUMMARY

The baseline HHRA for GSP was performed to characterize potential risks to likely human receptors that could potentially be exposed to soils and groundwater under current and future land use. The potential receptors evaluated were construction workers, industrial workers, trespassers, recreational users, and hypothetical future residents. Although future land use is unlikely to change from industrial/commercial land uses, potential future receptors were evaluated in the baseline HHRA, primarily for decision-making purposes.

Chemicals of potential concern were selected for direct-contact routes of exposure to environmental media, for the vapor-intrusion pathway, and for the potential migration of chemicals from soils to

groundwater pathway. The "global" COPC evaluated for surface soil for direct-contact exposure were benzo(a)pyrene equivalents constituents, n-nitroso-di-n-propylamine, PCBs, several metals, and DRO. The "global" COPC for subsurface soil for direct-contact exposure were naphthalene (as both a VOC and SVOC), benzo(a)pyrene-equivalent constituents, PCBs, several metals, and DRO. The "global" groundwater COPC for direct-contact exposure were VOCs (particularly trichloroethene), SVOCs, several metals, DRO, and GRO. The COPC for the vapor-intrusion pathway were trichloroethene, and, to a lesser extent, benzene, carbon tetrachloride, chloroform, and vinyl chloride. Many of these same organic and inorganic chemicals were also selected as COPC to evaluate chemical migration from soils to groundwater.

Quantitative estimates of noncarcinogenic and carcinogenic risks (HIs and ILCRs, respectively) were developed for potential human receptors directly contacting site environmental media. Media with risk estimates exceeding Maryland's one in 100,000 cumulative cancer-risk benchmark (i.e., 1×10^{-5}), or an HI of 1, are identified in the following tables for each EU:

Summary of Direct-Contact Risk Estimates—RECs #9 and #10
(Ingestion, Dermal Contact, and Inhalation of COPC)

Environmental medium	Receptors	Chemicals of concern[1]
Surface soil	Construction worker(2)(4) Typical industrial worker(3) Child trespasser(3) Lifelong recreational user(3) Child resident(2) Lifelong resident(3)	BaPEq, As(5), Mn
Subsurface soil	Child trespasser(3) Lifelong recreational user(3) Lifelong resident(3)	BaPEq, As(5), Aroclor-1260
Groundwater	Child resident(2) Adolescent resident(2) Adult resident(2) Lifelong resident(3)	Benzene(6), Carbon tetrachloride(6), TCE, As(6), Co, Cr VI(7), Mn

[1]The following abbreviations are used: As: arsenic, BaPEq: benzo(a)pyrene equivalents, Cr VI: hexavalent chromium, Co: cobalt, Mn: manganese, TCE: trichloroethene.

[2]Receptor risks exceed non-cancer-risk benchmark of target organ-specific HI greater than 1.

[3]Receptor risks exceed 1E-05 cancer-risk benchmark. Risk estimates presented for the lifelong recreational user and lifelong resident (estimates not presented for the various age groups that define this receptor).

[4]Manganese is the only COC for this receptor; however, considerable uncertainty is associated with the HI estimated for manganese (see Section 5.5, Uncertainty Analysis).

[5]Arsenic concentrations likely represent background.

[6]The maximum concentration of this chemical in RECs #9 and #10 groundwater is less than the MCL.

[7] Cr VI was evaluated by assuming 100% of total chromium is present in the hexavalent state; considerable uncertainty is associated with this assumption (see Section 5.5, Uncertainty Analysis). The maximum concentration of total chromium in RECs #9 and #10 groundwater is less than the total chromium MCL.

Summary of Direct-Contact Risk Estimates—REC #11 (Ingestion, Dermal Contact, and Inhalation of COPC)

Environmental medium	Receptors	Chemicals of concern[1]
Surface soil	Construction worker(2,4) Child trespasser(3) Lifelong recreational user(3) Lifelong resident(3)	BaPEq, n-nitroso-di-n-propylamine(9), Aroclor-1260, As(3), Mn(6)
Subsurface soil	Construction worker(2,4) Child trespasser(3) Lifelong recreational user(3) Lifelong resident(3)	BaPEq, As, Aroclor-1260, Mn(6)
Groundwater	Child resident(2) Adolescent resident(2) Adult resident(2) Lifelong resident(3)	TCE, VC(7), As, Co(10), Cr VI(8), Fe, Tl(7,10)

[1]The following abbreviations are used: As: arsenic, BaPEq: benzo(a)pyrene equivalents, Co: cobalt, Cr VI: hexavalent chromium, Fe: iron, Mn: manganese, TCE: trichloroethene, Tl: thallium, VC: vinyl chloride.

[2]Receptor risks exceed noncancer-risk benchmark of target organ-specific HI greater than 1.

[3]Receptor risks exceed 1E-05 cancer-risk benchmark. Risk estimates presented for the lifelong recreational user and lifelong resident (estimates not presented for the various age-groups that define this receptor).

[4]Manganese is the only COC for this receptor; however, considerable uncertainty is associated with the HI estimated for manganese (see Section 5.5, Uncertainty Analysis).

[5]Arsenic concentrations likely represent background.

[6]Manganese is a COC for the construction worker only; see footnote #4.

[7]The maximum concentration of this chemical in REC #11 groundwater is less than the maximum contaminant level (MCL).

[8]Cr VI was evaluated by assuming 100% of total chromium is present in the hexavalent state; considerable uncertainty is associated with this assumption (see Section 5.5, Uncertainty Analysis). The maximum concentration of total chromium in REC #11 groundwater is less than the total chromium MCL.

[9]This compound was detected in only one of 32 REC #11 surface soil samples.

[10]These metals had notably higher concentrations in temporary well GSP-SB-084 than in other wells for cobalt and thallium. This is an important consideration because the maximum concentration was used as the exposure point concentration (EPC) for groundwater.

No quantitative evaluation of vapor intrusion was conducted. However, a qualitative evaluation was conducted for the vapor-intrusion COPC for a hypothetical future resident or worker, assuming exposure to VOCs in the indoor air of a building. Results for each EU are summarized below:

Summary of Vapor-Intrusion Pathway COC[(1)]

(Volatile Organic Chemical Migration from Shallow Groundwater to the Indoor Air of a Building)

Exposure unit	Chemicals of concern
RECs #9 and #10	Trichloroethene
REC # 11	Trichloroethene

[1]The maximum detected concentration in groundwater from all wells in each exposure unit was used as the exposure-point concentration for the qualitative analysis.

Trichloroethene was selected as a vapor-intrusion COC for both RECs #9 and #10 and REC #11, based on a qualitative analysis of the available data (e.g., frequencies of detection, magnitude of exceedances). Trichloroethene was also selected as a COC for direct contact with groundwater in both EUs evaluated.

The following chemicals were selected as COC based on their potential to migrate from soils to groundwater:

Chemicals of Concern for Migration from Soils to Groundwater

Analytical fraction	Chemicals selected as COC
Volatile organic chemicals	Trichloroethene
PCBs[(1)]	Aroclor-1260, total Aroclor
Metals[(1)]	Cr VI, Co, Fe, Mn

Cr VI : hexavalent chromium, Co: cobalt, Fe: iron, Mn: manganese.

[1]Although the analysis suggests these chemicals are COC, these chemicals are not recommended for further evaluation based on the rationale in Section 5.4.3.7.

The COC list is similar to that identified for the direct-contact exposure pathways. Chemical concentrations of COC in soil exceed groundwater protection criteria based on a DAF of 20, and their concentrations in groundwater exceed tap water RSLs or MDE cleanup standards for groundwater and available SDWA MCLs. These chemicals are not recommended for further

evaluation if their concentrations are similar to background concentrations (for metals) or because their direct-contact risk-based remedial goals are generally more conservative (for PCBs).

It should be noted that the human health risk estimates presented in Section 5 were calculated in a conservative manner to assist risk managers tasked with making risk management decisions for RECs #9, #10, and #11. These sites are currently within active airport area which is not used for residential or recreational purposes, and the potential for trespass is very limited. The groundwater resource is not used as a domestic water supply source. Thus, to a large extent, the risk estimates presented herein are for *hypothetical* receptor exposure should the land use scenario change.

Petroleum Hydrocarbons						
- -	Diesel Range Organics	NA	NA	230	NA	NA
- -	Gasoline Range Organics	NA	NA	230	NA	NA

Notes:
1 - United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites, June 2011. Values correspond to a cancer risk level of 1E-06 or a hazard quotient (HQ) of 1.0.
2 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
3 - USEPA Soil Screening Levels. USEPA Internet Site at http://rais.ornl.gov/epa/ssl1.shtml.
4 - One tenth the noncarcinogenic level is less than the carcinogenic level; therefore, the non-carcinogenic level is presented.
5 - The value is for 1,4-dichlorobenzene.
6 - The value is for m-xylene.
7 - The value is for xylenes.
8 - The value is for acenaphthene.
9 - The value is for pyrene.
10 - The value is for polychlorinated biphenyls (PCBs) [high risk].
11 - The value is for PCB (total).
12 - The value is for hexavalent chromium.
13 - Maximum Contaminant Level (MCL)-based soil screening level (SSL).
14 - The value is for mercuric chloride (and other mercury salts).
15 - The value is for mercury (inorganic/mercuric dichloride).
16 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.

C = Carcinogenic
CAS = Chemical Abstract Service
MDE = Maryland Department of the Environment
mg/kg = milligram per kilogram
N = Non-carcinogenic
NA = Not available/not applicable
PCB = polychlorinated biphenyl
sat = Soil saturation concentration
USEPA = United States Environmental Protection Agency

Petroleum Hydrocarbons					
- -	Diesel Range Organics	NA	47	NA	NA
- -	Gasoline Range Organics	NA	47	NA	NA

Notes:
1 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, June 2011. Values correspond to a cancer risk level of 1E-06 or a hazard quotient (HQ) = 1.0.
2 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
3 - 2011 Edition of the Drinking Water Standards and Health Advisories (USEPA, January 2011).
4 - Calculated using methodology presented in Appendix D of USEPA's Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils, November 2002. EPA530-F-02-052. Values correspond to a target cancer risk level of 1E-6 or HQ = 1 and an attenuation factor of 0.001.
5 - Value is for trans-1,2-dichloroethene.
6 - Value is for xylenes.
7 - Value is for m-xylene.
8 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.
9 - The value is for hexavalent chromium.
10 - The value is for total chromium.
11 - The value is for mercuric chloride (and other mercury salts).

C = Carcinogenic
CAS = Chemical Abstract Service
MCL = Maximum Contaminant Level
MDE = Maryland Department of the Environment
N = Non-carcinogenic

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - State of Maryland Department of the Environment Cleanup Standards for Soil and Groundwater, June 2008. Appendix 2 - Attachment 2.
5 - United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites, June 2011. Adjusted values correspond to a cancer risk level of 1E-06 or a hazard quotient (HQ) of 0.1.
6 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
7 - USEPA Soil Screening Levels (SSLs). USEPA Internet Site at http://rais.ornl.gov/epa/ssl1.shtml.
8 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
9 - One tenth the non-carcinogenic level is less than the carcinogenic level; therefore, the non-carcinogenic level is presented.
10 - The value is for 1,4-dichlorobenzene.
11 - The value is for xylenes.
12 - The value is for acenaphthene.
13 - The value is for pyrene.
14 - The value is for hexavalent chromium.
15 - The value is for mercuric chloride (and other mercury salts).
16 - The value is for mercury (inorganic/mercuric dichloride).
17 - See text for BaP equivalent calculation methodology.
18 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Definitions:
BaP = benzo(a)pyrene
C = carcinogen
COPC = chemical of potential concern
J = estimated value
K = biased high
L = biased low
mg/kg = milligram per kilogram
N = non-carcinogen
NA = not applicable/not available
sat = soil saturation concentration
ug/kg = microgram per kilogram

Rationale Codes:
For selection as a COPC:
ASL = above screening level

For elimination as a COPC:
BSL = below screening level
NTX = no toxicity criteria

TABLE 5-8

OCCURRENCE, DISTRIBUTION, AND SELECTION OF GLOBAL CHEMICALS OF POTENTIAL CONCERN - ALL SURFACE SOIL - MIGRATION TO GROUNDWATER
GREATER STRAWBERRY POINT
LOCKHEED MARTIN, MARTIN STATE AIRPORT
MIDDLE RIVER, MARYLAND

Exposure Point	CAS Number	Chemical	Minimum Concentration[1]	Maximum Concentration[1]	Units	Sample of Maximum Concentration	Frequency of Detection	Range of Nondetects[2]	Concentration Used for Screening[3]	Range of Background Concentrations[4]	USEPA SSL - Groundwater Protection[5]	MDE Cleanup Standard - Groundwater Protection[6]	COPC Flag	Rationale for Contaminant Deletion or Selection[7]

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - State of Maryland Department of the Environment Cleanup Standards for Soil and Groundwater, June 2008. Appendix 2 - Attachment 2.
5 - United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites, soil screening levels (SSLs) for groundwater protection, June 2011.
6 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
7 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
8 - The value is for 1,4-dichlorobenzene.
9 - The value is for xylenes.
10 - The value is for acenaphthene.
11 - The value is for pyrene.
12 - The value is for hexavalent chromium.
13 - Maximum Contaminant Level (MCL)-based soil screening level (SSL).
14 - See text for BaP equivalent calculation methodology.
15 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.

Definitions:
BaP = benzo(a)pyrene
C = carcinogen
COPC = chemical of potential concern
J = estimated value
K = biased high
L = biased low
mg/kg = milligram per kilogram
N = non-carcinogen
NA = not applicable/not available
ug/kg = microgram per kilogram

Rationale Codes:
For selection as a COPC:
ASL = Above screening level

For elimination as a COPC:
BSL = Below screening level
NTX = No toxicity criteria

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as COPC.

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - To determine whether chemical concentrations were within background levels, a statistical analysis was conducted using the site and background datasets.
5 - United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites, June 2011. Adjusted values correspond to a cancer risk level of 1E-06 or a hazard quotient (HQ) of 0.1.
6 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
7 - USEPA Soil Screening Levels (SSLs). EPA Internet Site at http://rais.ornl.gov/epa/ssl1.shtml.
8 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
9 - The value is for m-xylene.
10 - The value is for xylenes.
11 - One tenth the non-carcinogenic level is less than the carcinogenic level; therefore, the non-carcinogenic level is presented.
12 - The value is for acenaphthene.
13 - The value is for pyrene.
14 - The value is for polychlorinated biphenyls [PCBs] (high risk).
15 - The value is for PCB (total).
16 - The value is for hexavalent chromium.
17 - The value is for mercuric chloride (and other mercury salts).
18 - The value is for mercury (inorganic/mercuric dichloride).
19 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chmical was retained as a COPC.

Definitions:
BaP = benzo(a)pyrene
C = Carcinogen
COPC = Chemical of potential concern
J = Estimated value
L = Biased low
mg/kg = milligram per kilogram
N = Non-carcinogen
NA = Not applicable/not available
PCB = polychlorinated biphenyl
sat = soil saturation concentration
ug/kg = microgram per kilogram

Rationale Codes:
For selection as a COPC:
ASL = Above screening level

For elimination as a COPC:

BSL = Below screening level
NTX = No toxicity criteria

Table 5-10

Occurrence, Distribution, and Selection of Chemicals of Global Potential Concern – All Subsurface soil (2-15 feet) - Migration to Groundwater
Greater Strawberry Point
Lockheed Martin, Martin State Airport
Middle River, Maryland

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - To determine whether chemical concentrations were within background levels, a statistical analysis was conducted using the site and background datasets.
5 - United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites, June 2011. [Cancer benchmark value = 1E-06, Hazard index (HI) = 0.1].
6 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
7 - USEPA Soil Screening Levels (SSLs). USEPA Internet Site at http://rais.ornl.gov/epa/ssl1.shtml.
8 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
9 - The value is for xylenes.
10 - The value is for acenaphthene.
11 - The value is for pyrene.
12 - The value is for polychlorinated biphenyls (high risk).
13 - The value is for hexavalent chromium.
14 - Maximum Contaminant Level (MCL)-based soil screening level (SSL).
15 - See text for BaP equivalent calculation methodology.
16 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was reatined as a COPC.

Definitions:
BaP = benzo(a)pyrene
C = carcinogen
COPC = chemical of potential concern
J = estimated value
L = biased low
mg/kg = milligram per kilogram
N = non-carcinogen
NA = not applicable/not available
sat = soil saturation concentration
ug/kg = microgram per kilogram

Rationale Codes:
For selection as a COPC:
ASL = above screening level

For elimination as a COPC:
BSL = below screening level
NTX = no toxicity criteria

Associated Samples:

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - State of Maryland Department of the Environment Cleanup Standards for Soil and Groundwater, June 2008. Appendix 2 - Attachment 2.
5 - United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites, June 2011. Adjusted values correspond to a cancer risk level of 1E-06 or a hazard quotient (HQ) of 0.1.
6 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
7 - USEPA Soil Screening Levels (SSLs). USEPA Internet Site at http://rais.ornl.gov/epa/ssl1.shtml.
8 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
9 - One tenth the non-carcinogenic level is less than the carcinogenic level; therefore, the non-carcinogenic level is presented.
10 - The value is for 1,4-dichlorobenzene.
11 - The value is for xylenes.
12 - The value is for acenaphthene.
13 - The value is for pyrene.
14 - The value is for hexavalent chromium.
15 - The value is for mercuric chloride (and other mercury salts).
16 - The value is for mercury (inorganic/mercuric dichloride).
17 - See text for BaP equivalent calculation methodology.
18 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.
Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Definitions:
BaP = benzo(a)pyrene
C = carcinogen
COPC = chemical of potential concern
J = estimated value
K = biased high
L = biased low
mg/kg = milligram per kilogram
N = non-carcinogen
NA = not applicable/not available
sat = soil saturation concentration
ug/kg = microgram per kilogram

Rationale Codes:
For selection as a COPC:
ASL = above screening level

For elimination as a COPC:
BSL = below screening level
NTX = no toxicity criteria

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - No background data is available for groundwater.
5 - United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) for Chemical Contaminants at Superfund Sites, June 2011.
Adjusted values correspond to a cancer risk level of 1E-06 or a hazard quotient (HQ) of 0.1.
6 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
7 - 2011 Edition of the Drinking Water Standards and Health Advisories (USEPA, January 2011).
8 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
9 - Value is for xylenes.
10 - The value is for hexavalent chromium.
11 - The value is for total chromium.
12 - The value is for mercuric chloride (and other mercury salts).
13 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.

Definitions:
C = carcinogen
COPC = chemical of potential concern
J = estimated value
N = non-carcinogen
NA = not applicable/not available
µg/L = microgram per liter

Rationale Codes:
For selection as a COPC:
ASL = above screening level

For elimination as a COPC:
BSL = below screening level
NTX = no toxicity criteria

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Footnotes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - No background data is available for groundwater.
5 - Calculated using methodology presented in Appendix D of USEPA's Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils, November 2002. EPA530-F-02-052. Adjusted values correspond to a target cancer risk level of 1E-06 or a hazard quotient (HQ) of 0.1 and an attenuation factor of 0.001.
6 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
7 - Value is for trans-1,2-dichloroethene.
8 - Value is for m-xylene.
9 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Definitions:
ARAR/TBC = Applicable or relevant and appropriate requirements to be considered
C = Carcinogen
COPC = Chemical of potential concern
J = Estimated value
N = Non-carcinogen
NA = Not applicable/not available
µg/L = microgram per liter

Rationale Codes:
For selection as a COPC:
ASL = Above screening level

For elimination as a COPC:
BSL = Below screening level
NTX = No toxicity criteria

Notes:
COPC - Chemical of potential concern.
Qual - Qualitative.
Quant - Quantitative.

Table 5-16

Receptors and Exposure Routes for Quantitative Evaluation
Greater Strawberry Point
Lockheed Martin, Martin State Airport
Middle River, Maryland

Receptors	Exposure Routes
Construction Workers (current/future land use)	• Soil incidental ingestion (surface/subsurface) • Soil dermal contact (surface/subsurface) • Inhalation of air/dust/emissions • Groundwater incidental ingestion (during excavation) • Groundwater dermal contact (during excavation) • Groundwater inhalation of volatile organics (during excavation)
Commercial/Industrial Workers (current/future land use)	• Soil ingestion (surface/subsurface[1]) • Soil dermal contact (surface/subsurface[1]) • Inhalation of air/dust/emissions (surface/subsurface[1]) • Inhalation of vapors intruding into a building from the groundwater[2]
Visitors/Trespassers (child and adolescent) (current/future land use)	• Soil ingestion (surface/subsurface[1]) • Soil dermal contact (surface/subsurface[1]) • Inhalation of air/dust/emissions (surface/subsurface[1])
Recreational Users (child, adolescent, and adult) (future land use)	• Soil ingestion (surface/subsurface[1]) • Soil dermal contact (surface/subsurface[1]) • Inhalation of air/dust/emissions (surface/subsurface[1])
Hypothetical Residents (child, adolescent, and adults) (future land use)	• Soil ingestion (surface/subsurface[1]) • Soil dermal contact (surface/subsurface[1]) • Inhalation of air/dust/emissions (surface/subsurface[1]) • Groundwater ingestion • Groundwater dermal contact (showering/bathing) • Inhalation of volatiles in groundwater (showering/bathing) • Inhalation of vapors intruding into a building from the groundwater [2]

1 – These receptors are not expected to be exposed to subsurface soil, but exposure to subsurface is evaluated to aid in risk management decisions.
2 – The vapor intrusion exposure route is evaluated qualitatively.

Table 5-17

Exposure Point Concentrations
Greater Strawberry Point
Lockheed Martin, Martin State Airport
Middle River, Maryland

Notes:
1 - The maximum concentration is used as the EPC when there are less than 10 samples or 3 positive detections.
2 - 99% KM (Chebyshev) UCL.
3 - 95% KM (Chebyshev) UCL.
4 - 95% Approximate Gamma UCL.
5 - 95% Student's-t UCL.
6 - 99% Chebyshev (Mean, Sd) UCL.
7 - 95% H-UCL.
8 - 95% KM (t) UCL.
9 - 97.5% KM (Chebyshev) UCL.
10 - 95% KM (Percentile Bootstrap) UCL.
11 - 95% KM (BCA) UCL.
12 - One percent of total chromium in soil was evaluated as hexavalent chromium; therefore, one percent of this EPC was used in the quantitative risk evaluation.

EPC - Exposure point concentration.
kg - kilogram
KM - Kaplan-Meier method
L - liter
µg - microgram
mg - milligram
NA - Not applicable, not a COPC for this medium or exposure unit.
UCL - upper confidence limit

RAGS Part D tables for the exposure point concentrations and ProUCL printouts are included in Appendix H.

Table 5-18

Summary of Exposure Input Parameters - Reasonable Maximum Exposure (RME)
Greater Strawberry Point
Lockheed Martin, Martin State Airport
Middle River, Maryland

Notes:

ABS	Absorption factor
AF	Soil-to-skin adherence factor
AT_c	Averaging time for carcinogenic effects
AT_n	Averaging time for non-carcinogenic effects
B	Bunge Model partitioning coefficient
BW	Body weight
CF	Conversion factor
cm	centimeter
CR	Contact rate
$C_{soil/gw/air}$	Exposure concentration for soil/groundwater/air
ED	Exposure duration
EF	Exposure frequency
ET	Exposure time
EV	Event frequency
FI	Fraction ingested from contaminated source
IR	Ingestion rate
K_p	Permeability coefficient from water through skin
L	liter
m	meter
mg	milligram
PEF	Particulate emissions factor
Q/C	Inverse of mean concentration at the center of the source
SA	Skin surface area available for contact
τ	Lag time
t*	Time it takes to reach steady-state conditions
t_{event}	Duration of event
UCL	upper confidence limit
VF	Volatization factor

atm - atmosphere
cm - centimeter
g - grams
L - liter
m - meter
mg - milligram
sec - second

Table 5-20

Input Parameters for Calculation of the Volatilization from Soil to Outdoor Air Models
Greater Strawberry Point
Lockheed Martin, Martin State Airport
Middle River, Maryland

Parameter	Definition	Value	Reference
Q/C	Inverse of mean concentration at center of source (g/m^2-s per kg/m^3).	Receptor specific(1)	USEPA, 2011a, 2002
T	Exposure interval (seconds).	Receptor specific(2)	USEPA, 2002
pb	Dry soil bulk density (g/cm^3).	1.5	USEPA, 2002
ps	Soil particle density (g/cm^3).	2.65	USEPA, 2002
θw	Water-filled soil porosity (L_{pore}/L_{soil}).	0.15	USEPA, 2002
n	Total soil porosity (L_{pore}/L_{soil}).	0.434	USEPA, 2002
Di	Diffusivity in air (cm^2/sec).	Chemical specific(3)	USEPA, 2011b
H'	Dimensionless Henry's Law Constant.	Chemical specific(3)	USEPA, 2011b
S	Solubility limit (mg/L)	Chemical specific(3)	USEPA, 2011b
Dw	Diffusivity in water (cm^2/sec).	Chemical specific(3)	USEPA, 2011b
Koc	Soil organic carbon partition coefficient (cm^3/g).	Chemical specific(3)	USEPA, 2011b
foc	Fraction organic carbon in soil (g/g).	0.006	USEPA, 2002

Notes:
1 - Value is 14.31 for construction workers and 87.36898 for all other receptors evaluated.
2 - Value is 3.2E+07 for construction workers and 9.5E+08 for all other receptors evaluated.
3 - Chemical specific values are presented in Table 6-19.

Notes:
All values are from USEPA's Risk Assessment Guidance for Superfund Volume 1: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment) Final, July 2004.
1 - T(event) is 4 hours for the construction worker, 1 hour for hypothetical child residents, and 0.58 hours for hypothetical adolescent and adult residents.
FA = fraction absorbed water
Kp = dermal permeability coefficient of compound in water
T(event) = event duration
Tau = lag time
T* = time to reach steady-state
B = dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis
NA = not applicable

Notes:
1 - U.S. EPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Interim. EPA/540/R/99/005.
2 - Adjusted dermal RfD = Oral RfD x Oral Absorption Efficiency for Dermal.
3 - See text for BaP equivalent calculation methodology.
4 - Hexavalent chromium toxicity criteria are used to evaluate one percent of total chromium - see text.
5 - Adjusted IRIS value in accordance with recommendations on IRIS.

Definitions:
BaP = benzo(a)pyrene
CNS = central nervous system
CVS = cardiovascular system
GS = gastrointestinal system
HEAST = Health Effects Assessment Summary Tables
IRIS = Integrated Risk Information System
kg = kilogram
mg = milligram
NA = not available
RfD = reference dose
RSL = USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, June 2011.
PPRTV = Provisional Peer Reviewed Toxicity Value

Notes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum detected concentrations and as one sample when determining the frequency of detection and exceedanc
2 - Average of positive analytical results only.
3 - Average of all analytical results are calculated using half of the detection limit for nondetects.
4 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
5 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, June 2011.
The SSL at a DAF of 20 is 20x the SSL at a DAF of 1.
6 - The value is for xylenes.
7 - The value is for acenaphthene.
8 - The value is for pyrene.
9 - The value is for polychlorinated biphenyls (total).
10 - The value is for hexavalent chromium.

Defintions:
DAF = dilution attenuation factor
J = Estimated value
K = Biased high
kg = kilogram
MDE = Maryland Department of the Environment
mg = milligram
NC = No criteria
SSl = soil screening level
ug = microgram
USEPA = U.S. Environmental Protection Agency

1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum detected concentrations and as one sample when determining the frequency of detection and exceedances.
2 - Average of positive analytical results only.
3 - Average of all analytical results are calculated using half of the detection limit for nondetects.
4 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
5 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, June 2011.
6 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.
7 - The value is for hexavalent chromium.
8 - The value is for mercuric chloride (and other mercury salts).

Definitions:
J = Estimated value
MDE = Maryland Department of the Environment
NC = No criteria
RBC = risk based concentration
ug/L = microgram per liter
USEPA = U.S. Environmental Protection Agency

Notes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum detected concentrations and as one sample when determining the frequency of detection and exceedances.
2 - Average of positive analytical results only.
3 - Average of all analytical results are calculated using half of the detection limit for nondetects.
4 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
5 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, June 2011.
The SSL at a DAF of 20 is 20x the SSL at a DAF of 1.
6 - The value is for 1,4-dichlorobenzene.
7 - The value is for xylenes.
8 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.
9 - The value is for acenaphthene.
10 - The value is for pyrene.
11 - The value is for polychlorinated biphenyls (total).
12 - The value is for hexavalent chromium.
13 - Maximum Contaminant Level (MCL)-based soil screening level (SSL).

Definitions:
DAF = dilution attenuation factor
J = Estimated value
K = Biased high
kg = kilogram
L = biased low
MCL = Maximum Contaminant Level
MDE = Maryland Department of the Environment
mg = milligram
NC = No criteria
SSL = soil screening level
ug = microgram
USEPA = U.S. Environmental Protection Agency

Notes:
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum detected concentrations and as one sample when determining the frequency of detection and exceedances.
2 - Average of positive analytical results only.
3 - Average of all analytical results are calculated using half of the detection limit for nondetects.
4 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
5 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, June 2011.
The SSL at a DAF of 20 is 20x the SSL at a DAF of 1.
6 - The value is for xylenes.
7 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.
8 - The value is for acenaphthene.
9 - The value is for pyrene.
10 - The value is for polychlorinated biphenyls (total).
11 - The value is for hexavalent chromium.
12 - Maximum Contaminant Level (MCL)-based soil screening level (SSL).

Definitions:
DAF = dilution attentuation factor
J = Estimated value
kg = kilogram
L = Biased low
MCL = Maximim Contaminant Level
MDE = Maryland Department of the Environment
mg = milligram
NC = No criteria
REC = recognized environmental condition
SSL = soil screening level
ug = microgram
USEPA = U.S. Environmental Protection Agency

1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum detected concentrations and as one sample when determining the frequency of detection and exceedances.
2 - Average of positive analytical results only.
3 - Average of all analytical results are calculated using half of the detection limit for nondetects.
4 - State of Maryland Department of the Environment (MDE) Cleanup Standards for Soil and Groundwater, June 2008.
5 - USEPA Regional Screening Levels for Chemical Contaminants at Superfund Sites, June 2011.
6 - The screening level for trichloroethene was calculated using revised toxicity criteria from USEPA's Integrated Risk Information System.
7 - The value is for hexavalent chromium.
8 - The value is for mercuric chloride (and other mercury salts).

Definitions:
J = Estimated value
MDE = Maryland Department of the Environment
NC = No criteria
RBC = risk based concentration
REC = recognized environmental condition
USEPA = U.S. Environmental Protection Agency
ug/L = micrograms per liter

Human Health Conceptual Site Model
Greater Strawberry Point
Lockheed Martin, Martin State Airport
Middle River, Maryland

■ = POTENTIALLY COMPLETE EXPOSURE PATHWAY

1. Direct contact with subsurface soil (2 to 15 feet below ground surface) is not expected for industrial workers, trespassers, recreational users, and hypothetical residents. Direct exposure to subsurface soil would not be likely unless future construction activities brought subsurface soil to the surface. However, this pathway was evaluated to aid in risk-management decisions.

2. Exposure to surface water or sediment was not evaluated in this risk assessment.

Section 6
Ecological Risk Assessment

6.1 INTRODUCTION

This ecological risk assessment (ERA) aims to determine whether adverse ecological effects result from exposure to chemicals released to the environment through historical activities at Greater Strawberry Point (GSP) at the Martin State Airport (MSA) in Middle River, Maryland. This ERA presents information to enable risk managers to conclude whether ecological risks at the site are negligible, or if further information is necessary to evaluate these risks. The ERA methodology follows the guidance found in the following documents:

- *Final Guidelines for Ecological Risk Assessment* (U.S. Environmental Protection Agency [USEPA], 1998)
- *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (USEPA, 1997c)

This ERA consists of steps 1, 2, and 3a of an eight-step ERA process. The first two screening steps comprise the screening-level ecological risk assessment (SERA), where conservative exposure estimates are compared to screening-level values and threshold toxicity-values. Step 3a is the first step of a baseline ecological risk assessment (BERA), and consists of refining the conservative assumptions of Steps 1 and 2 to further focus the ERA process on the chemicals of greatest concern at a site. The remaining steps of the ERA process, that is, the rest of step 3 and steps 4–8, are not included in this ERA. This ERA evaluates recently collected data to characterize risks to ecological receptors.

6.2 PROBLEM FORMULATION

Problem formulation is the first phase in an ERA, and includes defining the goals, size, and focus of the assessment. It includes general descriptions of GSP at MSA, with an emphasis on the habitats and ecological receptors present. This phase also characterizes site-related chemicals, chemical sources, and migration routes, and evaluates routes of chemical exposure. The

assessment endpoints and measures of effects to be evaluated are also selected. Finally, a conceptual site-model (CSM) is developed describing how chemicals of interest associated with the subject site may contact ecological receptors.

6.2.1 Environmental Setting

This step initially identifies and characterizes the habitats and ecological resources throughout the site and identifies ecological receptors that could be adversely affected by chemicals from the site. GSP at MSA is a 75-acre site south of the main MSA terminal and southwest of the airport runway. The areas included in this ERA are an approximately 4.5-acre site (Recognized Environmental Conditions [RECs] #9 and #10), and an approximately two-acre site (REC #11). The sites are partially developed and are in a clearing between a wooded area and Taxiway F. This investigation focuses on GSP surface soil and groundwater seeps.

The RECs evaluated in the ERA mainly consist of cleared land with short-grass and no canopy or woody plants. A wooded area is adjacent to RECs #9, #10, and #11. Stansbury Creek is on the western edge of GSP. The eastern, southern, and western boundaries of MSA are bordered by Frog Mortar Creek and Stansbury Creek, which are wide, brackish, tidal tributaries of the middle Chesapeake Bay. Surface drainage from GSP is discharged via multiple outfalls to Stansbury Creek and Frog Mortar Creek. Groundwater in the surficial aquifer at GSP is expected to follow the surface topography and flow from the watershed divide near the airport runway area to the southwest and west (toward Stansbury Creek) and to the southeast (toward Frog Mortar Creek).

Suitable habitat for most ecological receptors is limited at the RECs evaluated in this ERA, as these disturbed sites consist of partially developed, cleared land. However, GSP also includes forest, field, and aquatic habitats that support ecological receptors. A variety of bird species are likely to frequent GSP, including geese, ducks (wading, diving, and wood ducks), herons, finches, sparrows, robins, warblers, hawks, eagles, kingfishers, and woodpeckers. Given the site's proximity to a surface water body (i.e., Stansbury Creek), its relative lack of human activity, and the range of habitats available, mammals, such as deer, fox, moles, shrews, rabbits, woodchucks, squirrels, and raccoons are also likely to be found on-site. Amphibians and reptiles are also likely to inhabit GSP, but for the most part screening-level effects data are unavailable to assess risks to these organisms.

6.2.2 Potential Sources of Contamination

Section 2 provides detailed background information regarding historical activities at GSP. The site was used by the Navy from the 1940s through 1960s for seaplane maintenance, launching, and recovery. Several naval weapons research and nuclear research buildings were on the site; aboveground storage tanks (ASTs) and underground storage tanks (USTs) were also present. Several USTs have been removed from the site, and no evidence of leakage was found. However, a known oil spill did occur during hanger construction in 1989–1990. Currently, the site has a tank farm with ASTs for jet fuel, gasoline, diesel fuel, and waste oil; an airport maintenance area; and several buildings used by the airport. Information regarding the toxicity, bioaccumulation potential (food-chain and trophic transfer), and fate and transport properties of chemicals detected at the site are in Appendix K-1.

6.2.3 Potential Exposure Pathways

Legacy chemicals resulting from historical site operations are today found primarily in the surface and subsurface soil, although chemicals may have migrated to groundwater after leaching from the soil. Chemicals in surface soil can enter the air via volatile organic compound (VOC) emissions or through wind erosion and dust. This pathway is unlikely because much of the site is vegetated, which limits the amount of dust produced.

Surface soil—For this ERA, the surface soil data-set consists of soil samples collected in the 0-2 feet and 1–3 feet below-grade interval. Several groups of terrestrial ecological receptors could be exposed to chemicals in surface soil. Soil-associated invertebrates such as earthworms are exposed to chemicals as they move through the soil and ingest soil particles as they forage. Plants are exposed to chemicals via direct contact; chemicals may also be absorbed through the roots and may translocate to different parts of the plants (e.g., leaves, seeds).

Small mammals may be exposed to chemicals in the soil via several exposure routes as they directly contact soil while foraging or burrowing through the soil. Exposure of terrestrial wildlife to chemicals in the soil via dermal contact is unlikely to represent a major exposure pathway because fur, feathers, scales, and chitinous exoskeletons are expected to minimize transfer of chemicals across dermal tissue. Small mammals have the greatest potential for exposure to chemicals in soil via incidental ingestion of soil and ingestion of food items, such as plants

and/or invertebrates that have accumulated chemicals from the soil. Carnivorous predatory species, including those with larger foraging ranges such as red fox and red-tailed hawk, can be indirectly exposed to site chemicals in soil by ingesting smaller animals that have accumulated chemicals from the soil and from contaminated food items.

Groundwater—Aquatic receptors are unlikely to be directly exposed to chemicals in groundwater. However, they can be indirectly exposed to chemicals in groundwater if the groundwater discharges to surface water. Aquatic vertebrates (such as fish and larval amphibians), benthic invertebrates, and adult amphibians, and reptiles can be exposed to contamination through direct contact and ingestion of surface water near groundwater discharge points. Groundwater data were collected as part of this investigation, and these data are used to conservatively evaluate receptor exposure to groundwater based on the assumption that aquatic receptors could be directly exposed to chemicals in groundwater at concentrations measured in groundwater.

6.2.4 Endpoints

Assessment endpoints—Assessment endpoints are an explicit expression of the environmental value to be protected (USEPA, 1997c). Selection of these endpoints is based on the habitats present, the chemicals' migration pathways, and the routes they may follow to exposure receptors. For this ERA, assessment endpoints include protecting the following groups of receptors from ecologically significant reductions in growth, survival, and/or reproduction due to exposure to site-related chemicals:

- soil invertebrates
- aquatic organisms
- invertivorous birds and mammals
- terrestrial vegetation
- herbivorous birds and mammals

The paragraphs below discuss why the following assessment endpoints were selected for this ERA:

Soil invertebrates: Soil invertebrates at the site help form soil, redistribute and decompose organic matter in the soil, and serve as a food source for higher, trophic-level organisms.

They can also accumulate some contaminants, which can then be transferred to the higher trophic-level organisms that consume soil invertebrates.

Terrestrial vegetation: Terrestrial vegetation at the site consists of grasses, shrubs, and trees. They serve as a food source, and provide shade, cover, and habitat for many organisms. They also help prevent soil erosion and serve other important functions. Vegetation can also accumulate some contaminants, which can then be transferred to the higher trophic-level organisms that consume plants.

Aquatic organisms: Aquatic organisms such as fish, invertebrates, and larval amphibians serve as a food source for higher trophic-level organisms (i.e., adult amphibians, reptiles, birds, mammals). Aquatic organisms can also accumulate contaminants, which can then be transferred to higher trophic-level organisms that consume them. Aquatic organisms are present in Stansbury Creek and Frog Mortar Creek.

Herbivorous birds and mammals: Herbivorous birds and mammals (e.g., animals that consume only plant tissue) are present at the site, due to its vegetative habitats (i.e., open field). Their role in the ecological community is essential, because without them, higher trophic-level organisms could not exist (Smith, 1966). They may be exposed to and accumulate contaminants that are in the plants they consume. These generally have smaller home and foraging ranges than larger carnivorous species.

Invertivorous birds and mammals: Invertivorous birds and mammals that primarily consume invertebrates are considered first-level carnivores. They are a food source for higher trophic-level carnivores, and may be exposed to, and accumulate chemicals from, the food items they consume. These species generally have smaller home and foraging ranges than larger carnivorous species.

USEPA guidance (USEPA, 1997c) states that "it is not practical or possible to directly evaluate risks to all of the individual components of the ecosystem at a site. Instead, assessment endpoints focus the risk assessment on particular components of the ecosystem that could be adversely affected by contaminants from the site." Therefore, this ERA focuses on the endpoints expected to yield the highest risks for exposed environmental receptors, thereby accounting for endpoints associated with lower risks.

Carnivorous birds and mammals generally have large home ranges. GSP covers approximately 75 acres, and the areas of the RECs evaluated are approximately 4.5 acres (RECs #9 and #10) and two acres (REC #11). When the size of the site is compared to the home range of higher trophic carnivores, such as the red-tailed hawk (whose range averages 1,692 acres) and the red fox (with an average range of 1,793 acres) (USEPA, 1993c), carnivores would only receive a very small portion of their diet from GSP. These carnivores are therefore not included as receptors in this ERA.

Threshold dietary or oral toxicity values for reptiles and amphibians are not available for most chemicals, so risks to reptiles and amphibians were not quantitatively evaluated. With these factors in mind, amphibians, reptiles, and carnivores were not retained as receptor groups associated with selected assessment endpoints. Instead, risks from bioaccumulation and biomagnification of contaminants are assessed for herbivorous and invertivorous birds and mammals.

***Measures of effects*—**Measures of effects or measurement endpoints are estimates of ecologically significant biological effects (e.g., reductions in or impairment of survival, growth, and/or reproduction) used to evaluate assessment endpoints. The following measures of effects were used to evaluate the assessment endpoints for this ERA:

- Ecologically significant decreases in survival, growth, and/or reproduction of plants, soil invertebrates, and aquatic biota were evaluated by comparing measured concentrations of chemicals in the surface soil and groundwater (used as proxy for and evaluated as surface water) to screening values designed to protect ecological receptors.

- Decreases in survival, reproduction, and/or adverse developmental effects in birds and mammals were evaluated by comparing the estimated ingested dose of contaminants in the surface soil to no observed adverse effects levels (NOAELs) and lowest observed adverse effects levels (LOAELs) for surrogate wildlife species.

6.2.5 Conceptual Site-Model

A CSM in ERA problem-formulation is a written description of predicted relationships between ecological entities and the stressors to which they may be exposed (USEPA, 1998). The CSM has two primary components: (1) predicted relationships among stressor, exposure, and assessment endpoint response, and (2) a diagram illustrating these relationships (USEPA, 1998). Figure 6-1 illustrates these relationships. At GSP, the primary source of chemicals originates in the soil,

although chemicals may have migrated to groundwater after leaching from the soil. Chemicals in groundwater may discharge as a seep that flows into surface water, or may discharge directly into a surface water body. However, groundwater discharging into Stansbury Creek or Frog Mortar Creek would be mixed with surface water and substantially diluted at the groundwater/surface water interface. Chemicals in soil can serve as a direct-exposure medium, but also can enter the air via emission of VOCs, or through wind erosion and dust. This pathway is unlikely, however, as the site is vegetated, which limits the amount of dust.

Aquatic organisms can be exposed to surface water by direct contact with and/or ingestion of surface water. Terrestrial plants, soil invertebrates, and terrestrial vertebrates can be exposed to chemicals in the surface soil by direct contact with and/or uptake (plants) and ingestion of soil and food items. Terrestrial vertebrates may also be exposed to volatile chemicals in the air via inhalation. Although this pathway is possible, it is considered insignificant and therefore is not evaluated in this ERA.

6.3 ECOLOGICAL EFFECTS EVALUATION

The preliminary ecological-effects assessment investigates the relationship between the exposure to a chemical and the potential for adverse effects resulting from that exposure. In this step, chemical-specific toxicity screening-levels for ecological receptors were compiled and selected for specific receptor groups. Receptor-group-specific screening levels are discussed below.

6.3.1 Terrestrial Plants and Invertebrates

Risks to terrestrial plants and soil-associated invertebrates from exposure to chemicals in site surface soil were evaluated by comparing chemical concentrations to ecological screening-levels. Selected screening levels include USEPA ecological soil-screening levels (Eco SSLs, for invertebrates, terrestrial plants, mammals and birds; [USEPA, 2003c, 2005c-k, 2006c, 2007a-g, 2008b]); Canadian soil-quality guidelines (SQGs; [CCME, 2006] and supporting documents from CCME, [1999a-d, 2001, 2004a-d, 2006a-b, 2010 and EC, 2001]); NOAA Screening Quick Reference Tables (Buchman, 2008); and USEPA Region 3 Biological Technical Assistance Group (BTAG) screening levels (USEPA, 1995). These toxicity values are expressed as chemical concentrations in soil because terrestrial plants and invertebrates are in direct contact with soil. Appendix K-1 contains the screening values and sources used in this ERA.

6.3.2 Aquatic Organisms

Risks to aquatic receptors from exposure to chemicals in groundwater via the surface water pathway were evaluated by comparing the chemical concentrations in groundwater to USEPA Region 3 *BTAG Freshwater Screening Benchmarks* and *Marine Screening Benchmarks* (USEPA, 2006a, b). These toxicity values are expressed as chemical concentrations in water because aquatic organisms are assumed to be in direct contact with surface water containing chemicals at concentrations measured in groundwater.

6.3.3 Terrestrial Wildlife

Risks to wildlife from exposure to chemicals in surface soil were determined by estimating chronic daily intake ([CDI]; an estimate of the average daily dose) using food-chain models, and comparing the CDI to dietary or dose-based toxicity reference-values (TRVs). Dietary TRVs represent regulatorily acceptable daily doses (in milligrams per kilogram body weight per day [mg/kg BW-day]). TRVs were developed from NOAELs and LOAELs obtained from wildlife studies. Most TRVs were obtained from the Oak Ridge National Laboratory (ORNL) *Toxicological Benchmarks for Wildlife: 1996 Revision* (Sample, et al., 1996), and USEPA's Eco SSL documents, supplemented with other toxicity information as necessary. Only chemicals that USEPA considers important bioaccumulative chemicals (USEPA, 2006a), or chemicals exceeding wildlife criteria (i.e., values based on dietary exposure of chemicals to mammals and birds), were included in the food-chain model.

Appendix K-1 presents the TRVs and sources of the NOAELs and LOAELs used in this ERA. If a subchronic study was used to develop the TRV, the final value was multiplied by a factor of 0.1 to account for uncertainty between subchronic and chronic effects. In addition, the LOAEL was multiplied by a factor of 0.1 to estimate a NOAEL TRV if only a LOAEL study was available. The chemical-specific Eco SSL documents provide both NOAELs and LOAELS for various chemicals based on multiple studies, but overall, TRVs are calculated only for NOAELs. The geometric mean of the chemical-specific growth and reproduction LOAELs from the chemical-specific Eco SSL documents were used as the LOAEL TRVs.

6.4 EXPOSURE CHARACTERIZATION

This portion of the ERA identifies contaminant concentrations used as exposure-point concentrations (EPCs) to represent ecological exposure in various media. EPCs are derived for surface soil and groundwater based on the conservative assumption of discharge to surface water without changes in concentration. GSP was divided into two exposure units, RECs #9 and #10 and REC #11, to evaluate risks to ecological receptors because these areas are separated by several hundred feet. Maximum chemical concentrations in exposure media from RECs #9 and #10 and REC #11 were used as the EPCs for the initial screening step. In accordance with USEPA (1993c), dissolved metal more closely approximates the bioavailable fraction of metal in the water column than total recoverable metal. Therefore, for metals, only the results in the filtered samples were evaluated for exposure to aquatic organisms.

As discussed above, the total exposure dose to terrestrial wildlife from chemicals in soil and food items such as plants and invertebrates was estimated using food-chain models. Selection of a particular species is required to estimate intake through ingestion. The availability of exposure parameters (e.g., body mass and ingestion rates) is a factor in selecting representative or surrogate species. The following receptors were selected for food-chain modeling:

- herbivorous mammal: meadow vole
- invertivorous mammal: short-tailed shrew
- herbivorous bird: bobwhite quail
- invertivorous bird: American robin

Receptor profiles for the surrogate species, including the exposure parameters used in the food-chain modeling, are included in Appendix K-2.

The following equation was used to calculate the CDI for wildlife receptors:

$$CDI = \frac{[(Cf * If) + (Cs * Is)] * H}{BW}$$

where:

CDI = chronic daily intake (mg/kg BW-day)

Cf = chemical concentration in food (mg/kg dry weight [dw])

Cs = chemical concentration in surface soil (mg/kg dw)

If = food ingestion rate (kilograms per day [kg/day dw])

Is = incidental surface soil ingestion rate (kg/day dw)

H = portion of food intake from the contaminated area (unitless)

BW = body weight (kg)

dw = dry weight

Chemical concentrations in soil and food items for invertivorous and herbivorous receptors were calculated using soil-to-invertebrate or soil-to-plant bioaccumulation factors (BAFs), regression equations from the USEPA Eco SSL guidance document (USEPA, 2007c), or other published sources. Sources of BAFs are documented in Appendix K-1. The following equation was used to calculate the chemical concentration in plants or invertebrates when BAFs are used:

$$Cf = Cs * BAF$$

where:

Cf = contaminant concentration in food (mg/kg dw)

Cs = contaminant concentration in surface soil (mg/kg dw)

BAF = biota-soil bioaccumulation factor (unitless)

Table 6-1 summarizes the exposure factors used in the food-chain model. Food ingestion rates were calculated on a dry-weight basis. The following input parameters were used in the dose equations under the conservative screening scenario:

- maximum surface-soil concentrations
- highest receptor-ingestion rates
- higher-end BAFs
- lowest receptor-body-weight

6.5 RISK CHARACTERIZATION

Risk characterization, the final phase of an ERA, compares exposure data to ecological effects data. This phase evaluates the likelihood that adverse effects will occur to a receptor from exposure to a stressor. An ecological-effects quotient (EEQ) approach was used to characterize risk to ecological receptors. EEQs greater than 1.0 indicate that ecological receptors could

potentially suffer adverse effects, and additional evaluation or data may be necessary to reduce uncertainties associated with risk estimates. Uncertainties can be high at this stage of the ERA process because most screening-level benchmarks are developed using conservative exposure assumptions. The EEQ value should not be construed as probabilistic; rather, it is a numerical indicator of the extent to which an EPC exceeds or falls short of a benchmark.

EEQs for surface soil receptors were calculated as follows:

$$EEQ = \frac{Css}{SSSL}$$

where:

EEQ = ecological effects quotient (unitless)

Css = chemical concentration in surface soil (micrograms per kilogram [µg/kg] or mg/kg, dw)

SSSL = surface soil screening-level (µg/kg or mg/kg)

EEQs for aquatic organisms were calculated as follows:

$$EEQ = \frac{Cgw}{SwSL}$$

where:

EEQ = ecological effects quotient (unitless)

Cgw = chemical concentration in groundwater (µg/L)

SwSL = surface water screening level (µg/L)

EEQs for wildlife were calculated as follows:

$$EEQ = \frac{CDI}{TRV}$$

where:

EEQ = ecological effects quotient (unitless)

CDI = chronic daily intake dose (mg/kg-day)

TRV = toxicity reference value (NOAEL or LOAEL) (mg/kg BW -day)

6.6 SELECTION OF CHEMICALS OF POTENTIAL CONCERN

The final step of the screening evaluation is selection of chemicals of potential concern (COPC). Chemicals not selected as COPC are assumed to present negligible risk to ecological receptors and were not considered for further evaluation in the ERA. Chemicals selected as COPC are evaluated further in Step 3a. Ecological COPC were selected using the following procedures:

- chemicals with initial screening level EEQs greater than 1.0 were selected as COPC for further evaluation because they could potentially pose risk to ecological receptors
- chemicals with EEQs greater than 1.0, based on the conservative food-chain model using NOAEL TRVs, were selected as COPC because they could potentially pose risk to mammals and birds. The LOAEL TRVs are used in the Step 3a refinement (discussed below).
- chemicals without screening values were selected as COPC, but were only evaluated qualitatively

6.6.1 Risks to Soil Invertebrates

Tables 6-2 and 6-3 present the occurrence, distribution, and selection of ecological COPC for soil invertebrates in the surface soil of GSP for RECs #9 and #10 and REC #11, respectively. The following summarizes COPC selection results for RECs #9 and #10 (Table 6-2):

- four VOCs were selected as COPC because a screening level was not available
- four semivolatile organic compounds (SVOCs) were selected as COPC: two because the maximum detected concentration exceeds the screening level, and two because a screening level was not available
- four inorganics were selected as COPC: three because the maximum detected concentration exceeds the screening level, and one because a screening level was not available.
- petroleum hydrocarbons (diesel-range organics) were selected as COPC because a screening level was not available

The following summarizes COPC selection results for REC #11 (Table 6-3):

- seven VOCs were selected as COPC because a screening level was not available

- five SVOCs were selected as COPC: one because the maximum detected concentration exceeds the screening level, and four because a screening level was not available

- three inorganics were selected as COPC: two because the maximum detected concentration exceeds the screening level, and one because a screening level was not available

- petroleum hydrocarbons (diesel-range organics and gasoline-range organics) were selected as COPC because a screening level was not available

6.6.2 Risks to Plants

Tables 6-2 and 6-3 present the occurrence, distribution, and selection of ecological COPC for plants in the surface soil of GSP for RECs #9 and #10, and REC #11, respectively. The following summarizes the selection of COPC for RECs #9 and #10 (Table 6-2):

- four VOCs were selected as COPC because a screening level was not available

- 16 SVOCs were selected as COPC: 13 because the maximum detected concentration exceeded the screening level, and three because a screening level was not available

- four inorganics were selected as COPC: three because the maximum detected concentration exceeds the screening level, and one because a screening level was not available

- petroleum hydrocarbons (diesel-range organics) were selected as COPC because a screening level was not available

The following summarizes the selection of COPC for REC #11 (Table 6-3):

- seven VOCs were selected as COPC because a screening level was not available

- 18 SVOCs were selected as COPC: 13 because the maximum detected concentration exceeds the screening level, and five because a screening level was not available

- three inorganics were selected as COPC: two because the maximum detected concentration exceeds the screening level, and one because a screening level was not available

- petroleum hydrocarbons (diesel-range organics and gasoline-range organics) were selected as COPC because a screening level was not available

6.6.3 Risks to Aquatic Organisms from Groundwater Evaluated as Surface Water

Tables 6-4 and 6-5 present the occurrence, distribution, and selection of ecological COPC for groundwater evaluated as surface water from GSP for RECs #9 and #10, and REC #11, respectively. Groundwater discharging into water bodies as large as Stansbury Creek or Frog Mortar Creek would be expected to be substantially diluted at the groundwater/surface-water interface. Therefore, Tables 6-4 and 6-5 also present groundwater concentrations with a range of dilution factors considered reasonably representative of possible levels of dilution (i.e., 10-, 25-, and 50-fold).

The following summarizes the results of the COPC selection with no dilution factor applied to chemical concentrations measured in groundwater for RECs #9 and #10:

- Three VOCs were selected as COPC: two because the maximum detected concentration exceeds the screening level, and one (tertiary-butyl alcohol) because a screening level was not available
- 12 inorganics in filtered samples were selected as COPC because the maximum detected concentration exceeds the screening level
- petroleum hydrocarbons (diesel-range organics and gasoline-range organics) were selected as COPC because a screening level was not available

The following summarizes the results of the COPC selection with no dilution factor applied to chemical concentrations measured in groundwater for REC #11:

- one VOC was selected as a COPC because the maximum detected concentration exceeds the screening level.
- one SVOC was selected as a COPC because a screening level was not available
- 12 inorganics in filtered samples were selected as COPC because the maximum detected concentration exceeds the screening level
- petroleum hydrocarbons (diesel-range organics) were selected as COPC because a screening level was not available

6.6.4 Risks to Terrestrial Wildlife from Surface Soil via Food-Chain Modeling

Tables 6-2 and 6-3 list chemicals selected for food-chain modeling for RECs #9 and #10, and REC #11, respectively. Tables 6-6 and 6-7 summarize EEQs for the conservative food-chain

model for RECs #9 and #10, and REC #11, respectively. Appendix K-3 contains spreadsheets with EEQ calculations for each receptor. Chemicals were selected as COPC if their calculated NOAEL EEQs were greater than 1.0 for any receptor.

The following sections summarize the results of the COPC selection for REC #9 and #10:

- *herbivorous mammal:* two polycyclic aromatic-hydrocarbons (PAHs) and three inorganics had EEQs greater than 1.0 in the food-chain model
- *herbivorous bird:* three PAHs and three inorganics had EEQs greater than 1.0 in the food-chain model
- *invertivorous mammal:* eight PAHs and four inorganics had EEQs greater than 1.0 in the food-chain model
- *invertivorous bird:* 13 PAHs and four inorganics had EEQs greater than 1.0 in the food-chain model

The following sections summarize the results of the COPC selection for REC #11:

- *herbivorous mammal:* one PAH and three inorganics had EEQs greater than 1.0 in the food-chain model
- *herbivorous bird:* three inorganics had EEQs greater than 1.0 in the food-chain model
- *invertivorous mammal:* seven PAHs, one PCB, and six inorganics had EEQs greater than 1.0 in the food-chain model
- *invertivorous bird:* five PAHs, one PCB, and five inorganics had EEQs greater than 1.0 in the food-chain model

6.7 STEP 3A: COPC REFINEMENT

Step 3a refines the conservative exposure-assumptions and concentrations to evaluate risks to ecological receptors (i.e., plants, invertebrates, aquatic biota, and wildlife receptors). The Step 3a evaluation further refines the number of chemicals retained as COPC to focus additional effort on chemicals of major ecological concern, based on the criteria presented below. The following describes this further evaluation of chemicals initially selected as COPC in soil and groundwater.

The following criteria were evaluated, as appropriate, to determine if chemicals identified as COPC in the initial screening-level steps of the ERA warrant additional evaluations. (Note that not all of these factors are necessarily discussed for each chemical and/or receptor group.)

- *Magnitude of criterion exceedance*: Although the magnitude of the risks may not relate directly to the magnitude of a criterion exceedance, the magnitude of the criterion exceedance may be one item used in a lines-of-evidence approach to determine the need for further site evaluation. The greater the criterion exceedance, the greater the probability and concern that a regulatorily unacceptable risk exists.

- *Frequency of chemical detection and spatial distribution*: A chemical infrequently detected typically is of less concern than a chemical detected at higher frequency if toxicity, concentrations, and spatial areas represented by the data are similar. All else being equal, chemicals detected frequently were given greater consideration than those detected relatively infrequently. In addition, the spatial distribution of a chemical may be evaluated to determine the area that a given sample represents.

- *Contaminant bioavailability*: Many contaminants (especially inorganics) are present in the environment in forms that are typically not bioavailable, and this limited bioavailability was considered when evaluating receptor exposures to site contaminants. Contaminants with generally less bioavailability are considered less toxic than the more bioavailable contaminants, all other factors being equal.

- *Habitat*: Although exceedances of criteria may be identified, risks to ecological receptors may be minimal if little habitat exists for those receptors. Therefore, the extent of habitat was used qualitatively in considering additional evaluation. Areas with little habitat were of less concern than areas with suitable habitat to support the receptors of interest.

- *More appropriate benchmarks* were used to further evaluate risks to specific groups of ecological receptors (e.g., plants, invertebrates, and benthic organisms), because although screening levels are useful for initial screening, they are very conservative and may be inappropriate for evaluating all assessment endpoints.

- *Background*: Concentrations of chemicals in surface soil were compared anticipated typical concentrations (ATC) for eastern Maryland, as presented in State of Maryland Department of the Environment *Cleanup Standards for Soil and Groundwater* (June 2008).

- *Food-chain modeling*: Dietary exposure via the food chain is a major pathway of concern for chemicals known to significantly bioaccumulate and/or biomagnify. Thus, potential risk to upper-trophic-level receptors was evaluated using food-chain models. The conservative exposure doses initially calculated at the screening level step of the ERA for terrestrial wildlife were recalculated using less conservative exposure-assumptions and chemical concentrations.

Note that diesel-range organics (DRO) and gasoline-range organics (GRO) were initially selected as COPC because they lack ecological screening-levels. However, because the soil samples were analyzed for PAHs and VOCs, which are major components of DRO and GRO, risks from diesel-range organics and gasoline-range organics are evaluated indirectly by evaluating risks

from the individual PAHs and VOCs. Therefore, risks from diesel-range organics and gasoline-range organics are not discussed below and these compounds are not retained as COPC.

6.7.1 Risks to Soil Invertebrates and Plants

The first step in the Step 3a evaluation compares a maximum chemical concentration in soil to screening benchmarks specific to plants and invertebrates. This is because the Region 3 BTAG soil-screening levels are understood to be the lowest values available for plants, invertebrates, or wildlife, but the actual basis for some of these values is either not known or may not be based on plants or invertebrates. Chemicals with concentrations greater than the appropriate plant or invertebrate benchmark (or chemicals that do not have a benchmark) are further evaluated in Step 3a to determine if the risks they pose are sufficient to warrant additional evaluations.

6.7.1.1 Soil Invertebrates

Several VOCs, SVOCs, inorganics, and petroleum hydrocarbon were initially selected as COPC for soil invertebrates in GSP surface soil for RECs #9 and #10, and REC #11.

VOCs—1,2,3-Trimethylbenzene, 1,2,4-trimethylbenzene, 2-butanone, 4-methyl-2-pentanone, acetone, carbon disulfide, n-propylbenzene, and tertiary-butyl alcohol were initially selected as COPC in surface soil because screening levels are not currently available. These chemicals have been detected at relatively low concentrations (i.e., less than 10 µg/kg, except for acetone). 1,2,4-Trimethylbenzene, 2-butanone, carbon disulfide, and n-propylbenzene have been detected at low frequencies (≤6% for these chemicals) (see Tables 6-2 and 6-3). VOCs are typically not very toxic to invertebrates via direct contact, and screening levels for other VOCs are typically high (e.g., USEPA Region 3 surface soil screening-level [SSSL] for many VOCs are 100 or 300 µg/kg). Canadian Soil-Quality Guidelines for VOCs are over 1,000 µg/kg (CCME, 2006a). Acetone and 2-butanone are also common or possible laboratory contaminants. For these reasons, the aforementioned VOCs are not retained as chemicals of ecological concern for soil invertebrates, and do not warrant further evaluation at this site.

SVOCs—Toxicity data for soil invertebrates were not available for carbazole and dibenzofuran detected in RECs #9 and #10, and REC #11 and for caprolactam and n-nitroso-di-n-propylamine detected in REC #11, so their effects could not be evaluated quantitatively. Caprolactam and n-nitroso-di-n-propylamine were detected in only one of 32 samples from REC #11. Carbazole

and dibenzofuran, which tend to be associated with PAHs, were detected at GSP at concentrations less than PAHs and they are not expected to be more toxic than PAHs. Therefore, risks from these chemicals, if any, should be accounted for in the evaluation of risks from PAHs. The maximum concentrations of these SVOCs (2,000 µg/kg) are much lower than the soil invertebrate Eco SSLs for PAHs (18,000 µg/kg (high molecular-weight PAHs) and 29,000 µg/kg (low molecular-weight PAHs)). Therefore, carbazole, dibenzofuran, caprolactam, and n-nitroso-di-n-propylamine are not expected to adversely affect soil invertebrates at this site, and do not warrant further evaluation.

Butyl benzyl phthalate was selected as a COPC for REC #11 because the maximum concentration (250 µg/kg) exceeds the screening level (100 µg/kg). The toxicological basis of this screening value is not known. Although an alternative benchmark is not available for this specific phthalate, other phthalates are toxic to invertebrates at concentrations much greater than those detected at Greater Strawberry Point. For example, the ORNL soil-invertebrate toxicological benchmark (Efroymson et al., 1997a) for dimethylphthalate is 200,000 µg/kg. Butyl benzyl phthalate was detected in only one of 32 samples, so it is not expected to be toxic to soil invertebrates at the detected concentration and is not retained as a COPC for this receptor group.

Two individual PAHs (fluoranthene and pyrene) were selected as COPC for RECs #9 and #10. Only one sample (SB-68 in REC #10, southwest of Building 029) had detected concentrations of fluoranthene (33,000 µg/kg) and pyrene (34,000 µg/kg) exceeding their screening values of 29,000 µg/kg and 18,000 µg/kg, respectively. The EEQs were slightly greater than one for fluoranthene (1.1) and pyrene (1.9) for soil invertebrates. Adjacent samples had concentrations of these constituents below screening values, suggesting the area associated with risk from these chemicals is small. Adverse effects to individual organisms would likely be minimal, and adverse population and community-level effects are highly unlikely, so PAHs are eliminated as COPC for soil invertebrates.

***Inorganics*—**Iron and manganese were selected as COPC for REC #11 because maximum concentrations exceed screening levels. Iron, manganese, molybdenum, and thallium were selected as COPC for RECs #9 and #10 because maximum concentrations exceed screening levels. Silver was selected as a COPC for RECs #9 and #10 and REC #11 because a screening level was not available.

Iron was selected as a COPC because it was detected at a concentration in excess of its screening value of 200 mg/kg, based on adverse effects to exposed soil microorganisms. The distribution of iron across the site does not suggest a pattern that would indicate a specific source of iron. The maximum iron concentrations in RECs #9 and #10 (12,900 mg/kg) and REC #11 (15,000 mg/kg) are less than or equal to the State of Maryland (2008) anticipated typical concentration (ATC) for iron (15,000 mg/kg). Average iron concentrations in RECs #9 and #10 (6,933 mg/kg) and REC #11 (8,240 mg/kg) are much lower than the Maryland ATC for iron. Iron is typically not considered bioavailable and is rarely implicated as a toxic metal under most conditions. Therefore, adverse effects from iron are expected to be minimal and not site-related, and it is eliminated as a COPC for soil invertebrates.

Manganese was selected as a COPC for RECs #9 and #10 and REC #11 because the maximum detected concentrations exceed the Eco SSL for soil invertebrates (450 mg/kg). The average manganese concentrations for RECs #9 and #10 (398 mg/kg) and REC #11 (175 mg/kg) are less than the screening level. Manganese concentrations exceed the screening value in samples collected from SB-62 (864 mg/kg), SB-63 (1,590 mg/kg), and SB-71 (2,390 mg/kg) from RECs #9 and #10. Samples from SB-62 and SB-63 in RECs #9 and #10 were collected adjacent to a road. The sample from SB-71 was collected northwest of REC #10, and adjacent samples were not analyzed for manganese. Only the maximum concentration of manganese from SB-84 in REC #11 (1,050 mg/kg) exceeds its screening value.

In REC #11, adjacent samples to the northeast and northwest of sampling location SB-84 detected manganese concentrations well below the screening value. Samples collected south of SB-84 in REC #11 were not analyzed for manganese; however, the sample from SB-84 was bounded to the southeast by an adjacent road. Adverse effects from manganese are expected to be minimal at REC #11, so manganese is eliminated as a COPC for soil invertebrates at REC #11. Potential adverse effects on soil invertebrates from manganese at RECs #9 and #10 are possible, and the greatest detected concentration is not bounded; therefore, manganese is retained as a COPC for soil invertebrates at REC #9 and #10.

Molybdenum was selected as a COPC for RECs #9 and #10 because the maximum concentration detected (1 mg/kg) exceeds the Region 3 screening level (0.59 mg/kg); however, the receptor upon which this value is based was not reported. Screening levels for molybdenum in soil are

few and confidence is low in the ability of the few available screening levels to assess the potential for adverse ecological effects. Several detected concentrations of molybdenum exceed its screening level. An alternative value for soil invertebrates was not available; however, concentrations are well below the ORNL value for soil microorganisms of 200 mg/kg (Efroymson, et al., 1997a). Therefore, risks to soil invertebrates from molybdenum are expected to be minimal, and molybdenum is eliminated as a COPC for soil invertebrates.

Silver was selected as a COPC for RECs #9 and #10 and REC #11 because no screening level for soil invertebrates was available. Although no benchmark for invertebrates was available, the ORNL benchmark concentration for soil microorganisms is 50 mg/kg (Efroymson et al., 1997a). Maximum concentrations of silver in RECs #9 and #10 (0.38 mg/kg) and REC #11 (0.49 mg/kg) are well below this value. Concentrations of silver are also less than the Maryland (2008) ATC for silver (0.94 mg/kg). Risks to soil invertebrates from silver are likely minimal and not site-related, so silver is not retained as a COPC for this receptor.

Thallium was selected as a COPC for RECs #9 and #10 because the maximum concentration detected (2.3 mg/kg) slightly exceeds the screening value of 1.4 mg/kg. Thallium was detected infrequently in three of 33 samples with only two samples exceeding the screening value. The maximum concentration of thallium in RECs #9 and #10 is less than the Maryland (2008) ATC for thallium (3.9 mg/kg). Risks to soil invertebrates from thallium are therefore likely minimal and not site-related, so thallium is not retained as a COPC for this receptor.

6.7.1.2 Plants

VOCs—1,2,3-Trimethylbenzene, 1,2,4-trimethylbenzene, 2-butanone, 4-methyl-2-pentanone, acetone, carbon disulfide, n-propylbenzene, and tertiary-butyl alcohol were initially selected as COPC in surface soil because screening levels are not currently available, but these VOCs were eliminated as COPC for plants for reasons similar to those presented for eliminating them as COPC for soil invertebrates.

SVOCs—Carbazole, dibenzofuran, caprolactam, and n-nitroso-di-n-propylamine were initially selected as COPC in surface soil because screening levels are not currently available, but these SVOCs were eliminated as COPC for plants for similar reasons to those presented for eliminating them as COPC for soil invertebrates. Several PAHs (2-methylnaphthalene,

acenaphthylene, anthracene, benzo[a]anthracene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluorene, indeno[1,2,3-cd]pyrene, naphthalene, phenanthrene, and pyrene) were selected as COPC for plants because the maximum detected concentrations exceed their screening level (100 µg/kg), or because no screening level was available (2-methylnaphthalene).

The screening level of 100 µg/kg for these PAHs is based on their effects on mice; no Eco SSL is available for plants. However, data in Table 3.1 of the Eco SSL document for PAHs (USEPA, 2007e) show that PAHs are typically not toxic to plants except at high soil concentrations, with the lowest listed EC_{50} being 30,000 µg/kg from Mitchell, et al. (1988). In addition, seed germination and growth were not affected in agricultural soils spiked with benzo(a)pyrene, benz(a)anthracene, or dibenz(a,h)anthracene concentrations in the range of 31,000–155,000 µg/kg (CCME, 2010). All of the detected concentrations of individual PAHs are much less than 155,000 µg/kg, and most are less than 30,000 µg/kg. Thus, PAHs in the soil are unlikely to adversely affect plants. Risks to plants are therefore regulatorily acceptable, and PAHs are not retained as COPC for risks to this receptor.

Inorganics—Iron was selected as a COPC for RECs #9 and #10 and REC #11 because a screening level was not available. Manganese and selenium were selected as COPC for REC #9 and #10 because the maximum concentration exceeds the screening level. Manganese, selenium, and thallium were selected as COPC for REC #11 because the maximum concentration exceeds the screening level.

Iron was selected as a COPC because soil pH data were not available. The USEPA Eco SSL guidance for iron (USEPA, 2003c) indicates that the toxicity of iron in surface soil is directly related to soil pH. Iron is expected to be toxic only at a pH less than 5 or greater than 8. Although pH data at the site were not available, iron is typically not bioavailable in surface soils. In addition, the maximum iron concentration in RECs #9 and #10 and REC #11 is less than or equal to the Maryland (2008) ATC for iron of 15,000 mg/kg. The presence of iron is not likely attributable to site-related activities. Therefore, iron is unlikely to be toxic to plants and is not retained as a COPC for this receptor.

Manganese was selected as a COPC because concentrations in several samples from RECs #9 and #10 and REC #11 exceed the Eco SSL for plants (220 mg/kg). The average manganese concentration (398 mg/kg) from RECs #9 and #10 is greater than the screening value. Detected manganese concentrations exceed the screening level in four samples from RECs #9 and #10: SB-62 (864 mg/kg), SB-63 (1,590 mg/kg), SB-67 (417 mg/kg), and SB-71 (2,390 mg/kg). Sampling locations SB-62, SB-63, and SB-67 in RECs #9 and #10 are adjacent to a road; location SB-71 is northwest of REC #10, and adjacent samples were not analyzed for manganese.

The average manganese concentration (175 mg/kg) from REC #11 is less than the screening value. Manganese exceeds its screening level in two samples from REC #11: SB-84 (1,050 mg/kg) and SB-87 (323 mg/kg). Sampling location SB-84 is adjacent to a road, and adjacent samples had manganese concentrations below the screening value. Sampling location SB-87 is in the northeastern corner of REC #11, bounded by two roads to the north and east. Risks to plants from manganese concentrations at REC #11 are expected to be minimal, and manganese is eliminated as a COPC for plants at REC #11. Adverse effects on plants from exposure to manganese in soil at RECs #9 and #10 cannot be ruled out, and the greatest detected concentration is not bounded; therefore, manganese is retained as a COPC for plants at RECs #9 and #10.

Selenium was selected as a COPC because the maximum concentration detected in RECs #9 and #10 (1.2 mg/kg) and REC #11 (3.1 mg/kg) exceeds the Eco SSL for plants (0.52 mg/kg). Many samples collected from GSP had detected concentrations of selenium exceeding the Eco SSL. However, the ATC for selenium for eastern Maryland is 2.2 mg/kg (State of Maryland, 2008). The only selenium concentration exceeding this background level is the maximum detected concentration in REC #11. Therefore, site-related risks to plants from selenium are likely minimal, and selenium is not retained as a COPC for this receptor.

Thallium was selected as a COPC for RECs #9 and #10 because the maximum concentration detected (2.3 mg/kg) slightly exceeds its screening value of 1.4 mg/kg. Thallium was detected infrequently in three of 33 samples, with only two exceeding the screening value. In addition, the maximum concentration of thallium in RECs #9 and #10 is less than the Maryland (2008) ATC

for thallium (3.9 mg/kg). Therefore, risks to plants from thallium are likely minimal and not site-related, and thallium is not retained as a COPC for this receptor.

6.7.2 Risks to Aquatic Organisms from Groundwater Evaluated as Surface Water

Several VOCs, one SVOC, filtered inorganics, and petroleum hydrocarbons were initially selected as COPC for aquatic organisms in groundwater (which was evaluated using surface water screening levels). Table 6-4 and 6-5 includes EEQs for chemicals detected in groundwater, with a range of assumed reasonable dilution-factors applied. When a dilution factor of 25-fold is applied, only dissolved barium and iron exceed surface water criteria for RECs #9 and #10; no chemicals exceed surface water criteria at a dilution factor of 50-fold. No screening levels were available for the tertiary-butyl alcohol detected in groundwater from RECs #9 and #10; therefore, tertiary-butyl alcohol cannot be evaluated for ecological risk.

When a dilution factor of 25-fold is applied to REC #11 chemical concentrations, only dissolved barium, iron, and nickel exceed surface water criteria. Maximum concentrations of dissolved iron exceed surface water criteria at a dilution factor of 50-fold for REC #11, using the 300 µg/L freshwater value (USEPA, 2006a) as the screening level. The average concentrations of dissolved iron from REC #11 do not exceed the Region 3 BTAG screening level (300 µg/L) if a dilution of 50-fold is applied. The BTAG screening level is based on a Canadian Water Quality Guideline, however, the chronic USEPA National Recommended Water Quality Criteria for iron is 1,000 µg/L (USEPA, 2009b). If the National Recommended Water Quality criterion for iron is used as the screening level, assuming a 25-fold dilution factor, the maximum concentrations of dissolved iron for REC #11 do not exceed the criterion. As stated earlier, iron concentrations in soil are not believed to be site-related.

No screening levels were available for caprolactam detected in groundwater from REC #11; therefore, caprolactam cannot be evaluated for ecological risk. However, because groundwater discharging into Stansbury Creek or Frog Mortar Creek would be diluted many times at the groundwater/surface-water interface, potential risks to aquatic biota from this and other analytes with exceedances are likely minimal; therefore, no chemicals are retained as COPC for risks to this receptor group.

6.7.3 Calculated Risks from Surface Soil to Terrestrial Wildlife via Food-Chain Modeling

As discussed earlier in Section 6.6.6, dietary EEQs calculated using terrestrial food-chain modeling are greater than 1.0 for several chemicals, if maximum chemical concentrations and conservative exposure-assumptions are used. Therefore, as part of the Step 3a refinement, risks were recalculated using average chemical concentrations and the (Step 3a) exposure parameters presented in Table 6-1. The parameters used are summarized in the exposure-factors calculation table in Appendix K-2. Food-chain-model calculation-sheets are in Appendix K-3. The following decisions are based on the results of the food-chain model:

- if the EEQ (calculated using average contaminant concentrations, average exposure factors, and the NOAEL as the TRV) is less than 1.0, we concluded that the chemical is not causing a regulatorily unacceptable risk to wildlife, and the chemical was not evaluated further in Step 3a

- if the EEQ is greater than 1.0 (using average contaminant concentrations, average exposure factors, and the NOAEL as the TRV), the chemical is further evaluated in Step 3a to determine if the associated risks are sufficient to warrant additional evaluations

Using the conservative food-chain model for GSP, several PAHs and metals from RECs #9 and #10 and REC #11, and PCBs from REC #11, were selected as COPC for wildlife because the modeled EEQs were greater than 1.0 for at least one surrogate receptor under the conservative exposure scenario. Tables 6-8 and 6-9 present the results of the less conservative food-chain model for RECs #9 and #10 and REC #11, respectively.

The results of the less-conservative food-chain modeling for terrestrial receptors at RECs #9 and #10 are summarized in Table 6-8. A discussion of risks to mammals and birds, based on these results, follows:

- *soil herbivorous receptors:* All EEQs were less than 1.0 using the NOAEL as the TRV

- *soil invertivorous receptors:* Using the NOAEL as the TRV, calculated EEQs for the shrew for iron (12) and thallium (3.6) were greater than 1.0, as were the iron (11) and mercury (8.3) EEQs modeled for the robin. All LOAEL EEQs modeled for these receptors, except for iron, were less than 1.0. The iron EEQs for the shrew (1.2) and robin (1.1) were only slightly greater than 1.0 using the LOAEL as the TRV. Earthworm BAFs are not available for iron and thallium, so a default value of 1.0 was used to estimate chemical concentrations in earthworms for the invertivorous-receptor food-chain model. This likely overestimates the dose of soil that invertivorous receptors ingest through food.

Iron and thallium are not typically considered bioaccumulative, so the actual accumulation of iron and thallium in earthworms is likely much lower based on BAFs of less than 1.0 for most metals. The Maryland (2008) ATC for mercury (0.51 mg/kg) is greater than the maximum concentration (0.16 mg/kg) at RECs #9 and #10; if the ATC is used as the soil-mercury concentration, it would produce an EEQ >1.0. Maximum concentrations of iron, thallium, and mercury are less than Maryland (2008) ATCs; therefore, potential risks are not site-related. For these reasons, iron, thallium, and mercury were eliminated as COPC for soil invertivorous-receptors for RECs #9 and #10.

Table 6-9 summarizes the results of the less-conservative food-chain modeling for terrestrial receptors for REC #11. A discussion of risks to mammals and birds based on these results follows:

- *soil herbivorous receptors:* All EEQs were less than 1.0 using the NOAEL as the TRV

- *soil invertivorous receptors:* The EEQs for Aroclor-1260 (8.0), iron (15), mercury (1.2), and thallium (2.6) for the shrew were greater than 1.0 using the NOAEL as the TRV. The EEQs for Aroclor-1260 (5.1), iron (13), and mercury (9.8) for the robin were greater than 1.0 using the NOAEL as the TRV. All LOAEL EEQs for both receptors, except for iron, were less than 1.0.

  The iron EEQs for the shrew and robin (1.5 and 1.3, respectively) were slightly greater than 1.0 using the LOAEL as the TRV. Iron and thallium are not considered bioaccumulative, and, as described above, earthworm BAFs are not available. Therefore, the exposure dose for these metals is likely overestimated. The Maryland (2008) ATC for mercury (0.51 mg/kg) is greater than the maximum concentration (0.3 mg/kg) at REC #11; using the ATC as input into the model would produce an EEQ greater than 1.0. Maximum concentrations of iron, thallium, and mercury were less than or equal to Maryland ATCs (State of Maryland, 2008); therefore, risks are not due to site-related activities. For these reasons, iron, mercury, and thallium were eliminated as COPC for soil invertivorous-receptors for REC #11.

  Aroclor-1260 exceeds its screening value (1,300 µg/kg) in six of 33 samples. The EEQ of 8.0 for the shrew is based on comparisons of the calculated dose to the NOAEL; the EEQ based on the LOAEL was less than 1.0. The elevated Aroclor-1260 concentrations were in samples near Building 036, and along the northern boundary of REC #11. However, the extent of Aroclor-1260 contamination has not been determined to the southwest along the taxiway; whether contamination extends across the taxiway is unknown. For these reasons, Aroclor-1260 was retained as a COPC for invertivorous mammalian receptors and invertivorous avian receptors for REC #11.

6.8 ECOLOGICAL RISK UNCERTAINTY ANALYSIS

This section discusses some of the uncertainties associated with the GSP ERA.

6.8.1 Measurement and Assessment Endpoints

Measures of effects (i.e., measurement endpoints) were used to evaluate selected assessment endpoints. These measures evaluate the attainment of assessment endpoints such as protection of soil-associated invertebrates from adverse effects on their survival, growth, or reproduction. For example, risks to shrews based on toxicity thresholds or other similar data are assumed applicable to other small mammals. In this example, the shrew is used as a surrogate to assess a decrease in reproduction that can result in reduced small mammal populations. This approach may result in under- or over-protection of other unassessed small mammal species, due to differences in species' sensitivity to contaminants, ingestion rates, diet, home ranges, etc. Risks to reptiles and amphibians were not quantitatively evaluated in this ERA because toxicity data are mostly lacking for these organisms, and exposure factors have not been established for most species. Risks to carnivorous wildlife with larger foraging ranges were not determined, for the reasons discussed previously.

6.8.2 Exposure Characterization

Uncertainty exists in the chemical data collected at the site. Measured levels of chemicals are only estimates of the true chemical concentrations in site media. Sampling data for naphthalene was reported in both the VOC and SVOC fractions. To be conservative, all data for naphthalene are presented.

Direct contact—Highly bioavailable forms of chemicals are typically used in toxicity tests; the bioavailability of contaminants in environmental media is likely less. In addition, bioaccumulation of contaminants depends on characteristics of the abiotic media, such as pH, organic carbon, etc. Therefore, the actual toxicity of chemicals to which receptors (e.g., plants and invertebrates) are exposed by direct contact with contaminated media is likely overestimated.

Food-chain modeling—The average daily contaminant-dose for terrestrial wildlife is calculated using an equation that incorporates ingestion rates, body weights, BAFs, and other exposure factors. Bioaccumulation of contaminants into various biological media (e.g., plants, invertebrates, and small mammals) depends on characteristics of the abiotic media, such as pH, organic carbon, etc. Therefore, site-specific BAFs likely differ from those obtained from

literature and used to calculate risk in the ERA. For example, the BAF used for the earthworm for iron and thallium defaults to the value of 1.0. This likely overestimates the dose ingested in food eaten by soil invertivorous-receptors; the actual accumulation of iron and thallium in earthworms is probably much lower, since earthworm BAFs for most other metals are lower.

No avian TRVs for butyl benzyl phthalate, antimony, and thallium are available, so risks to birds from these chemicals could not be evaluated using the food-chain model. In addition, the PAH TRV for birds is based on 7,12-dimethylbenz(a)anthracene. Using this TRV as proxy for all PAH calculations introduces additional uncertainty. Furthermore, highly bioavailable forms of chemicals are typically used in dosing studies for wildlife; the bioavailability of contaminants in environmental media is likely less. Ingestion rates and body weights vary within and among species; this is especially true for species inhabiting different areas.

The exposure factors used in the food-chain model were obtained from studies in the scientific literature or were predicted using various equations, and thus may not be representative of on-site receptors. The actual exposure of ecological receptors to chemical contaminants is likely overestimated. In particular, wildlife with a large home range will typically roam over multiple sampling locations and would not be expected to obtain all of their food from the most contaminated areas at GSP.

6.8.3 Ecological Effects Data

Several alternative benchmark values were used to better understand the relationship between COPC concentrations and potential effects on ecological receptors. Some uncertainty is involved in using some of the conservative screening levels, because the toxicological basis of some of those numbers is not known. Alternative benchmarks, however, lessen these uncertainties because they are specific for the receptors being evaluated. Some uncertainty is also inherent in using background values.

6.8.4 Risk Characterization

Risks are deemed regulatorily unacceptable and adverse effects in exposed receptors are possible if a calculated EEQ is greater than or equal to 1.0, regardless of the magnitude of the EEQ. The magnitude of effects on ecological receptors cannot be inferred based on the magnitude of the EEQ. Rather, an EEQ greater than 1.0 simply indicates that the selected toxicity reference-value

was exceeded. Finally, uncertainty exists in whether or not adverse effects would occur at only the individual organism level or at the population or community level. Evaluating potential population-level effects are the focus of the ERA, unless protected (e.g., threatened and endangered) species are a site-specific concern.

6.9 ECOLOGICAL RISK SUMMARY AND CONCLUSIONS

A screening-level ecological risk assessment (SERA) was performed for GSP. The results of the initial screening for surface soil and groundwater (evaluated as surface water) resulted in several chemicals being selected as COPC for the site. These chemicals were evaluated further in the Step 3a refinement (the first step of the baseline ecological risk assessment [BERA]). The initial list of COPC was refined after a review of alternative toxicity information, the spatial distribution of contaminants, magnitude of criteria exceedances, background concentrations, and dilution factors (with respect to groundwater COPC). This section summarizes the conclusions of the ERA conducted for RECs #9 and #10 and REC #11 at GSP.

Manganese in surface soil was retained as a COPC for soil invertebrates and plants at RECs #9 and #10. The greatest detected concentration of manganese, which exceeds the screening values for soil invertebrates and plants, was not bounded; therefore, the size of habitat affected by elevated manganese concentrations is not known. Although the bioavailability of manganese in soil is not known, manganese in the environment is probably lower than the bioavailability of the manganese in soil at the site. Therefore, even though the extent of the manganese contamination is not bounded, its effect on plant and invertebrate communities at the site is probably not significant.

Aroclor-1260 in surface soil was retained as a COPC for birds and mammals at REC #11. Aroclor-1260 had NOAEL-based EEQs greater than 1 for birds and mammals, whereas the EEQs based on the LOAELs were less than 1.0. Therefore, whether birds and mammals will be affected is uncertain. Whether the Aroclor-1260 contamination extends across the taxiway is also unknown, so the size of habitat affected by elevated Aroclor-1260 concentrations cannot be determined. Probably only a few individual organisms would potentially be affected by Aroclor-1260, because of the relatively small size of the contaminated area.

Aquatic organisms are only exposed to surface water; therefore, chemical concentrations in groundwater were evaluated after the concentrations had been adjusted by a dilution factor to

account for groundwater discharge into surface water. Risks to aquatic organisms from exposure to groundwater are minimal because groundwater discharging to the surface water in Stansbury Creek or Frog Mortar Creek would be diluted many times at the groundwater/surface-water interface. Therefore, no chemicals were retained as COPC for risks to aquatic organisms.

Table 6-1

Exposure Parameters for the Terrestrial Wildlife Model
Greater Strawberry Point
Lockheed Martin, Martin State Airport
Middle River, Maryland

Species/Exposure Inputs	Conservative Inputs		Average Inputs	
	Values	Units	Values	Units
Bobwhite Quail				
Body Weight = BW	1.540E-01	kg	1.751E-01	kg

American Robin				
Body Weight = BW	7.73E-02	kg	8.04E-02	kg
Food Ingestion Rate = If	1.25E-02	kg/day	1.19E-02	kg/day
Soil Ingestion Rate - Is	2.046E-03	kg/day	7.601E-04	kg/day
Home Range = HR	Assume 100% on site		6.095E-01	acres
Short-Tailed Shrew				
Body Weight = BW	1.500E-02	kg	1.610E-02	kg
Food Ingestion Rate = If	1.600E-03	kg/day	1.433E-03	kg/day
Soil Ingestion Rate - Is	4.801E-05	kg/day	1.289E-05	kg/day
Home Range = HR	Assume 100% on site		9.699E-01	acres

Notes:
The exposure factors were derived as presented in Appendix P-2.

The soil ingestion rates were calculated by multiplying the food ingestion rates by the following incidental soil ingestion rates:

Receptor	Conservative	Average	Source
Bobwhite quail	13.90%	6.10%	1, 2
Meadow Vole	3.20%	1.20%	1
American Robin	16.40%	6.40%	1,3
Short-tailed Shrew	3%	0.90%	1

Shaded cells indicate that the EEQ exceeds 1 or no screening level is available.
EEQ is calculated by dividing the chemical concentration by its screening level presented in Appendix P-1.
1 - Average of detected concentrations only.
2 - Average of all analytical results including one-half of the detection limit for non-detects.
3 - State of Maryland Department of the Environment Cleanup Standards for Soil and Groundwater, June 2008. Appendix 2 - Attachment 2.
4 - Chemicals with EEQs for birds or mammals greater than 1.0 or important bioaccumulative chemicals without bird or mammal screening values are retained for food chain modeling.

Abbreviations:
COPC = Chemical of Potential Concern
EEQ = Ecological Effects Quotient
NA = Not available or not applicable

Rationale Codes for COPC Selection:
ASL = Above COPC Screening Level
BSL = Below COPC Screening Level
NSL = No Screening Level Available

Shaded cells indicate that the EEQ exceeds 1 or no screening level is available.
EEQ is calculated by dividing the chemical concentration by its surface water screening level presented in Appendix P-1.
1 - Average of detected concentrations only.
2 - Average of all analytical results including one-half of the detection limit for non-detects.
3 - No background data were available.

Abbreviations:
COPC = Chemical of Potential Concern
EEQ = Ecological Effects Quotient
NA = Not available or not applicable
J = estimated
µg/L = micrograms per liter

Rationale Codes for COPC Selection:
ASL = Above COPC Screening Level
BSL = Below COPC Screening Level
NSL = No Screening Level Available

Ecological Conceptual Site Model
Greater Strawberry Point, Lockheed Martin, Martin State Airport
Middle River, Maryland

Section 7
Summary

Additional Phase II environmental investigations were conducted in the area of Greater Strawberry Point (GSP) extending north from the current Martin State Airport (MSA) maintenance facility. The area of follow-up investigations, approximately 10 acres in size, includes two main study areas where previous environmental sampling indicates subsurface impacts near Recognized Environmental Conditions (RECs). The first area is a clearing between the Strawberry Point wooded area and Taxiway F, the former Propellant and Acetylene Storage Sheds, the former Furnace Building, the former Coupon Test Shed, Engine Test Building, and the former Block House (Recognized Environmental Conditions #8, #9, and #10). The follow-up investigation also included the former maintenance storage, critical test and radioisotope buildings and the former transformer pad, an approximate 2.5-acres area immediately south of Taxiway J (Recognized Environmental Condition #11).

The additional Phase II activities characterized chemical constituents and their concentrations in soil and groundwater using fixed-laboratory analyses to provide definitive chemical data for these environmental media. Chemical analytical results were screened against State of Maryland human health soil and groundwater standards. Assessment of ecological and human health risks was completed using soil and groundwater data collected for Greater Strawberry Point.

The following field investigations were completed from May–July 2011 in the Greater Strawberry Point area of Martin State Airport:

- an access agreement and associated permits for intrusive investigations were obtained from Lockheed Martin, Martin State Airport, and the Maryland Aviation Administration (MAA) (as applicable) to conduct the planned field activities
- soil borings were advanced at 40 locations to a depth of 25 feet each to collect soil lithologic information, to screen soil in the field for volatile organic compounds using a portable photo-ionization detector, and to collect soil samples for fixed-laboratory chemical analyses. Subsurface borings consisted of 10 soil borings in the area of Recognized Environmental Condition #8 and #9, 10 soil borings in Recognized

Environmental Condition #10, and 20 soil borings in Recognized Environmental Condition #11.

- soil samples from each test pit and soil boring were submitted for laboratory analysis, including volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), metals, total petroleum hydrocarbon (TPH)-diesel-range organics (DRO) and -gasoline-range organics (GRO)

- Twelve test pits were excavated in Recognized Environmental Conditions #9 and #10 to assess possibly buried materials/debris corresponding to several subsurface anomalies identified by a geophysical survey in 2010

- eight two-inch-diameter groundwater monitoring wells were installed in the areas of three Recognized Environmental Condition areas using a low-profile Mini-Roto-Sonic drill rig to approximately 32 feet below ground surface (bgs). Groundwater samples were collected from these eight new wells and eight existing temporary wells and submitted to a fixed laboratory for analysis of volatile organic compounds, semi-volatile organic compounds, polychlorinated biphenyls, total and dissolved metals, total petroleum hydrocarbon-diesel-range and -gasoline-range organics.

- the locations of new soil borings, test-pit excavations, and monitoring wells were surveyed by a Maryland-licensed professional surveyor

- static groundwater levels were measured at the eight newly installed wells in July 2011. These water levels were used to develop a local groundwater-elevation contour map.

- investigation-derived waste was collected, stored, characterized, and then disposed of at an off-site Lockheed Martin-approved treatment and disposal facility

- environmental sampling data were compared to Maryland human health soil and groundwater standards to identify exceedances

- a baseline human health risk assessment was performed using available soil and groundwater data to evaluate whether detected concentrations of chemicals in the GSP study area pose a significant threat to potential human receptors under current and/or future land uses

- a streamlined ecological risk assessment was conducted to determine whether adverse effects may occur in ecological receptors as a result of exposure to chemicals present in the environment at Greater Strawberry Point

The results of the Phase II activities are summarized below:

- The lithology encountered in the soil borings varies across the Recognized Environmental Condition. In the Recognized Environmental Condition #9, gray and brown silty sand and sandy silt with occasional clay lenses is encountered to a depth of 25 feet. The Recognized Environmental Condition #10 subsurface lithology is similar to Recognized

Environmental Condition #9, except for a more prominent clay layer that ranges between two and 6.5 feet thick, found primarily 10–20 feet below grade. The Recognized Environmental Condition #11 subsurface lithology varies slightly and ranges from an area in the north comprised of gray and brown silty sand and sandy silt overlying a thick clay layer (SB-120 and SB-121) to nearly all silty sand to a depth of 25 feet farther south (SB-122 and SB-123).

- Subsurface observations during the subject investigation indicate that the water table in the area ranges from approximately four to eight feet below grade. Groundwater elevations indicate that groundwater beneath the Greater Strawberry Point generally flows in a southerly direction toward Stansbury Creek. Groundwater mounding appears to occur near Recognized Environmental Condition #11, likely as a result of recharge from the storm-drain outlets in the western portion of the site.

- Debris and chemical analytical results for soils (elevated semi-volatile organic compounds, petroleum hydrocarbon, and metals concentrations) in test pit GSP-TP-5, are evidence of contamination resulting from the observed fill material and/or historical operations at Recognized Environmental Condition #10.

- Trace to low concentrations of volatile organic compounds were detected in one or more soil samples collected at Recognized Environmental Conditions #8/9, #10, and #11. Most of the detected volatile organic compounds are common laboratory contaminants, and considered artifacts of the laboratory analysis, since they were detected in the laboratory-blank samples. Trichloroethene was detected at low concentrations in one or more deep-soil samples at Recognized Environmental Conditions #8/9 and #11. All but one of the detected trichloroethene concentrations is less than Maryland residential and non-residential soil standards, and many were trace concentrations. The maximum detected concentration of trichloroethene is 2,900 µg/kg, in a soil sample collected at 22-25 feet in boring GSP-SB-92, at the northern border of Recognized Environmental Condition #8, near Recognized Environmental Condition #9. This sample was collected below the water table.

- Semivolatile organic compounds were detected in soil at several Recognized Environmental Condition areas. Benzo(a)pyrene was detected at concentrations exceeding residential criteria in one or more soil samples in Recognized Environmental Conditions #9, #10, and #11. Benzo(a)pyrene equivalents (BaPEq) were calculated for each of the soil samples (based on positive detects only) as a cumulative measure of the detected polycyclic aromatic-hydrocarbons (PAHs). The calculated benzo(a)pyrene equivalent in 11 surface soil samples at Recognized Environmental Conditions #9 and #10, and in 28 of the Recognized Environmental Condition #11 surface soil samples is greater than the conservative residential-screening level. However, most individual semivolatile organic compound and polycyclic aromatic-hydrocarbon concentrations are less than residential and non-residential standards.

  The highest concentrations of semivolatile organic compounds and greatest number of residential and non-residential exceedances were identified in subsurface soil samples in two borings at Recognized Environmental Condition #10 (GSP-SB-102-6-8 and GSP-SB-109-6-8) and two borings at Recognized Environmental Condition #11

(GSP-SB-120-18-20 and GSP-SB-121-6-8). Some other exceedances of residential and/or non-residential standards were also found involving isolated semivolatile organic compound detections in surface and subsurface soil samples from all four Recognized Environmental Condition areas.

- Polychlorinated biphenyls, primarily Aroclor-1260, were detected in 16 soil boring samples at concentrations ranging from 19–3,400 µg/kg. Most polychlorinated biphenyl detections were in shallow soil samples in the Recognized Environmental Condition #11 area. Aroclor 1260 concentrations in four shallow-soil samples at Recognized Environmental Condition #11 exceed both the Maryland residential and non-residential soil standards of 320 and 1,400 µg/kg, respectively.

- Concentrations of arsenic and vanadium in soil exceed their residential standards in most soil samples. Although arsenic and vanadium frequently exceed their risk-based standards, most detected concentrations of these two metals are similar to the Maryland Department of the Environment's (MDE's) anticipated typical concentrations (ATCs) or "regional background" concentrations for the eastern region of Maryland. Therefore, concentrations of these metals are generally consistent with local background and in most cases do not indicate a release at Greater Strawberry Point. One notable exception is in soil sample GSP-SB-111-6-8 (southeast of Recognized Environmental Condition #11), in which the detected concentrations of arsenic at 52 mg/kg and vanadium at 300 mg/kg are an order of magnitude greater than the anticipated typical concentrations of 3.6 mg/kg and 30 mg/kg, respectively. Total chromium concentrations in six soil samples representing three Recognized Environmental Condition areas exceed the residential standard. Two of these detected chromium concentrations (GSP-SB-91-8-10 at the southern Recognized Environmental Condition #9 boundary, and GSP-SB-109-6-8 in the northwestern Recognized Environmental Condition #10) are also greater than its anticipated typical concentration.

- Concentrations of diesel-range organics exceed residential standards in four shallow soil samples at Recognized Environmental Condition #10 and five soil samples at Recognized Environmental Condition #11, and exceed both the residential and non-residential standards in two surface soil samples from Recognized Environmental Condition #11.

- Four groundwater samples had trichloroethene concentrations exceeding the Maryland Department of the Environment groundwater standard/federal maximum contaminant level, and three were collected in Recognized Environmental Condition #11 area wells (GSP-MW-01, GSP-MW-04, and GSP-SB/WP-89). In Recognized Environmental Condition #11 groundwater samples, trichloroethene concentrations range from 1.3 µg/L (GSP-SB/WP-83) to 25 µg/L (GSP-SB/WP-89). Trichloroethene was detected at a maximum concentration of 450 µg/L in the groundwater sample collected from GSP-MW-07, in the southeast portion of Recognized Environmental Condition #9.

  Other volatile organic compounds detected in groundwater samples do not exceed standards and were typically common laboratory contaminants and artifacts of the laboratory analyses. Concentrations of arsenic, nickel, and vanadium exceed groundwater standards in one or more groundwater samples. Several exceedances of metals appear to be the result of high turbidity in groundwater samples, and were not present in the filtered

samples. Total petroleum hydrocarbon diesel-range organics were detected at concentrations exceeding the Maryland Department of the Environment standard in five groundwater samples, and one exceedance of the standard for total petroleum hydrocarbon gasoline-range organics was detected at GSP-MW-07.

- The human health risk assessment identified regulatorily unacceptable risks to human receptors assuming typical direct-contact exposure scenarios, given the identified levels of contaminants in surface soil, subsurface soil, and groundwater at Recognized Environmental Conditions #9, #10, and #11. Regulatorily unacceptable risks include ingestion, dermal contact, and inhalation of polycyclic aromatic-hydrocarbons (as benzo[a]pyrene equivalents) in surface and subsurface soils at Recognized Environmental Conditions #9, #10 and #11 by hypothetical child trespassers, lifelong recreational users, lifelong residents, as well as potential exposure to manganese in surface and subsurface soil by future construction workers. However, the risk assessment concludes that potential risks based on manganese in soils may be overestimated. (Analysis of manganese was not performed on the 2011 additional Phase II investigation soil samples.)

- Trichloroethene was retained as a contaminant of concern posing risk to hypothetical future residents based on potential direct contact, ingestion, and inhalation exposure to groundwater at Recognized Environmental Conditions #9, #10, and #11. In addition, trichloroethene in groundwater at these three Recognized Environmental Condition areas poses a potential vapor-intrusion risk for a hypothetical future resident or worker based on qualitative risk-analysis results. Trichloroethene was retained as a chemical of concern for migration to groundwater from soils at Recognized Environmental Conditions #9, #10, and #11.

- It should be noted that the human health risk estimates presented in this report were calculated in a conservative manner to assist risk managers tasked with making risk management decisions for Recognized Environmental Conditions #9, #10, and #11. These sites are currently within active airport area which is not used for residential or recreational purposes, and the potential for trespass is very limited. The groundwater resource is not used as a domestic water supply source. Thus, to a large extent, the risk estimates presented herein are for *hypothetical* receptor exposure should the land use scenario change.

- The streamlined ecological risk assessment identified potential risks to invertebrates and plants based on exposure to manganese in surface soil at Recognized Environmental Conditions #9 and #10. Potential risks to birds and mammals were also identified, based on exposure to Aroclor-1260 in surface soil at Recognized Environmental Condition #11.

The collective findings of the Greater Strawberry Point investigations to date support the following future site activities. Additional delineation sampling may be required to help define the extent of:

- total petroleum hydrocarbons diesel-range organics exceedances in surface and subsurface soils in the western portion of Recognized Environmental Condition #10;

- Arsenic, vanadium, and/or chromium exceedances in surface and subsurface soils in the vicinity of boring GSP-SB-108, located in the western portion of Recognized Environmental Condition #10, and in subsurface soils at GSP-SB-91, at the eastern limits of Recognized Environmental Condition #9

- total petroleum hydrocarbon diesel-range organics and polychlorinated biphenyl exceedances in surface soils along the western extent of the Recognized Environmental Condition #11 investigation area (near borings GSP-SB-118 through GSP-SB-122)

- polychlorinated biphenyl and/or total petroleum hydrocarbon diesel-range organics exceedances in subsurface soil samples in borings GSP-SB-119 and GSP-SB-121 near the western extent of Recognized Environmental Condition #11

- Polycyclic aromatic-hydrocarbons (and related benzo[a]pyrene equivalents), particularly in subsurface soils around borings GSP-SB-102 and GSP-SB-110 at Recognized Environmental Condition #10 and borings GSP-SB-120 and GSP-SB-121 at Recognized Environmental Condition #11, and in surface soils at GSP-SB-124 at Recognized Environmental Condition #11.

Proposed additional investigative work includes membrane-interface-probe characterization and soil sampling at up to 25 locations to assess sources of trichloroethene in groundwater near well GSP-MW-07 and in the area of Recognized Environmental Condition #11. Modeling using the Johnson and Ettinger model should be considered to assess potential exposure to workers posed by potential vapor-intrusion in occupied buildings at Recognized Environmental Conditions #9, #10 and #11. This effort would include future soil-gas sampling at 25 locations near the maintenance building, and indoor-air sampling at 10 locations. It is recommended that up to 12 additional permanent groundwater monitoring wells be installed down to 30 feet below grade to provide for future sampling of shallow groundwater.

At least three wells should be installed in the area south (downgradient) of GSP-MW-07 (and into Recognized Environmental Condition #8), to assess the extent of trichloroethene in area groundwater. At least five wells should be installed near the maintenance building to provide for future groundwater monitoring of this area. Other wells (approximately four) should be installed in the downgradient portion of Recognized Environmental Condition #11, to help identify the downgradient extent of trichloroethene in groundwater. Modeling should be considered using existing soil and groundwater data to evaluate the migration, receptors, and fate and transport of contaminants at Greater Strawberry Point through the completion of a feasibility study.

APPENDIX A—DIG PERMITS AND UTILITY-CLEARANCE REPORTS

Maryland Aviation Administration

Martin O'Malley
Governor

Anthony G. Brown
Lt. Governor

Beverley K. Swaim-Staley
Secretary

Paul J. Wiedefeld, A.A.E.
Executive Director

April 20, 2011

VIA FACSIMILE: 301-528-3000
Mr. Anthony Apanavage
Tetra Tech
20251 Century Boulevard, Suite 200
Germantown MD 20874

Mr. Apanavage:

SUBJECT: Airport Zoning Permit No.'s 11-075 A, B, and C (Borings and Well Installations)
Building Permit No.'s 11-019, 11-020, and 11-021

Maryland Aviation Administration's (MAA) Office of Planning and Environmental Services (OPES) has received and reviewed the subject applications and determined that the proposed project lies within the Martin State Airport (MTN) Airport Zoning District. To ensure the safety of the traveling public, Code of Maryland Regulations (COMAR) authorizes MAA to review each project proposed within the Airport Zoning District, which is defined as the area within 3.3 miles of a fixed point on MTN.

The MAA has reviewed the applications to identify any hazards to the airspace surrounding MTN. Our analysis has revealed that some of the proposed activity may potentially create hazards to air navigation. However, it is possible to mitigate such hazards by conducting activity in these areas only when the adjacent runway, taxiway/taxilane is closed. Additionally, several other sites are positioned such that aircraft activity on adjacent taxiways and/or the runway can occur simultaneous to construction activity only when the appropriate safe guards are in effect. Before proceeding with any construction activity it is essential that the requirements outlined below and further in the attached matrices regarding lighting/marking and all other safety measures are in place as required.

The attached matrix labeled "Runway or Taxiway Closure Required" details the locations where taxiway/taxilane or runway closures are necessary and specifies pre-construction and operating requirements.

The attached matrix labeled "Runway 15 Localizer Impacts" details the locations where activity will be performed between Runway 15-33 and Taxiway T, and also within the Runway 15 Localizer Critical Area. Activity in this area can proceed simultaneous to activity on the adjacent runway and taxiway, but can not be pursued until the Runway 15 Localizer is protected by MTN Operations and pre-construction and operating requirements have been performed.

Finally, the attached matrix labeled "Restricted Activity" details the locations where activity will be performed between Runway 15-33 and a taxiway, but not within the Localizer Critical Area. Activity in this area can proceed simultaneous to activity on the adjacent runway and taxiway, but can not be pursued until pre-construction and operating requirements have been performed.

Airport Zoning Application No.'s 11-075 A, B, and C are hereby approved for a maximum equipment height of 44 feet Above Mean Sea Level (AMSL)/35 feet Above Ground Level contingent on satisfying the conditions established in this letter and attachments. In no way should the requirements specified in this letter or the attachments be construed as all encompassing. Before initiating activity in the vicinity of any sites at MTN, you must contact MTN Operations at 410-682-8831 for official Notice-To-Proceed and final direction.

Sincerely,

Shawn P. Ames, Manager
Division of Airport Facilities Planning

Enclosures

cc: Mr. Charles Baublitz, Chief Airport Operations, MTN
Mr. Alfred Pollard, A.A.E, Director, MTN
Ms. Karen Riddle, Permit Coordinator, Tenant Improvements, MAA

Mr. Anthony Apanavage
Tetra Tech
20251 Century Blvd Suite 200
Germantown, Maryland 20874

Dear Mr. Apanavage:

SUBJECT: Building Permit BP-11-019 Environmental Investigation at Martin State Airport Greater Strawberry Point

Please find enclosed the approved Permit for the above referenced project. Permit approval is subject to compliance with provisions and stipulations contained in the Permits Information Guide (September 2007 Edition) and Tenant Directive 007.01. The issuance or granting of this permit shall not be construed to be an approval of any violation of other Maryland Aviation Administration (MAA) or Code of Maryland (COMAR) regulations. MAA reserves the right to suspend or revoke the permit whenever it is deemed to be issued on the basis of incorrect, inaccurate or incomplete information provided by the applicant.

Please see the attached contact list of MAA departments and offices that need to be contacted prior to the start of work. Also, please refer to the Permits Information Guide to see if any other permit or authorization is required. The approved Permit, Permit Plan Set and Permit Comments shall be kept at the project location until the completion of the project. Revisions to design shall be submitted to and approved by MAA Division of Documents & Permits prior to construction. **As-Built drawings are to be submitted no later than 45 days from Final Inspection acceptance.**

This permit shall become invalid unless the work on the site authorized by this permit is commenced within 180 days after issuance, or if the work is suspended or abandoned for a period of 180 days after the work is commenced. The issuance of this permit shall not relieve the applicant from his/her responsibility to ensure proper design and construction of this project.

Sincerely,

Syed Shariq R.A., Manager
Division of Documents & Permits

Approval	Permit No. BP-11-019
Syed Shariq, R.A. Manager, Division of Documents & Permits	Date Issued: 4-27-11

THIS PERMIT IS ISSUED BY MARYLAND AVIATION ADMINISTRATION AS AUTHORIZATION TO PERFORM APPROVED CONSTRUCTION ACTIVITIES AS DESCRIBED AND SHOWN ON APPROVED PERMIT PLANS AND SPECIFICATIONS

Post in a Conspicuous Place at Job Site

Building Permit No. BP-11-019 is ***approved as noted*** and subject to compliance with the applicable codes, MAA Design Standards and the follow comments:

- **Work on or near runway and /or taxiways shall be accomplished during nighttime (10:00pm to 6:00 am). Coordinate digging/construction activity with Charles Baublitz, Tel. 410-682-8805.**
- **Test pits exceeding four feet in depth shall either have "shoulders" cut into the banks or a trench box shall be used.**

GENERAL COMMENTS

1. Applicable Codes & Regulations as per Tenant Directive 007.1 apply.

2. Display MAA Permit on site at all times

3. Secure all tools and equipment in public/sterile areas and ensure that all doors are locked when no one is present in the construction area. No tools are to be left unattended. Follow proper escort procedures in the SIDA.

4. All loose debris/trash, on or about AOA, shall be deposited in an acceptable, covered trash receptacle. No debris/trash shall be left about on roof, spaces open to the AOA, conveyance, or near open trash receptacles at any time.

5. Firestop penetrations through fire rated assemblies and seal all unused/abandoned openings using appropriate UL-listed firestopping systems.

6. Sleeves:
   - Sleeves shall be installed for cable and raceway penetrations of concrete slabs, masonry and fire rated gypsum walls and other floor and wall assemblies.
   - Sleeves will be installed during erection of concrete and masonry walls.
   - Sleeves shall be installed in concrete slabs supported by pan decking to ensure full sealing of the uneven lower surface around the pan.
   - New concrete slabs are acceptable to be poured with the concrete surrounding the new conduit without the use of sleeves.

7. Provide support to structural member for any mechanical, electrical or other building elements not scheduled for removal but attached to items being demolished.

8. Core drilling, concrete floor cutting or other removal methods (on-grade, elevated, and post tensioned) shall be preceded by NDT to show that no embedded conduits or structural reinforcing will be disturbed in the proposed locations. The MAA Design Standard DST 2007-01 Core Drilling of Concrete Floors shall be used as reference.

9. Electrical:
   - Electrical, communication, security or fire safety wiring/systems shall not be interrupted without notification and coordination with authority having jurisdiction and written approval by said authority.
   - MC/FMC ¾ inch minimum size, 6 foot maximum length; except as allowed to fish existing walls per MAA Design Standards. Cont'
   - Raceway size shall be ¾" minimum.
   - All conduit fittings shall be steel.
   - All wire/cable shall be plenum rated.
   - Only brushed stainless steel device covers allowed.
   - Exothermic weld required for electrical grounding to building steel per MAA-DST.
   - Install expansion joints at points required.
10. Mechanical/Plumbing:
   - Roof mounted equipment issues:
     -Gas pipe exposure on the roof shall be minimized.
     -Roof mounted equipment condensate drains shall be routed to the nearest roof drain.
     -Condensate drains shall not rest directly on the roof.
     -Existing roof warranties shall be maintained.

- High pressure stainless steel couplings shall be used on all sanitary waste and vent piping.

11. Hot Work & Welding:
    - Open flame welding and cutting shall not be allowed without burning permit as issued.
    - During flame welding and flame/mechanical cutting operations install protective weld screens and non-flammable fire protection blankets.

Date of Meeting:	
Date of Release:	

GREATER STRAWBERRY POINT – 2011 SCOPE OF WORK

1. Advance 40 soil borings
2. Excavate 12 test pits
3. Install 8 groundwater monitoring wells

Soil Borings

Soil and groundwater samples will be collected from 40 proposed soil borings using DPT. The DPT locations will include 10 soil borings in REC #9, 10 soil borings in REC#10, and 20 soil borings in REC #11. Figure 1 shows the locations of the soil borings to be advanced. These locations are currently provisional and may be relocated based on discussions with MAA personnel, conditions stipulated in the permit, or field conditions.

Prior to any subsurface drilling, if the soil boring locations are located in concrete, they will be cored to allow access to the subsurface soils for the DPT soil-sampling. The soil borings will be advanced by a Maryland-licensed driller in the targeted areas using DPT to approximately 25 feet below ground surface (bgs). Continuous soil samples (DPT Macrocores) will be collected in each boring using a 1.5-inch diameter, 4-foot long stainless steel macrocore sampling fitted with a disposable acetate liner. The probe sampler will be advanced in 4 or 5 foot increments and the retrieved soil samples will be collected for soil screening, including lithologic characterization and visual observations. Soil samples will be screened with a photoionization detector (PID) using a consistent headspace screening methodology (e.g., foil sealed jar or zip top bag technique). Two or three soil samples from each of the proposed 40 soil borings will be collected for laboratory analyses. Depths of the subsurface soil samples (i.e., those at depths greater than 2 feet) may vary depending on indications of contamination such as elevated PID readings, stained soil, or odor. Lithologic logging will be performed by a qualified Tetra Tech field geologist.

Locations where penetrating existing concrete is required for sampling will be surface completed and restored with low shrinkage concrete upon completion of backfilling. Backfilling will consist of using granular bentonite up to a depth of approximately one foot bgs that will be hydrated to

provide a seal. The remainder of the borehole will be finished smooth and flush with the existing grade with patch material (concrete).

Test Pits

Twelve test pits will be excavated to evaluate the presence of buried materials/debris at geophysical anomalies identified by a survey conducted at RECs #9 and #10 in 2010. Figure 1 presents the locations of the test pits to be excavated.

A rubber-tired backhoe will be mobilized to excavate the test pits. Test pits will be excavated in areas of anomalies to investigate the nature of the metallic responses, with emphasis on determining the presence of buried remains of remnant structures, tanks and metallic debris. Test pits will be excavated to the water table or until the bottom of any debris is encountered. If debris is found, a soil sample will be collected from the zone immediately below the material. Soil samples will also be collected from soil with observed staining or odors. Soil type and anthropogenic material encountered in the test pits will described, photographed, and a test pit log will be completed. Test pits are estimated to be approximately 30 feet long and no more than 12 feet deep. The actual pit dimensions will be dependent on observations in the field.

At all times during the excavating activities, the Tetra Tech field geologist accompanied by a Field Operations Leader will be present to visually monitor the excavation. The geologist will monitor for the presence of waste chemicals, liquids, and metallic objects and the Field Operations Leader will focus on field communications, health and safety monitoring and provide field directions to ensure safe operation of the equipment and personnel during excavation. At all times during test pit excavation a Tetra Tech unexploded ordnance (UXO) technician will be present to visually monitor the excavation. The geologist will monitor for the presence of waste chemicals, liquids, and metallic objects and the UXO technician will focus on visual observation of UXO during excavation. If UXO is discovered, field work will be terminated and the area will be marked and secured. MAA will be notified immediately. No further work will be performed in the UXO discovered locations. While there is no direct evidence that UXO was disposed at the site, test pit excavations completed in 1999 uncovered one 100 lb., two 1,000 lb., and one 2,000 lb. inactive (dummy) bombs. Therefore, UXO oversight is being performed as a precautionary step. Where debris is found and in areas where liquids containers (drums, buckets, etc,) or soil staining is observed, soil samples will be collected.

Wells

The monitoring wells will be installed at eight locations using a low-profile mini-sonic rig to a maximum depth of 32 feet below grade by a licensed Maryland driller to characterize groundwater conditions in the areas of study. The drilling will be advanced using a rotasonic-drilling method. The rotasonic method involves having the four-inch by six-inch drill rod/over-ride-casing set-up (with temporary casing) to install the well to total depth. Figure 1 shows the locations of the wells.

In paved or high traffic areas such as taxiways, roads, lots, etc., the well casing will be cut below grade and protected by installing a steel, flush mounted well cover and a water-tight, expandable, sanitary seal at each well head. At these locations, concrete will be installed above the grout in the annular space between the borehole and outer well casing up to approximately 6-inches below grade to provide a surface seal for the well.

RE: Geophysical Survey
Utility/Structure Clearance for 60 Proposed Boring Locations
Martin State Airport Greater Strawberry Point Area
Middle River, MD
Enviroscan Project Number 051102

Dear Mr. Murali:

Pursuant to the specifications of our proposal, dated May 1, 2011, Enviroscan, Inc. conducted a multi-technique geophysical survey at the above-referenced site from May 20 to May 26, 2011. The purpose of the survey was to perform utility clearance for 60 proposed soil borings.

Methods

The utility survey was completed using standard and/or routinely accepted practices of the geophysical industry and equipment representing the best available technology, including:

- a Radiodetection RD8000 Multi-Frequency pipe and cable tracer;
- a Radiodetection C.A.T. and Genny pipe and cable locator/tracer;
- a Fisher TW-6 electromagnetic (EM) pipe and cable locator/tracer;
- a GSSI SIR-2000 ground penetrating radar (GPR) system.

The principles of these techniques are detailed below.

RD8000

Utility tracing was conducted using a Radiodetection RD8000 digital cable and pipe tracer. The transmitter can be directly coupled to exposed portions of a metallic pipe, cable, or wire or indirectly (inductively) to a subsurface metallic utility of known location/orientation. The transmitter remains stationary and energizes the metallic utility at a frequency selected by the operator (512 Hz, 8 kHz, 33 kHz, or 65 kHz), which is received at the ground surface by the digital locator. When the transmitter is directly coupled to the metallic utility, the digital receiver can also calculate the depth of the utility to an accuracy of ±10% of the actual depth of the utility. Please note the close proximity to bends in the traced line or poor signal strength can result in erroneous depth estimations.

C.A.T. and Genny

The survey areas were also scanned with a Radiodetection C.A.T. and Genny pipe and cable locator and tracer. In Power mode, the C.A.T. detects the 50 to 60 Hertz (Hz) electromagnetic field generated by live power cables and other metallic utilities to which a live line is grounded. In Radio mode, the C.A.T. detects buried conductors (cables or metallic pipes) as they conduct and re-transmit commercial broadcast radio energy. In Genny mode, the C.A.T. detects signal generated by the Genny transmitter. The Genny transmitter can be coupled directly (conductively) to exposed portions of a metallic pipe, cable, or wire or inductively to a subsurface metallic utility with known location and orientation.

TW-6

In order to detect unknown utilities, Enviroscan employed a Fisher TW-6 pipe and cable locator and tracer. In pipe and cable search mode, the TW-6 is essentially a deep-sensing metal detector that detects any highly electrically conductive materials (e.g. metals) by creating an electromagnetic field with a transmitting coil. A receiving coil at a fixed separation from the transmitter measures the field strength. As the instrument is swept along the ground surface, subsurface metallic bodies distort the transmitted field. The change in field strength/orientation is sensed by the receiver, setting off an audible alarm and/or causing deflection of an analog meter. The TW-6 can nominally detect a 2-inch metal pipe to a depth of 8 feet and a 10-inch metal pipe to a depth of 14 feet.

In pipe and cable tracing mode, the TW-6 transmitter can be coupled directly (conductively) to exposed portions of a metallic pipe, cable, or wire or inductively to a subsurface metallic utility with known location and orientation. The transmitter remains stationary and energizes or excites the metallic utility to be traced with an 81.92-kilohertz signal that can be traced at the ground surface using the mobile TW-6 receiver wand or probe.

GPR

GPR systems produce cross-sectional images of subsurface features and layers by continuously emitting pulses of radar-frequency energy from a scanning antenna as it is towed along a survey profile. The radar pulses are reflected by interfaces between materials with differing dielectric properties. The reflections return to the antenna and are displayed on a video monitor as a continuous cross section in real time. Since the electrical properties of metal are distinctly different from soil and backfill materials, metallic pipes and other structures commonly produce dramatic and characteristic reflections. Fiberglass, plastic, concrete, and terra-cotta pipes and structures also produce recognizable, but less dramatic reflections. Scanning was performed using a GSSI SIR-2000 GPR controller with an internal hard drive and a color display, and both a high-frequency, high-resolution 500 megaHertz (MHz) antenna or transducer, and a lower frequency deep-penetrating 200 MHz transducer.

Results Summary

The utility clearance survey results are depicted in Figures 1 through 4. Several boring locations were moved (less than 20 feet) to avoid obstructions. These new locations are noted in Table 1. The proposed coordinates of boring locations that were moved appear in red. Please note that the new coordinates of boring locations moved during geoprobing (by others) to avoid marked utilities or obstructions to drilling do not appear on Table 1.

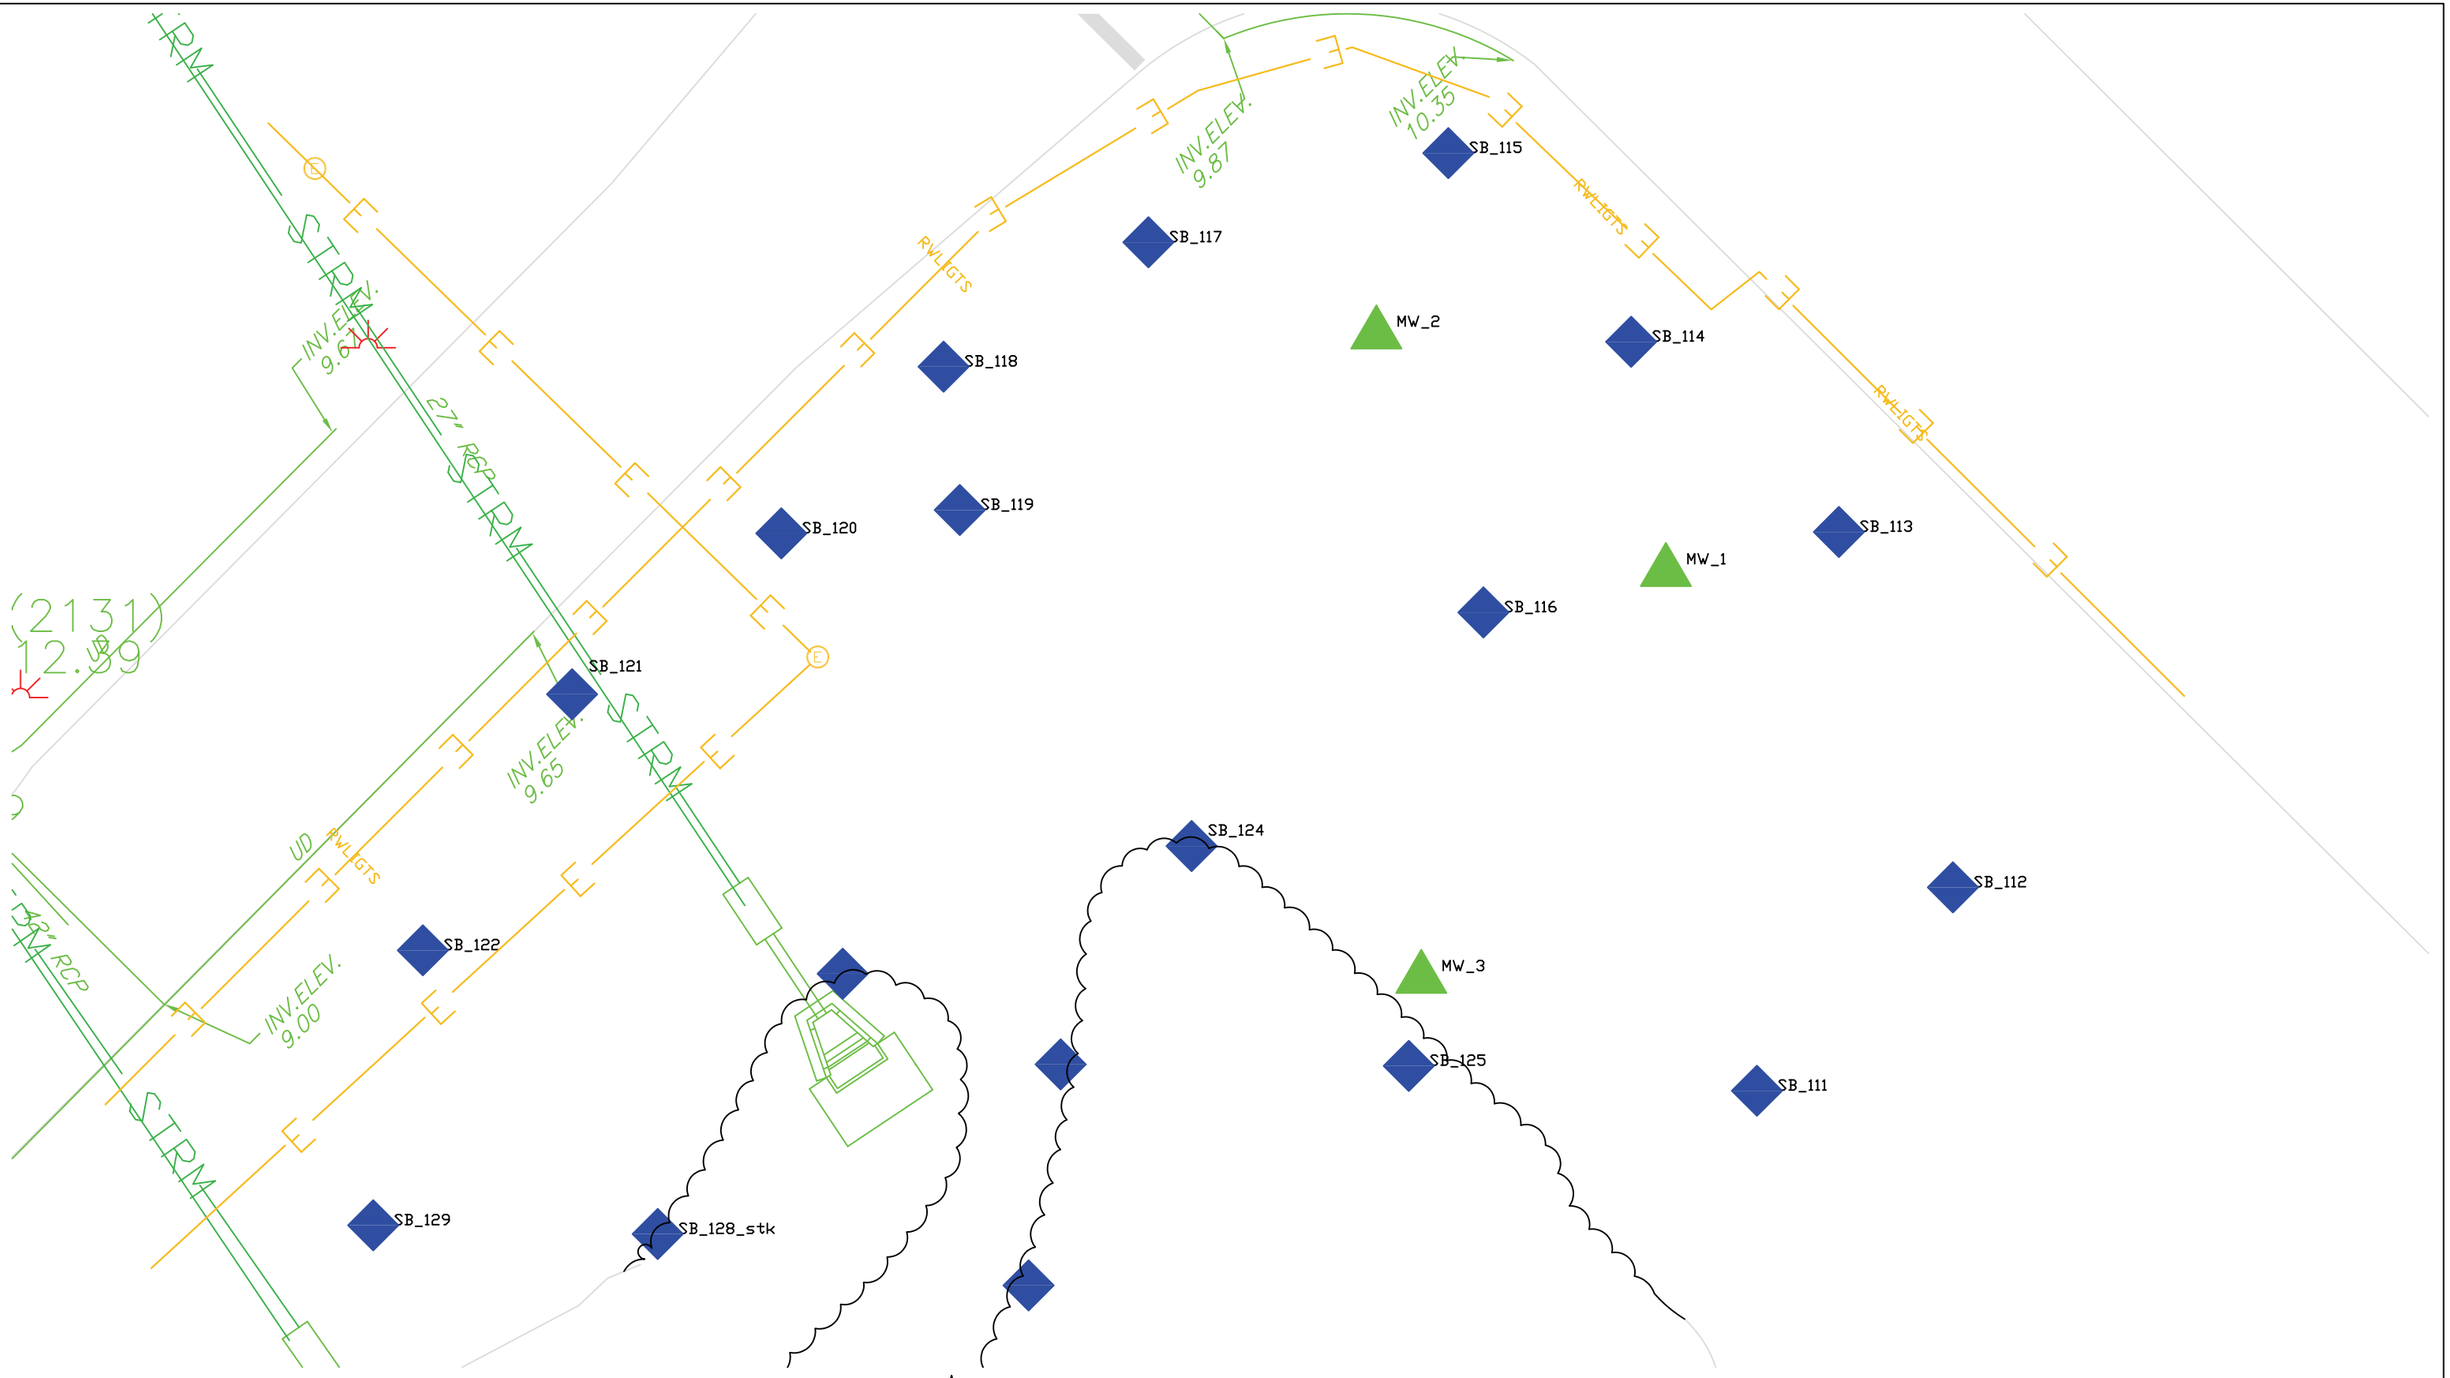
Limitations

The above-referenced geophysical survey was completed using standard and/or routinely accepted practices of the geophysical industry and equipment representing the best available technology. Enviroscan does not accept responsibility for survey limitations due to inherent technological limitations or unforeseen site-specific conditions. However, we make every effort to identify and notify the client of such limitations or conditions. In particular, please note the following specific limitations and recommendations:

- Enviroscan's field markings should be considered accurate to within approximately +/-18 inches for single lines. In contrast, since electromagnetic tracing of duct banks provides only a centerline, the bank itself may extend for 2 to 3 feet beyond the marked trace.

- The completion of this survey does not relieve any party of applicable legal obligations to notify the appropriate One-Call center prior to digging or drilling.

As always, we appreciate this opportunity to have worked with you. If you have any questions, please do not hesitate to contact me.



Sincerely,
Enviroscan, Inc.

William E. Steinhart III, M.Sc., P.G.
Principal Geophysicist

APPENDIX C—TEST PIT OBSERVATIONS AND PHOTOGRAPHS

Legend:
Dimensions: length x depth
ft. bgs: feet below ground surface
DTW: depth to water
NA: not recorded/not reached

Pit#: GSP-TP-1

Photo #1: TP-1 (debris)

Photo #2: TP-1 (lithology)

Photo #3: TP-1 (overview)

DTW: 12 feet below grade

Dimensions: 30x12.5 feet.

Description: Brown, course grained SILTY SAND with high organic from the ground surface to two and a half feet below grade where a fine grained, gray, yellow-brown, and brown fine grained moist SILTY SAND occurs down to seven feet below grade. From this depth to the bottom of the test pit at 12.5 feet below grade, the lithology consists of a light gray and brown fine grained and moist SANDY SILT/SILTY SAND.

Photo #1: Cinder block found at 9 feet below grade
Photo #2: Test pit lithology

Photo #3: Test pit overview

Pit#: GSP-TP-2

Photo #4: TP-2 (debris)

Photo #5: TP-2 (lithology)

DTW: NA

Dimensions: 30x12 feet.
Description: Dark brown, medium grained, moist SANDY SILT with high organic content from the ground surface to one foot below grade where lithology changes to tan compact, medium grained, moist SILTY SAND down to six feet below grade (color changes to orange-brown and yellow-brown at four feet, and to light gray at five feet. From six feet to the bottom of the test pit at 12 feet below grade, the lithology consists of dark gray, stiff, slightly moist, low plasticity CLAY with trace SILT.

Photo #4: Metal debris found near within 2 feet of the surface
Photo #5: Test-pit lithology

Pit#: GSP-TP-3

Photo #6: TP-3 (concrete slab)

Photo #7: TP-3 (overview)

DTW: 9 feet below grade

Dimensions: 30x10 feet.
Description: Brown, yellow-brown, course grained, loose, dry, SILTY SAND with

gravel is found from the ground surface to four and a half feet below grade where lithology changes to light gray, compact, medium grained, moist CLAYEY SILTY SAND down to the bottom of the test pit at 10 feet.

Photo #6: Approximately 4 foot thick concrete slab found from 1 to 5 feet below grade.
Photo #7: Test Pit overview

Pit#: GSP-TP-4

Photo #8: TP-4 (concrete slab)

Photo #9: TP-4 (debris)

DTW: NA

Dimensions: 30x12 feet.
Description: Dark brown, course grained, loose, dry, GRAVELLY SILTY SAND is found from the surface to three feet below grade with some asphalt at .5 feet. From three to five and a half feet below grade, yellow-brown, medium grained, loose, moist, SILTY SAND is encountered followed by light gray, medium grained, compact, moist, CLAYEY SILTY SAND to the bottom of the test pit at 12 feet.

Photo #8: Approximately 4 foot thick concrete slab found from the surface to 4 feet below grade.
Photo #9: Tires found about 2 feet below grade (a traffic cone was also found in the test pit at about 4 feet below grade)

Pit#: GSP-TP-5 Photograph #s: 10 and 11

Photo #10: TP-5 (debris)

Photo #11: TP-5 (overview)

DTW: NA

Dimensions: 30x12 feet.

Description: Brown, coarse grained, loose, dry, SILTY SAND is encountered from the ground surface to 12 feet below grade with some orange-brown CLAY lenses at one half and five feet. At 12 feet below grade, black staining with an odor was found with photoionization detector (PID) readings from 10.7 to 28.4.

Photo #10: Concrete and metal debris found abundantly throughout the test pit.
Photo #11: Test pit overview

Pit#: GSP-TP-6

Photo #12: TP-6 (concrete)

Photo #13: TP-6 (debris)

Photo #14: TP-6 (lithology)

Photo #15: TP-6 (overview)

DTW: NA

Dimensions: 30x11 feet.
Description: Brown, yellow-brown, loose, dry, SANDY SILT with gravel, rocks and debris from the surface to three feet below grade. From three to seven feet the lithology consists fine grained, moist SILTY SAND which is black and loose down to five feet and yellow-brown and compact down to seven feet below grade. The bottom depths of the test pit consisted of light gray, fine grained, compact, moist CLAYEY SILTY SAND from seven to 11 feet below grade.

Photo #14: Test pit lithology
Photo #15: Test pit overview

Pit#: GSP-TP-7

Photo #16: TP-7 (lithology)

Photo #17: TP-7 (overview)

DTW: NA

Dimensions: 30x10 feet.
Description: Brown, course grained, loose, dry SANDY SILT with organics was found from the ground surface to about one foot below grade where lithology changes to yellow-brown, tan, loose, moist SANDY SILT with rocks down to three feet below grade. Below three feet below grade the lithology consisted of yellow-brown, light gray, compact, moist, coarse grained CLAYEY SILTY SAND down to seven feet, followed by light gray, stiff, no plasticity, slightly moist SILTY CLAY to the bottom of the test pit.

Photo #16: Test pit lithology.
Photo #17: Test pit overview

Pit#: GSP-TP-8

Photo #18: TP-8 (angle iron and pipe)

Photo #19: TP-8 (hydraulic cylinder)

Photo #20: TP-8 (overview)

DTW: 7.5 feet below grade

Dimensions: 12x2x10 feet.
Description: Brown, medium grained, loose, dry, SANDY SILT organics were found from the surface to two and a half feet below grade, followed by yellow-brown, fine grained, loose, moist, SAND with some SILT down to five and a half feet. From five and a half feet to the bottom of the test pit at seven and a half feet, the lithology consisted of light gray, fine grained, loose, moist, SAND with some SILT.

Photo #18: Pipes and angle iron found near the surface
Photo #19: Hydraulic cylinder found about one foot below grade
Photo #20: Test pit overview

Pit#: GSP-TP-9

Photo #21: TP-9 (overview)

DTW: 9 feet below grade

Dimensions: 17x10 feet.

Description: Brown, loose, dry, course grained SILTY SAND with some organics and gravel were found from the surface to one foot below grade, followed by brown, yellow-brown, medium grained, compact, moist, SILTY SAND down to eight feet. From 8 feet to the bottom of the test pit at 10 feet below grade, the lithology consisted of light gray, medium grained, loose, moist, SILTY SAND.

Photo #21: Test pit overview

Pit#: GSP-TP-10

Photo #22: TP-10 (lithology)

Photo #23: TP-10 (overview)

DTW: 12 feet below grade

Dimensions: 17x12.5 feet.

Description: Brown, loose, coarse grained, dry SANDY SILT with organics was found

from the surface to three feet below grade. From three feet below grade to the bottom of the test pit at 12.5 feet, the lithology consisted of slightly compact, moist, medium grained SILTY SAND which was yellow-brown down to four feet, light gray down to six feet, and light gray and yellow-brown down to 12.5 feet.

Photo #22: Test pit lithology
Photo #23: Test pit overview

Pit#: GSP-TP-11

Photo #24: TP-11 (pipe)

Photo #25: TP-11 (overview)

DTW: 8 feet below grade

Dimensions: 30x8 feet.
Description: Loose, moist, fine grained SILTY SAND was found from the surface to the bottom of the test pit at eight feet below grade which was brown down to a foot, yellow-brown down to five feet, and light gray to eight feet. The lithology becomes compact at eight feet below grade.
Photo #4: Pipe found at about two feet below grade
Photo #5: Test pit overview

DTW: 8 feet below grade

Pit #: GSP-TP-12 (No Photos)

Dimensions: 30x8 feet.
Description: Brown, loose, dry, coarse grained SILTY SAND was found from the surface to one foot below grade followed by yellow-brown, medium grained, compact, moist CLAYEY SILTY SAND down to five and a half feet. From five and a half down to the bottom of the test pit at nine feet below grade, the lithology consisted of light gray, stiff, slightly moist, fine grained SILTY SANDY CLAY with some red-brown coloration from 8 to 9 feet.

SAMPLING DATA:

Date: 6/23/11	Color	pH	S.C.	Temp.	Turbidity	DO	Salinity	Other
Time: 10:40	(Visual)	(S.U.)	(mS/cm)	(°C)	(NTU)	(mg/l)	(%)	ORP
Method: Low Flow	—	4.59	0.259	17.52	~~129~~ 129	0.41	—	188

PURGE DATA:

Date: 6/23/11	Volume	pH	S.C.	Temp.	Turbidity	DO	Salinity	Other
Method: Low Flow								
Monitor Reading (ppm):								
Well Casing Diameter & Material Type: 1" PVC		See Low Flow Purge Data Sheet						
Total Well Depth (TD): 19.0'								
Static Water Level (WL): 7.71'								
One Casing Volume(gal/L):								
Start Purge (hrs): 09:05								
End Purge (hrs): 9:55								
Total Purge Time (min): 50 min.								
Total Vol. Purged (gal/L): 3 gal								

SAMPLE COLLECTION INFORMATION:

Analysis	Preservative	Container Requirements	Collected
VOCs	HCl	3-40mL vials	
Total Metals	HNO_3	1-500mL plastic	
Diss Metals	HNO_3	1-500mL plastic	
SVOCs + 1,4-Dioxane	—	2-1L Ambers	
TPH GRO	HCl	2-40mL vials	
TPH-DRO	H_2SO_4	2-1L Ambers	
perchlorate	—	1-250mL plastic	
Hex chrom.	—	1-250mL plastic	

OBSERVATIONS / NOTES:

Hex chrom collected at 13:25

Circle if Applicable:

1 Based on an October 2010 survey of all Dump Road Area wells
2 Well has been sealed and abandoned in accordance with state regulations and is no longer in use
NA - Not available or not measured
S - Upper surficial aquifer
I - Intermediate surficial aquifer
D - Lower surficial aquifer
DD - Deep confined aquifer or below the lower surficial aquifer
NAVD88 = North American Vertical Datum of 1988.
NAD83 - North American Datum of 1983

Table 4-3

Groundwater Levels and Elevations
Lockheed Martin Martin State Airport, Middle River, Maryland

1 Based on an October 2010 survey of all Dump Road Area wells
2 Well has been sealed and abandoned in accordance with state regulations and is no longer in use
NA - Not available or not measured
S - Upper surficial aquifer
I - Intermediate surficial aquifer
D - Lower surficial aquifer
DD - Deep confined aquifer or below the lower surficial aquifer
NAVD88 = North American Vertical Datum of 1988.
NAD83 - North American Datum of 1983

Table 4-3

Groundwater Levels and Elevations
Lockheed Martin Martin State Airport, Middle River, Maryland

1 Based on an October 2010 survey of all Dump Road Area wells
2 Well has been sealed and abandoned in accordance with state regulations and is no longer in use
NA - Not available or not measured
S - Upper surficial aquifer
I - Intermediate surficial aquifer
D - Lower surficial aquifer
DD - Deep confined aquifer or below the lower surficial aquifer
NAVD88 = North American Vertical Datum of 1988.
NAD83 - North American Datum of 1983

Table 4-3

Groundwater Levels and Elevations
Lockheed Martin Martin State Airport, Middle River, Maryland

1 Based on an October 2010 survey of all Dump Road Area wells
2 Well has been sealed and abandoned in accordance with state regulations and is no longer in use
NA - Not available or not measured
S - Upper surficial aquifer
I - Intermediate surficial aquifer
D - Lower surficial aquifer
DD - Deep confined aquifer or below the lower surficial aquifer
NAVD88 = North American Vertical Datum of 1988.
NAD83 - North American Datum of 1983

Table 4-3

Groundwater Levels and Elevations
Lockheed Martin Martin State Airport, Middle River, Maryland

1 Based on an October 2010 survey of all Dump Road Area wells
2 Well has been sealed and abandoned in accordance with state regulations and is no longer in use
NA - Not available or not measured
S - Upper surficial aquifer
I - Intermediate surficial aquifer
D - Lower surficial aquifer
DD - Deep confined aquifer or below the lower surficial aquifer
NAVD88 = North American Vertical Datum of 1988.
NAD83 - North American Datum of 1983

1 Based on an October 2010 survey of all Dump Road Area wells
2 Well has been sealed and abandoned in accordance with state regulations and is no longer in use
NA - Not available or not measured
S - Upper surficial aquifer
I - Intermediate surficial aquifer
D - Lower surficial aquifer
DD - Deep confined aquifer or below the lower surficial aquifer
NAVD88 = North American Vertical Datum of 1988.
NAD83 - North American Datum of 1983

Table 4-3

Groundwater Levels and Elevations
Lockheed Martin Martin State Airport, Middle River, Maryland

1 Based on an October 2010 survey of all Dump Road Area wells
2 Well has been sealed and abandoned in accordance with state regulations and is no longer in use
NA - Not available or not measured
S - Upper surficial aquifer
I - Intermediate surficial aquifer
D - Lower surficial aquifer
DD - Deep confined aquifer or below the lower surficial aquifer
NAVD88 = North American Vertical Datum of 1988.
NAD83 - North American Datum of 1983

APPENDIX H—CHEMICAL DATA TABLES

U - Not detected at listed detection limit.

B - Laboratory blank contamination.

J - Positive result is considered estimated as a result of technical noncompliance.

L - Positive result is considered to be biased low as a result of technical noncompliance.

K - Positive result is considered to be biased high as a result of technical noncompliance.

ug/l - micrograms per liter.

U - Not detected at listed detection limit.

B - Laboratory blank contamination.

J - Positive result is considered estimated as a result of technical noncompliance.

L - Positive result is considered to be biased low as a result of technical noncompliance.

K - Positive result is considered to be biased high as a result of technical noncompliance.

R - Result is rejected as a result of technical noncompliance.

ug/l - micrograms per liter.

mg/l - milligrams per liter.

U - Not detected at listed detection limit.

B - Laboratory blank contamination.

J - Positive result is considered estimated as a result of technical noncompliance.

L - Positive result is considered to be biased low as a result of technical noncompliance.

K - Positive result is considered to be biased high as a result of technical noncompliance.

R - Result is rejected as a result of technical noncompliance.

ug/l - micrograms per liter.

mg/l - milligrams per liter.

GREATER STRAWBERRY POINT MSA
SAMPLE DELIVERY GROUP (SDG) – 240-1267-1

SAMPLES: 4/Aqueous/VOC

GSP-MW1-061711 GSP-MW2-061711 GSP-MW3-061711
TB-061711

3/Aqueous/SVOC/GRO/DRO/Metals/Perchlorate

GSP-MW1-061711 GSP-MW2-061711 GSP-MW3-061711

Overview

The sample set for Greater Strawberry Point MSA, SDG 240-1267-1 consisted of three (3) aqueous samples and a trip blank analyzed for volatile organic compounds (VOCs). Three (3) aqueous samples were analyzed for semi-volatile organic compounds (SVOCs), total petroleum hydrocarbons (TPH) gasoline and total petroleum hydrocarbons (TPH) diesel, total select metals, dissolved select metals and perchlorate. The select metals were antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, tungsten, vanadium and zinc.

The samples were collected on June 17, 2011 and analyzed by Test America Laboratories Inc. All analyses were conducted in accordance with SW-846 Methods 8260B for VOCs, 8270C for SVOCs, 8015B for TPH (gasoline and diesel), 6010C for metals, 7471B for mercury and MCAWW 314 for perchlorate analytical and reporting protocols.

The data contained in this SDG were validated with regard to the following parameters: data completeness, holding times, GC/MS tuning, initial/continuing calibrations, laboratory method /preparation blank results, surrogate spike recoveries, blank spike/blank spike duplicate results, matrix spike/matrix spike duplicate, internal standard recoveries, chromatographic resolution, ICP interference results, ICP serial dilution results, compound identification, compound quantitation, and detection limits. Areas of concern are listed below.

Major

- VOC initial calibration relative response factors (RRFs) for tert-butyl alcohol and vinyl acetate were less than the 0.05 quality control limit on May 29, 2011 for instrument A3UX16 and the continuing calibrations on June 28, 2011 @ 14:29. The nondetected tert-butyl alcohol and vinyl acetate results were qualified as rejected (UR) in the affected samples.

Minor

- The following VOC contaminants were detected in the trip blank at the following maximum concentrations:

Contaminant	Maximum Concentration (ug/L)	Action Level (ug/L)
Benzene	0.29	1.45
Acetone	2.2	22.0
Toluene	0.26	1.3

An action level of ten times the maximum level for the common laboratory contaminant, acetone, and five times the maximum level for other contaminants has been used to evaluate sample data for blank contamination. Sample aliquot, and dilution factors, if applicable, were taken into consideration when evaluating for blank contamination. Positive results less than the blank action level reported for the above analytes were qualified "B" as a result of laboratory blank contamination.

- The VOC continuing calibration percent difference (%D) for acetone was greater than 50% on June 28, 2011@ 14:29 on instrument A3UX16. The positive acetone result in the trip blank TB-062211 was qualified as estimated (J). The positive acetone results in the samples were qualified due to blank contamination. No further action was taken.

- The TPH as gasoline laboratory method blank 240-6402/19 contained contaminant.

Contaminant	Maximum Concentration (ug/L)	Action Level (ug/L)
TPH as gasoline	37.9	189.5

An action level of 5X the maximum concentration of contaminant was used in order to evaluate the affected samples. Sample aliquot and dilution factors, if applicable, were taken into consideration when evaluating for blank contamination. Positive results less than the blank action level were qualified (B) as a result of laboratory blank contamination.

- The following contaminants were detected in the laboratory method/preparation/continuing calibration blanks at the following maximum concentrations:

Contaminant	Maximum Concentration (ug/L)	Action Level (ug/L)
Antimony [(1)]	0.343	1.72
Chromium [(2)]	0.281	1.41
Cobalt [(3)]	0.243	1.22
Lead [(2)]	0.176	0.88
Molybdenum [(4)]	0.619	3.095
Thallium [(2)]	0.225	1.125
Tungsten [(1)]	0.338	1.69
Zinc [(2)]	0.851	4.255

(1) Maximum concentration of contaminants in the initial calibration blank 200-21675/8 analyzed on July 16, 2011 @ 1:09.
(2) Maximum concentration of contaminant in the method blank 200-20966/1-A affecting all samples both total and dissolved.

(3) Maximum concentration of contaminant in CCB 200-21675/26 analyzed on July 16, 2011 @ 12:05.
(4) Maximum concentration of contaminant in CCB 200-21675/12 analyzed on July 16, 2011 @ 1:47 affecting the total metals.

An action level of 5x the maximum concentration of contaminant was used in order to evaluate the affected samples. Sample aliquot and dilution factors, if applicable, were taken into consideration when evaluating for blank contamination. Positive results less than the blank action level were qualified (B) as a result of laboratory blank contamination.

- The %D in the serial dilution of total and dissolved lead and zinc were greater than 10%. The positive total and dissolved lead and zinc results were qualified as estimated (J).

- Positive results reported below the quantitation limit but above the method detection limit (MDL) were qualified as estimated, (J).

Notes

Form 1s of the VOC Tentatively Identified Compounds (TICs) are included in this SDG in Appendix B. No action was taken on these findings. TICS were qualified as (NJ).

The VOC continuing calibration %Ds for several analytes were greater than the 20% quality control limit but less than 50% on June 28, 2011 @ 14:29 and 14:52. The analytes were trichlorofluoromethane, carbon disulfide, tert-butyl alcohol, vinyl acetate, 2-chloroethyl vinyl ether, trans-1,3-dichloropropene, tetrachloroethene, bromoform, 1,2-dibromo-3-chloropropane, naphthalene, 1,2,3-trichlorobenzene, ethyl tert butyl ether and tert amyl methyl ether. No action was taken on the nondetected results of the aforementioned analytes in the affected samples.

The percent recovery (%R) of tert-butyl alcohol was less than the lower quality control limit in the laboratory control sample associated with batch 240-6415/4. No further action was taken on the nondetected tert-butyl alcohol results which were qualified due to a more serious noncompliance.

Naphthalene and hexachlorobutadiene were reported in both the VOC and the SVOC fractions.

Nondetected results were reported to the MDL.

Executive Summary

Laboratory Performance: The VOC RRFs for tert-butyl alcohol and vinyl acetate were less than the quality control limit resulting in the rejection of nondetected results. VOC, TPH as diesel and gasoline and metals results were qualified due to method blank contamination. Continuing calibration verification percent difference exceeded quality control limits in the VOC fraction for acetone. The LCS %R of tert-butyl alcohol was less than quality control limits.

Other Factors Affecting Data Quality: Trip blank contained acetone, benzene and toluene. The serial dilution %Ds for total and dissolved lead and zinc exceeded quality control limits. Positive results reported below the quantitation limit but above the method detection limit were qualified as estimated, (J).

The data for these analyses were reviewed with reference to Region III modifications to U.S. EPA National Functional Guidelines for Organic Data Validation (Sept. 1994) and U.S. EPA National Functional Guidelines for Inorganic Data Validation (April 1993). The text of this report has been formulated to address only those problem areas affecting data quality.

Appendix A – Qualified Analytical Results
Appendix B – Results as Reported by the Laboratory
Appendix C – Support Documentation

Appendix A

Qualified Analytical Results

Data Validation Qualifier Codes:

A = Lab Blank Contamination
B = Field Blank Contamination
C = Calibration Noncompliance (e.g. % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
C01 = GC/MS Tuning Noncompliance
D = MS/MSD Recovery Noncompliance
E = LCS/LCSD Recovery Noncompliance
F = Lab Duplicate Imprecision
G = Field Duplicate Imprecision
H = Holding Time Exceedance
I = ICP Serial Dilution Noncompliance
J = GFAA PDS - GFAA MSA's $r < 0.995$
K = ICP Interference - includes ICS % R Noncompliance
L = Instrument Calibration Range Exceedance
M = Sample Preservation Noncompliance
N = Internal Standard Noncompliance
N01 = Internal Standard Recovery Noncompliance Dioxins
N02 = Recovery Standard Noncompliance Dioxins
N03 = Clean-up Standard Noncompliance Dioxins
O = Poor Instrument Performance (e.g. base-line drifting)
P = Uncertainty near detection limit (< 2 x IDL for inorganics and <CRQL for organics)
Q = Other problems (can be any number of issues; e.g. poor chromatography,interferences, etc.)
R = Surrogates Recovery Noncompliance
S = Pesticide/PCB Resolution
T = % Breakdown Noncompliance for DDT and Endrin
U = % Difference between columns/detectors >25% for positive results determined via GC/HPLC
V = Non-linear calibrations; correlation coefficient $r < 0.995$
W = EMPC result
X = Signal to noise response drop
Y = Percent solids <30%
Z = Uncertainty at 2 sigma deviation is greater than sample activity

CASE NARRATIVE

Client: Tetra Tech NUS Inc

Project: MSA Greater Strawberry Point PH. II 2011

Report Number: 240-1267-1

With the exceptions noted as flags or footnotes, standard analytical protocols were followed in the analysis of the samples and no problems were encountered or anomalies observed. In addition all laboratory quality control samples were within established control limits, with any exceptions noted below. Each sample was analyzed to achieve the lowest possible reporting limit within the constraints of the method. In some cases, due to interference or analytes present at high concentrations, samples were diluted. For diluted samples, the reporting limits are adjusted relative to the dilution required.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the application methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory.

Calculations are performed before rounding to avoid round-off errors in calculated results.

All holding times were met and proper preservation noted for the methods performed on these samples, unless otherwise detailed in the individual sections below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by the presence of a % solids value in the method header.

This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

RECEIPT

The samples were received on 06/18/2011; the samples arrived in good condition, properly preserved and on ice. The temperature of the coolers at receipt was C.

Multiple TestAmerica laboratories were used to support this project. Narrative for TestAmerica West Sacramento (Perchlorate) is provided in the lab's report in the Subcontract section of this report. TestAmerica Burlington's narrative for ICP/MS Metals is incorporated herein. See the Method Summary for additional information.

VOLATILE ORGANIC COMPOUNDS (GC-MS)

Samples TB-061711 (240-1267-1), GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4) were analyzed for volatile organic compounds (GC-MS) in accordance with EPA SW-846 Method 8260B. The samples were analyzed on 06/28/2011.

tert-Butyl alcohol failed the recovery criteria low for LCS 240-6415/4. Refer to the QC report for details.

No other difficulties were encountered during the volatiles analyses. All other quality control parameters were within the acceptance limits.

SEMI VOLATILES

Samples GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4) were analyzed for semivolatiles in accordance with EPA SW 8270D. The samples were analyzed on 07/22/2011.

No difficulties were encountered during the semivolatiles analyses. All quality control parameters were within the acceptance limits.

GRO (C6-C10)

Samples GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4) were analyzed for gas range organics in accordance with EPA SW-846 Method 8015B - GRO. The samples were analyzed on 06/29/2011.

Total Petroleum Hydrocarbons (C6-C10) was detected in method blank MB 240-6402/19 at a level exceeding the reporting limit. If the associated sample reported a result above the MDL and/or RL, the result has been "B" flagged. Refer to the QC report for details.

No other difficulties were encountered during the GRO analyses. All other quality control parameters were within the acceptance limits.

DRO (C10-C32)

Samples GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4) were analyzed for Diesel Range Organics (DRO) in accordance with EPA Method 8015B. The samples were analyzed on 06/24/2011.

Surrogates are added during the extraction process prior to dilution. When the sample dilution is 5X or greater, surrogate recoveries are diluted out and no corrective action is required.

No difficulties were encountered during the Diesel Range Organics (DRO) analyses. All quality control parameters were within the acceptance limits.

DISSOLVED METALS (ICPMS)

Samples GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4) were analyzed for metals (ICPMS) in accordance with EPA SW-846 Method 6020. The samples were analyzed on 07/16/2011.

The serial dilution performed for the following samples were outside control limits for Pb: (240-1267-4 SD), GSP-MW3-061711 (240-1267-4)

The internal standard for As, Mo, and Se were reassociated from Y to In for analytical sequence 080111-06b, due to the presence of isobaric interference on the Y line. Data flags in batch 21765 for Y internal standard failures were removed. All results in the batch for As, Mo, and Se are based on internal standard responses for Indium.

No difficulties were encountered during the metals analyses. All quality control parameters were within the acceptance limits.

TOTAL METALS (ICPMS)

Samples GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4) were analyzed for total metals (ICPMS) in accordance with EPA SW-846 Method 6020. The samples were analyzed on 07/16/2011.

Several analytes were detected in method blank MB 200-20966/1-A at levels that were above the method detection limit but below the reporting limit. The values should be considered estimates, and have been flagged "J". If the associated sample reported a result above the MDL and/or RL, the result has been "B" flagged. Refer to the QC report for details.

A deviation from the Standard Operating Procedure (SOP) occurred. Eleven injections were analyzed between CCB26 and CCV38. Bracketing CCV/CCB were within control limits. The eleventh sample was not reported from this batch 21675. The proceeding ten samples were reported. Samples reported in this job include: (240-1267-4 SD), (CCV 200-21675/38), GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4)

The internal standard for As, Mo, and Se were reassociated from Y to In for analytical sequence 080111-06b, due to the presence of isobaric interference on the Y line. Data flags in batch 21765 for Y internal standard failures were removed. All results in the batch for As, Mo, and Se are based on internal standard responses for Indium.

The serial dilution performed for the following sample(s) was outside control limits for Pb and Zinc in batch 21675: (240-1267-4 SD)

No other difficulties were encountered during the metals analyses. All other quality control parameters were within the acceptance limits.

DISSOLVED MERCURY (CVAA)

Samples GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4) were analyzed for dissolved mercury (CVAA) in accordance with EPA SW-846 Methods 7470A. The samples were analyzed on 07/08/2011.

No difficulties were encountered during the mercury analyses. All quality control parameters were within the acceptance limits.

TOTAL MERCURY

Samples GSP-MW1-061711 (240-1267-2), GSP-MW2-061711 (240-1267-3) and GSP-MW3-061711 (240-1267-4) were analyzed for total mercury in accordance with EPA SW-846 Methods 7470A. The samples were analyzed on 07/08/2011.

No difficulties were encountered during the mercury analyses. All quality control parameters were within the acceptance limits.

Question	Answer	Comment
Radioactivity either was not measured or, if measured, is at or below background	N/A	
The cooler's custody seal, if present, is intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	2.7 2.2
Cooler Temperature is recorded.	True	
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the sample IDs on the containers and the COC.	True	
Samples are received within Holding Time.	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
VOA sample vials do not have headspace or bubble is <6mm (1/4") in diameter.	True	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

Case Narrative

TestAmerica West Sacramento Project Number G1F210484

General Comments
Samples 1-3 were received by the laboratory at 1 degrees C. Wet ice was used as the cooling agent.

Samples 15 & 16 were received by the laboratory at 25 degrees C. Wet ice was used as the cooling agent.

WATER, 314.0, Perchlorate
Sample(s): 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16
A mid continuing calibration blank had a positive result of 0.623 ug/L. Only sample 9 had a positive result for perchlorate. This sample was re-analyzed and the re-analysis results for this sample were reported.

Sample(s): 6, 13
These samples were analyzed at dilutions due to matrix interferences.

There were no other anomalies associated with this project.

Notes(s):

- The analytical results of the samples listed above are presented on the following pages.
- All calculations are performed before rounding to avoid round-off errors in calculated results.
- Results noted as "ND" were not detected at or above the stated limit.
- This report must not be reproduced, except in full, without the written approval of the laboratory.
- Results for the following parameters are never reported on a dry weight basis: color, corrosivity, density, flashpoint, ignitability, layers, odor, paint filter test, pH, porosity, pressure, reactivity, redox potential, specific gravity, spot tests, solids, solubility, temperature, viscosity, and weight.

SUBJECT: **ORGANIC DATA VALIDATION - VOC/SVOC/TPH (GASOLINE & DIESEL)**
MARTIN STATE AIRPORT – GREATER STRAWBERRY POINT
SAMPLE DELIVERY GROUP (SDG) – 240-1287-1

SAMPLES: 4/Water/VOC/

GSP-MW-4-062011 GSP-MW-5-062011 GSP-MW-6-062011 TB-062011

3/Water/SVOC/TPH

GSP-MW-4-062011 GSP-MW-5-062011 GSP-MW-6-062011

Overview

The sample set for Greater Strawberry Point, SDG 240-1287-1 consisted of three (3) aqueous environmental samples analyzed for Target Compound List (TCL) volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), and total petroleum hydrocarbons (TPHs) gasoline and diesel. One (1) trip blank was analyzed for VOCs.

The samples were collected on June 20, 2011 and analyzed by Test America Laboratories Inc. All analyses were conducted in accordance with SW-846 Methods 8260B for VOCs, 8270D for SVOCs, and 8015B for TPH (gasoline and diesel) analytical and reporting protocols.

The data contained in this SDG were validated with regard to the following parameters: data completeness, holding times, GC/MS tuning, initial/continuing calibrations, laboratory method blank results, surrogate spike recoveries, blank spike/blank spike duplicate results, matrix spike/matrix spike duplicate, internal standard recoveries, chromatographic resolution, compound identification, compound quantitation, and detection limits. Areas of concern are listed below.

Major

- The VOC initial calibration relative response factors (RRFs) for tert-butyl alcohol and vinyl acetate were less than the 0.05 quality control limit on 05/29/2011 for instrument A3UX16 and the continuing calibrations on 05/29/2011 at 17:29 and 6/29/2011 at12:41. The nondetected tert-butyl alcohol and vinyl acetate results were qualified as rejected (UR) in all samples.

Minor

- VOC continuing calibration percent difference (%D) was >20% (but <50%) for acetone on 06/29/2011 at 12:41 affecting all samples. Positive results were qualified as estimated, "J". No action was taken for nondetected results.

- TPH as gasoline was present in the laboratory method blank the following maximum concentration:

Contaminant	Maximum Concentration (ug/L)	Action Level (ug/L)
TPH as gasoline	30.9	155

An action level of 5x the maximum concentration of contaminant was used in order to evaluate the affected samples. Positive results less than the action limit were qualified as (B) due to blank contamination.

- Positive results reported below the quantitation limit but above the method detection limit (MDL) were qualified as estimated, (J).

Notes

Form 1s of the VOC Tentatively Identified Compounds (TICs) identified by the laboratory are included in this SDG in Appendix B. TICs were qualified as presumptively present.

In the VOC continuing calibration %Ds for 2-chloroethyl vinyl ether, bromoform, bromomethane, methyl tert-butyl ether, 2,2-dichloropropane, 1,2-dibromo-3-chloropropane, 1,2,4-trichlorobenzene, naphthalene, and 1,2,3-trichlorobenzene were >20% (but <50%) on 06/29/2011 at 12:41. No action was taken as all results were nondetects.

In the VOC continuing calibration %Ds for ethyl tert-butyl ether and tert-amyl methyl ether were >20% (but <50%) on 06/29/2011 at 13;04. No action was taken as all results were nondetects.

The following VOC contaminant was detected in the laboratory method blanks at the following maximum concentration:

Contaminant	Maximum Concentration (ug/L)	Action Level (ug/L)
Naphthalene	0.264	1.32

Five times the maximum contaminant level has been used to evaluate sample data for blank contamination. Sample aliquot and dilution factors, if applicable, were taken into consideration when evaluating for blank contamination. No action was necessary as all results for naphthalene were nondetects.

The laboratory control sample (LCS) had a percent recovery (%R) less than the lower quality control limit for tert-buyl alcohol. No action was taken as the results were qualified as rejected due to calibration noncompliance.

Matrix spike and matrix spike duplicate percent recovery was 0% for 2-chloroethyl vinyl ether and less than quality control limits for tert-butyl alcohol. No action was taken because the sample analyzed was not included in this SDG.

Nondetected results are reported to the method detection limit (MDL).

Executive Summary

Laboratory Performance: The VOC RRFs for tert-butyl alcohol and vinyl acetate were less than the quality control limit resulting in the rejection of nondetected results. TPH as gasoline results were qualified due to method blank contamination. Continuing calibration verification percent differences exceeded quality control limits in the VOC fraction for acetone resulting in the qualification data.

Other Factors Affecting Data Quality: Positive results reported below the quantitation limit but above the method detection limit were qualified as estimated, (J).

The data for these analyses were reviewed with reference to Region III modifications to U.S. EPA National Functional Guidelines for Organic Data Validation (Sept. 1994). The text of this report has been formulated to address only those problem areas affecting data quality.

Attachments:
Appendix A – Qualified Analytical Results
Appendix B – Results as Reported by the Laboratory
Appendix C – Support Documentation

Appendix A

Qualified Analytical Results

Data Validation Qualifier Codes:

A = Lab Blank Contamination
B = Field Blank Contamination
C = Calibration Noncompliance (e.g. % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
C01 = GC/MS Tuning Noncompliance
D = MS/MSD Recovery Noncompliance
E = LCS/LCSD Recovery Noncompliance
F = Lab Duplicate Imprecision
G = Field Duplicate Imprecision
H = Holding Time Exceedance
I = ICP Serial Dilution Noncompliance
J = GFAA PDS-GFAA MSA's r < 0.995 / ICP PDS Recovery Noncompliance
K = ICP Interference - includes ICS % R Noncompliance
L = Instrument Calibration Range Exceedance
M = Sample Preservation Noncompliance
N = Internal Standard Noncompliance
N01 = Internal Standard Recovery Noncompliance Dioxins
N02 = Recovery Standard Noncompliance Dioxins
N03 = Clean-up Standard Noncompliance Dioxins
O = Poor Instrument Performance (e.g. base-line drifting)
P = Uncertainty near detection limit (< 2 x IDL for inorganics and <CRQL for organics)
Q = Other problems (can encompass a number of issues; e.g. chromatography,interferences, etc.)
R = Surrogates Recovery Noncompliance
S = Pesticide/PCB Resolution
T = % Breakdown Noncompliance for DDT and Endrin
U = % Difference between columns/detectors >25% for positive results determined via GC/HPLC
V = Non-linear calibrations; correlation coefficient r < 0.995
W = EMPC result
X = Signal to noise response drop
Y = Percent solids <30%
Z = Uncertainty at 2 sigma deviation is greater than sample activity

CASE NARRATIVE

Client: Tetra Tech NUS Inc

Project: MSA Greater Strawberry Point PH. II 2011

Report Number: 240-1287-1

With the exceptions noted as flags or footnotes, standard analytical protocols were followed in the analysis of the samples and no problems were encountered or anomalies observed. In addition all laboratory quality control samples were within established control limits, with any exceptions noted below. Each sample was analyzed to achieve the lowest possible reporting limit within the constraints of the method. In some cases, due to interference or analytes present at high concentrations, samples were diluted. For diluted samples, the reporting limits are adjusted relative to the dilution required.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the application methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory.

Calculations are performed before rounding to avoid round-off errors in calculated results.

All holding times were met and proper preservation noted for the methods performed on these samples, unless otherwise detailed in the individual sections below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by the presence of a % solids value in the method header.

This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

RECEIPT

The samples were received on 06/21/2011; the samples arrived in good condition, properly preserved and on ice. The temperature of the coolers at receipt was 2.6 C.

Multiple TestAmerica laboratories were used to support this project. Narrative for TestAmerica West Sacramento (Perchlorate) is provided in the lab's report in the Subcontract section of this report. TestAmerica Burlington's narrative for ICP/MS Metals is incorporated herein. See the Method Summary for additional information.

VOLATILE ORGANIC COMPOUNDS (GC-MS)

Samples TB-062011 (240-1287-1), GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for volatile organic compounds (GC-MS) in accordance with EPA SW-846 Method 8260B. The samples were analyzed on 06/29/2011.

Naphthalene was detected in method blank MB 240-6573/5 at a level that was above the method detection limit but below the reporting limit. The value should be considered an estimate, and has been flagged "J". If the associated sample reported a result above the MDL and/or RL, the result has been "B" flagged. Refer to the QC report for details.

The laboratory control sample for batch 240-6573/4 failed the recovery criteria low for tert-Butyl alcohol, and exceeded control limits for 2Methyl-2propanol. 2Methyl-2propanol has been identified as a poor performing analyte when analyzed using this method; therefore, re-extraction/re-analysis was not performed. Batch precision also exceeded control limits for this analyte. These results have been reported and qualified. Refer to the QC report for details.

No other difficulties were encountered during the volatiles analyses. All other quality control parameters were within the acceptance limits.

SEMI VOLATILES

Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for Semivolates in accordance with EPA SW 8270D. The samples were analyzed on 06/28/2011 and 06/30/2011.

There was no client requested matrix spike/matrix spike duplicate (MS/MSD) for batch 5615.

No other difficulties were encountered during the semi-volatiles analyses. All quality control parameters were within the acceptance limits.

GRO (C6-C10)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for gas range organics in accordance with EPA SW-846 Method 8015B - GRO. The samples were analyzed on 06/24/2011.

Total Petroleum Hydrocarbons (C6-C10) was detected in method blank MB 240-6019/6 at a level exceeding the reporting limit. If the associated sample reported a result above the MDL and/or RL, the result has been "B" flagged. Refer to the QC report for details.

No other difficulties were encountered during the GRO analyses. All other quality control parameters were within the acceptance limits.

DRO (C10-C32)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for Diesel Range Organics (DRO) in accordance with EPA Method 8015B. The samples were analyzed on 06/24/2011.

Surrogates are added during the extraction process prior to dilution. When the sample dilution is 5X or greater, surrogate recoveries are diluted out and no corrective action is required.

There was no client requested matrix spike/matrix spike duplicate (MS/MSD) for batch 5625.

No other difficulties were encountered during the Diesel Range Organics (DRO) analyses. All quality control parameters were within the acceptance limits.

METALS (ICPMS)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for metals (ICPMS) in accordance with EPA SW-846 Method 6020. The samples were analyzed on 07/16/2011 and 08/04/2011.

The internal standard for As, Mo, and Se were re-associated from Y to In for analytical sequence 080111-06b, due to the presence of isobaric interference on the Y line. All results in the batch for As, Mo, and Se are based on internal standard responses for Indium.

A deviation from the Standard Operating Procedure (SOP) occurred. Eleven injections were analyzed between CCB26 and CCV38. Bracketing CCV/CCB were within control limits. The eleventh sample was not reported from this batch 21675. The proceeding ten (10) samples were reported. The following samples were reported in this job: GSP-MW-6-062011 (240-1287-4 SD), (CCV 200-21675/38), GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4)

The internal standard for As, Mo, and Se were re-associated from Y to In for analytical sequence 080111-06b, due to the presence of isobaric interference on the Y line. Data flags in batch 21765 for Y internal standard failures were removed. All results in the batch for As, Mo, and Se are based on internal standard responses for Indium.

A negative result was observed at the magnitude of the RL for Nickel in sample GSP-MW-6-062011 (240-1287-4).

The internal standard In was associated with As, Mo, and Se in analytical sequence 080411-02E. All injections results for As, Mo, and Se in the sequence, 080411-02E, and LIMS batch, 22993, were calculated based upon the Indium internal standard response. Yttrium was disassociated to sample results for these elements due to the possibility of isobaric interference

No other difficulties were encountered during the metals analyses. All quality control parameters were within the acceptance limits.

TOTAL METALS (ICPMS)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for total metals (ICPMS) in accordance with EPA SW-846 Method 6020. The samples were analyzed on 07/16/2011.

Several analytes were detected in method blank MB 200-20966/1-A at levels that were above the method detection limit but below the reporting limit. The values should be considered estimates, and have been flagged "J". If the associated sample reported a result above the MDL and/or RL, the result has been "B" flagged. Refer to the QC report for details.

No other difficulties were encountered during the metals analyses. All other quality control parameters were within the acceptance limits.

DISSOLVED MERCURY (CVAA)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for dissolved mercury (CVAA) in accordance with EPA SW-846 Methods 7470A. The samples were analyzed on 07/08/2011.

No difficulties were encountered during the mercury analyses. All quality control parameters were within the acceptance limits.

TOTAL MERCURY

Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for total mercury in accordance with EPA SW-846 Methods 7470A. The samples were analyzed on 07/08/2011.

No difficulties were encountered during the mercury analyses. All quality control parameters were within the acceptance limits.

MARTIN STATE AIRPORT – GREATER STRAWBERRY POINT
SDG 240-1287-1

SAMPLES: 3/Water/
GSP-MW-4-062011 GSP-MW-5-062011 GSP-MW-6-062011

Overview

The sample set for Greater Strawberry Point, SDG 240-1287-1, consists of three (3) aqueous environmental samples. This SDG contained no field duplicate pairs.

All samples were analyzed for select total and dissolved metals: antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, mercury, molybdenum, nickel, selenium, silver, thallium, tungsten, vanadium, and zinc and perchlorate. The samples were collected by Tetra Tech NUS on June 20, 2011 and analyzed by Test America. Metals analyses were conducted using SW-846 method 6020. Mercury analyses were conducted using SW-846 method 7470A. Perchlorate analyses were conducted using EPA method 314.0.

The findings offered in this report are based upon a general review of all available data. The data review was based on data completeness, holding times, initial and continuing calibration verification results, laboratory method / preparation blank results, ICP interference results, laboratory control sample recoveries, ICP serial dilution results, internal standard recoveries, detection limits and analyte quantitation.

Areas of concern with respect to data quality are listed below.

Major Problems – None.

Minor Problems-

- The following contaminants were detected in preparation blanks at the following maximum concentrations:

Analyte	Maximum Concentration	Action Level
Antimony	0.091 ug/L	0.46 ug/L
Chromium	0.281 ug/L	1.41 ug/L
Cobalt	0.192 ug/L	0.96 ug/L
Lead	0.176 ug/L	0.88 ug/L
Thallium	0.225 ug/L	1.13 ug/L
Tungsten	0.172 ug/L	0.86 ug/L
Zinc	0.851 ug/L	4.26 ug/L

An action level of 5X the maximum contaminant level has been used to evaluate sample data for blank contamination. Sample aliquot and dilution factors, if applicable, were taken into consideration when evaluating for blank contamination. Positive results less than the blank action level reported for were qualified "B" as a result of laboratory blank contamination.

- The following contaminants were detected in calibration blanks at the following maximum concentrations:

Analyte	Maximum Concentration	Action Level
Antimony[(1)]	0.113 ug/L	0.57 ug/L
Antimony[(2)]	0.121 ug/L	0.61 ug/L
Arsenic[(3)]	0.187 ug/L	0.94 ug/L
Cobalt[(1)]	0.236 ug/L	1.18 ug/L
Cobalt[(2)]	0.243 ug/L	1.22 ug/L
Thallium[(1)]	0.233 ug/L	1.17 ug/L
Thallium[(2)]	0.230 ug/L	1.15 ug/L
Thallium[(3)]	0.195 ug/L	0.98 ug/L
Tungsten[(1)]	0.185 ug/L	0.93 ug/L

(1) Maximum concentration found in a calibration blank affecting total samples.
(2) Maximum concentration found in a calibration blank affecting dissolved samples GSP-MW-4-062011 and GSP-MW-5-062011.
(3) Maximum concentration found in a calibration blank affecting dissolved sample GSP-MW-6-062011.

An action level of 5X the maximum contaminant level has been used to evaluate sample data for blank contamination. Sample aliquot and dilution factors, if applicable, were taken into consideration when evaluating for blank contamination. Positive results less than the blank action level reported for were qualified "B" as a result of laboratory blank contamination.

- Positive results greater than the method detection limit but less than the reporting limit were qualified as estimated (J).

Notes

The percent relative intensity for internal standard Y-89 for total samples GSP-MW-4-062011 and GSP-MW-5-062011 and dissolved sample GSP-MW-4-062011 was greater than quality control limits. Affected analytes arsenic, molybdenum, and selenium in these samples were quantified using a different internal standard (In-115); therefore, no validation action was taken.

Nondetected results are reported to the method detection limit (MDL).

Executive Summary

Laboratory Performance: Calibration and preparation blank contamination resulted in the qualification of sample results.

Other Factors Affecting Data Quality: None.

The data for these analyses were reviewed with reference to Region III modifications to the "National

Functional Guidelines for Inorganic Data Validation", April 1993. The text of this report has been formulated to address only those problem areas affecting data quality.

Attachments:
Appendix A – Qualified Analytical Results
Appendix B – Results as Reported by the Laboratory
Appendix C – Support Documentation

APPENDIX A
QUALIFIED ANALYTICAL RESULTS

Data Validation Qualifier Codes:

A = Lab Blank Contamination
B = Field Blank Contamination
C = Calibration Noncompliance (e.g. % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
C01 = GC/MS Tuning Noncompliance
D = MS/MSD Recovery Noncompliance
E = LCS/LCSD Recovery Noncompliance
F = Lab Duplicate Imprecision
G = Field Duplicate Imprecision
H = Holding Time Exceedance
I = ICP Serial Dilution Noncompliance
J = GFAA PDS-GFAA MSA's r < 0.995 / ICP PDS Recovery Noncompliance
K = ICP Interference - includes ICS % R Noncompliance
L = Instrument Calibration Range Exceedance
M = Sample Preservation Noncompliance
N = Internal Standard Noncompliance
N01 = Internal Standard Recovery Noncompliance Dioxins
N02 = Recovery Standard Noncompliance Dioxins
N03 = Clean-up Standard Noncompliance Dioxins
O = Poor Instrument Performance (e.g. base-line drifting)
P = Uncertainty near detection limit (< 2 x IDL for inorganics and <CRQL for organics)
Q = Other problems (can encompass a number of issues; e.g. chromatography,interferences, etc.)
R = Surrogates Recovery Noncompliance
S = Pesticide/PCB Resolution
T = % Breakdown Noncompliance for DDT and Endrin
U = % Difference between columns/detectors >25% for positive results determined via GC/HPLC
V = Non-linear calibrations; correlation coefficient r < 0.995
W = EMPC result
X = Signal to noise response drop
Y = Percent solids <30%
Z = Uncertainty at 2 sigma deviation is greater than sample activity

CASE NARRATIVE

Client: Tetra Tech NUS Inc

Project: MSA Greater Strawberry Point PH. II 2011

Report Number: 240-1287-1

With the exceptions noted as flags or footnotes, standard analytical protocols were followed in the analysis of the samples and no problems were encountered or anomalies observed. In addition all laboratory quality control samples were within established control limits, with any exceptions noted below. Each sample was analyzed to achieve the lowest possible reporting limit within the constraints of the method. In some cases, due to interference or analytes present at high concentrations, samples were diluted. For diluted samples, the reporting limits are adjusted relative to the dilution required.

TestAmerica North Canton attests to the validity of the laboratory data generated by TestAmerica facilities reported herein. All analyses performed by TestAmerica facilities were done using established laboratory SOPs that incorporate QA/QC procedures described in the application methods. TestAmerica's operations groups have reviewed the data for compliance with the laboratory QA/QC plan, and data have been found to be compliant with laboratory protocols unless otherwise noted below.

The test results in this report meet all NELAP requirements for parameters for which accreditation is required or available. Any exceptions to NELAP requirements are noted in this report. Pursuant to NELAP, this report may not be reproduced, except in full, without the written approval of the laboratory.

Calculations are performed before rounding to avoid round-off errors in calculated results.

All holding times were met and proper preservation noted for the methods performed on these samples, unless otherwise detailed in the individual sections below.

All solid sample results are reported on an "as received" basis unless otherwise indicated by the presence of a % solids value in the method header.

This laboratory report is confidential and is intended for the sole use of TestAmerica and its client.

RECEIPT

The samples were received on 06/21/2011; the samples arrived in good condition, properly preserved and on ice. The temperature of the coolers at receipt was 2.6 C.

Multiple TestAmerica laboratories were used to support this project. Narrative for TestAmerica West Sacramento (Perchlorate) is provided in the lab's report in the Subcontract section of this report. TestAmerica Burlington's narrative for ICP/MS Metals is incorporated herein. See the Method Summary for additional information.

VOLATILE ORGANIC COMPOUNDS (GC-MS)

Samples TB-062011 (240-1287-1), GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for volatile organic compounds (GC-MS) in accordance with EPA SW-846 Method 8260B. The samples were analyzed on 06/29/2011.

Naphthalene was detected in method blank MB 240-6573/5 at a level that was above the method detection limit but below the reporting limit. The value should be considered an estimate, and has been flagged "J". If the associated sample reported a result above the MDL and/or RL, the result has been "B" flagged. Refer to the QC report for details.

The laboratory control sample for batch 240-6573/4 failed the recovery criteria low for tert-Butyl alcohol, and exceeded control limits for 2Methyl-2propanol. 2Methyl-2propanol has been identified as a poor performing analyte when analyzed using this method; therefore, re-extraction/re-analysis was not performed. Batch precision also exceeded control limits for this analyte. These results have been reported and qualified. Refer to the QC report for details.

No other difficulties were encountered during the volatiles analyses. All other quality control parameters were within the acceptance limits.

SEMI VOLATILES

Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for Semivolates in accordance with EPA SW 8270D. The samples were analyzed on 06/28/2011 and 06/30/2011.

There was no client requested matrix spike/matrix spike duplicate (MS/MSD) for batch 5615.

No other difficulties were encountered during the semi-volatiles analyses. All quality control parameters were within the acceptance limits.

GRO (C6-C10)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for gas range organics in accordance with EPA SW-846 Method 8015B - GRO. The samples were analyzed on 06/24/2011.

Total Petroleum Hydrocarbons (C6-C10) was detected in method blank MB 240-6019/6 at a level exceeding the reporting limit. If the associated sample reported a result above the MDL and/or RL, the result has been "B" flagged. Refer to the QC report for details.

No other difficulties were encountered during the GRO analyses. All other quality control parameters were within the acceptance limits.

DRO (C10-C32)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for Diesel Range Organics (DRO) in accordance with EPA Method 8015B. The samples were analyzed on 06/24/2011.

Surrogates are added during the extraction process prior to dilution. When the sample dilution is 5X or greater, surrogate recoveries are diluted out and no corrective action is required.

There was no client requested matrix spike/matrix spike duplicate (MS/MSD) for batch 5625.

No other difficulties were encountered during the Diesel Range Organics (DRO) analyses. All quality control parameters were within the acceptance limits.

METALS (ICPMS)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for metals (ICPMS) in accordance with EPA SW-846 Method 6020. The samples were analyzed on 07/16/2011 and 08/04/2011.

The internal standard for As, Mo, and Se were re-associated from Y to In for analytical sequence 080111-06b, due to the presence of isobaric interference on the Y line. All results in the batch for As, Mo, and Se are based on internal standard responses for Indium.

A deviation from the Standard Operating Procedure (SOP) occurred. Eleven injections were analyzed between CCB26 and CCV38. Bracketing CCV/CCB were within control limits. The eleventh sample was not reported from this batch 21675. The proceeding ten (10) samples were reported. The following samples were reported in this job: GSP-MW-6-062011 (240-1287-4 SD), (CCV 200-21675/38), GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4)

The internal standard for As, Mo, and Se were re-associated from Y to In for analytical sequence 080111-06b, due to the presence of isobaric interference on the Y line. Data flags in batch 21765 for Y internal standard failures were removed. All results in the batch for As, Mo, and Se are based on internal standard responses for Indium.

A negative result was observed at the magnitude of the RL for Nickel in sample GSP-MW-6-062011 (240-1287-4).

The internal standard In was associated with As, Mo, and Se in analytical sequence 080411-02E. All injections results for As, Mo, and Se in the sequence, 080411-02E, and LIMS batch, 22993, were calculated based upon the Indium internal standard response. Yttrium was disassociated to sample results for these elements due to the possibility of isobaric interference

No other difficulties were encountered during the metals analyses. All quality control parameters were within the acceptance limits.

TOTAL METALS (ICPMS)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for total metals (ICPMS) in accordance with EPA SW-846 Method 6020. The samples were analyzed on 07/16/2011.

Several analytes were detected in method blank MB 200-20966/1-A at levels that were above the method detection limit but below the reporting limit. The values should be considered estimates, and have been flagged "J". If the associated sample reported a result above the MDL and/or RL, the result has been "B" flagged. Refer to the QC report for details.

No other difficulties were encountered during the metals analyses. All other quality control parameters were within the acceptance limits.

DISSOLVED MERCURY (CVAA)
Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for dissolved mercury (CVAA) in accordance with EPA SW-846 Methods 7470A. The samples were analyzed on 07/08/2011.

No difficulties were encountered during the mercury analyses. All quality control parameters were within the acceptance limits.

TOTAL MERCURY

Samples GSP-MW-4-062011 (240-1287-2), GSP-MW-5-062011 (240-1287-3) and GSP-MW-6-062011 (240-1287-4) were analyzed for total mercury in accordance with EPA SW-846 Methods 7470A. The samples were analyzed on 07/08/2011.

No difficulties were encountered during the mercury analyses. All quality control parameters were within the acceptance limits.

Case Narrative

TestAmerica West Sacramento Project Number G1F210484B

WATER, 314.0, Perchlorate
Sample(s): 4, 5, 6
A mid continuing calibration blank had a positive result of 0.623 ug/L. Since the associated sample results were all non-detect, no corrective action was performed.

Sample(s): 6
This sample was analyzed at a dilution due to matrix interferences.

There were no other anomalies associated with this project.
