Re: Transmittal of the Frog Mortar Creek Groundwater-Discharge Characterization Report
Martin State Airport, 701 Wilson Point Road, Middle River, Maryland

Dear Mr. Carroll:

For your use and reference, please find enclosed two hard copies with CDs of the above-referenced document. This document presents the data collected to further characterize the distribution and discharge of contaminated groundwater emanating from the Dump Road Area to Frog Mortar Creek.

If you have any questions or require any additional information please contact me by phone at 240-676-5392, or via e-mail at paul.calligan@lmco.com.

Sincerely,

Paul E. Calligan, P.G.

Section 1
Introduction

On behalf of Lockheed Martin Corporation (Lockheed Martin), Tetra Tech, Inc. (Tetra Tech) has prepared this report describing an investigation to further characterize the distribution and discharge of contaminated groundwater emanating from the Dump Road Area (DRA) to Frog Mortar Creek, a tidal creek adjacent to Martin State Airport (MSA) in Middle River, Maryland (see Figure 1-1). The study included the deployment and retrieval of water-level data loggers, and the deployment, retrieval, and chemical analyses of passive flux-meters (PFMs) installed in Frog Mortar Creek sediment. Tetra Tech conducted the investigation in conjunction with the University of Florida. The results of this investigation can be used to evaluate and optimize future interim remedial action measures for groundwater.

Measuring and quantifying groundwater discharge to creek sediment is challenging and complex, because measurement techniques are limited. Heterogeneous stratigraphy, creek-bottom sediment-substrates, variations and reversals in hydraulic heads, varying discharge rates, and the reversal of flow direction in tidal areas make quantification difficult. Therefore, this study aims to identify discernible differences in groundwater discharge to Frog Mortar Creek by using passive flux-meters and water-level measurements, and, to the extent possible, to quantify water and contaminant-mass flux. Passive flux-meters were deployed to establish a relative baseline measurement of contaminant flux in creek sediment before the installation and startup of an interim groundwater remediation system.

The proposed interim remedial action will mitigate the discharge of contaminated groundwater from the Dump Road Area to Frog Mortar Creek by using groundwater extraction wells and aboveground groundwater treatment. Groundwater pumping along the eastern boundary of the Dump Road Area via wells is designed to create a hydraulic barrier that will prevent groundwater contaminants from discharging to Frog Mortar Creek. The interim remedial action is expected to reduce the contaminant flux from the Dump Road Area to the extent that federal and state ambient water quality criteria in Frog Mortar Creek are achieved, and surface water use advisories are not required by the Maryland Department of the Environment (MDE).

The design of the groundwater extraction system was aided by computer simulations that used a calibrated, numerical groundwater model developed for the site. Additional information regarding the distribution of contaminant-mass flux and a baseline quantification of mass discharge from this study is expected to help advance the numerical and conceptual site model, optimize operation of the groundwater interim remedial action, and help determine when active operations may be curtailed or concluded. Field-study results are expected to identify preferential groundwater discharge areas that may need further attention during the interim remedial action or subsequent mitigation measures for the DRA.

The results of this investigation supplement and enhance existing surface water and sediment data collected during surface water and sediment investigations in Frog Mortar Creek in 1997 and 2004; the Phase I, Phase II, and Phase III investigations in 2007 and 2008; and the more recent annual surface-water monitoring program conducted from 2010–2015. This report is organized as follows:

Section 2— Site Background: Briefly describes the site history and previous investigations.

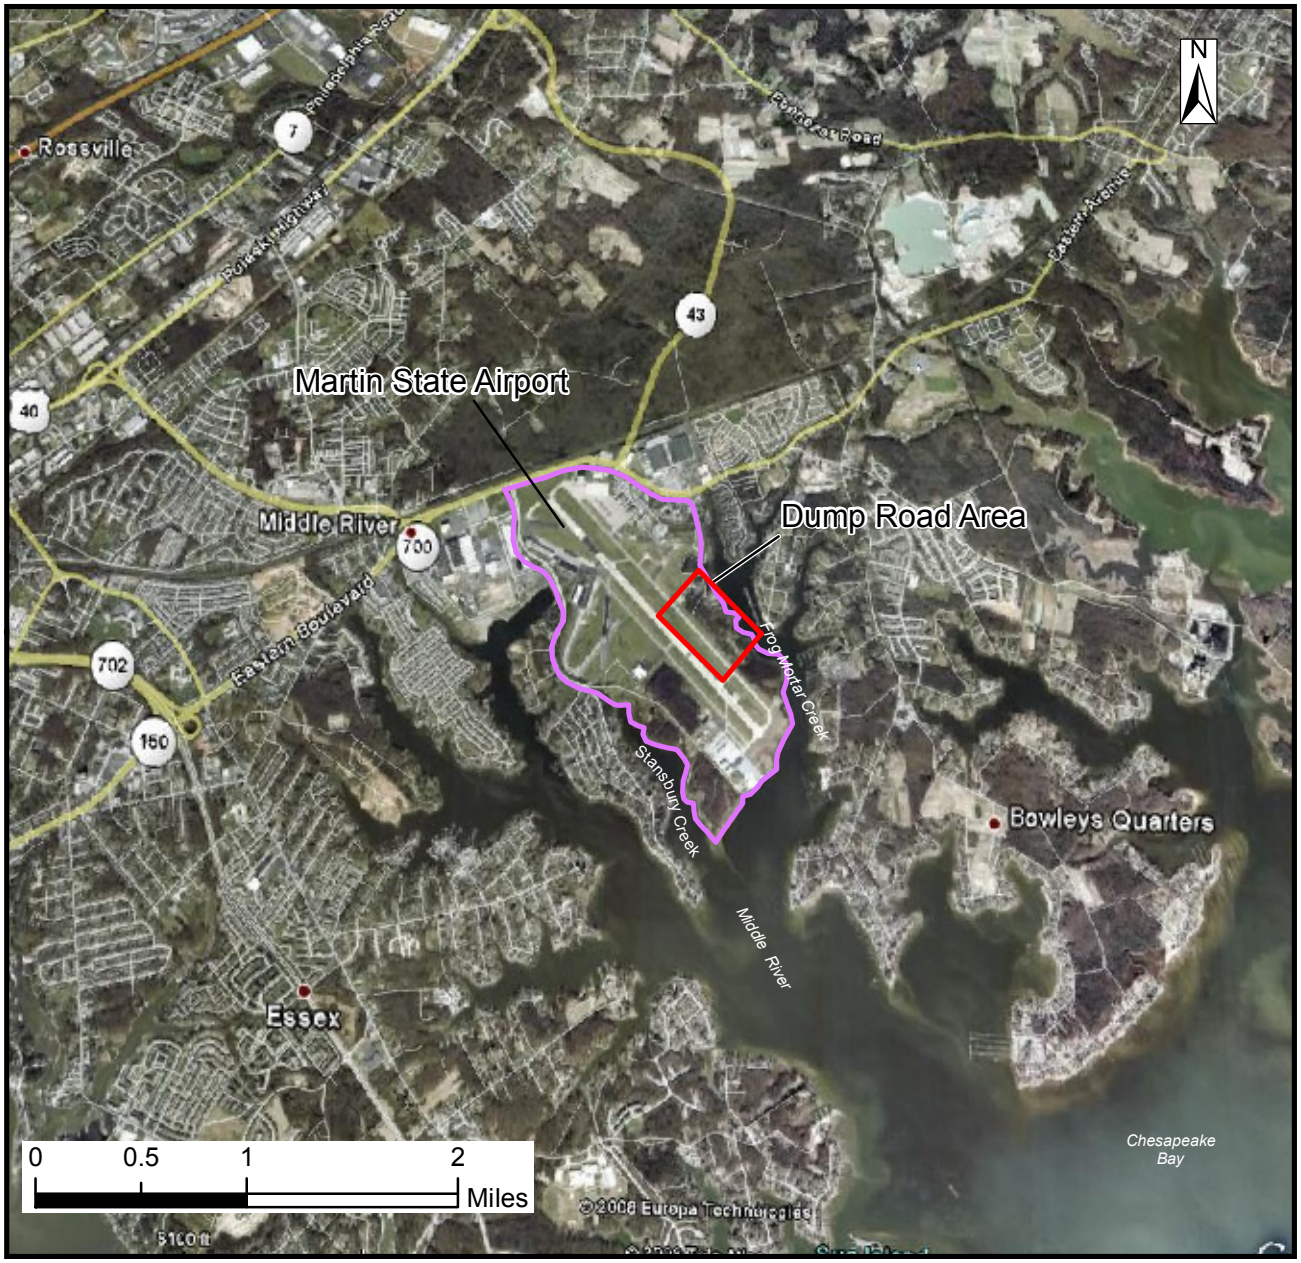

Section 3— Investigation Approach and Methodology: Presents the technical approach and the field and analytical methodologies used for this investigation.

Section 4— Results: Describes the results and major findings of the investigation.

Section 5— Summary: Summarizes the investigation program and its findings.

Section 6— References: Cites references used in compiling this report.

Section 2
Site Background

2.1 SITE DESCRIPTION

2.1.1 Location

Martin State Airport (MSA) is at 701 Wilson Point Road in Middle River, Maryland. It is bounded by Frog Mortar Creek to the east and Stansbury Creek to the west (Figure 2-1). Both creeks are tidal tributaries of Chesapeake Bay and join Middle River south of the airport. The Dump Road Area (DRA) is in the southeastern portion of MSA and is bounded by Frog Mortar Creek to the east and the airport runway to the west. This area has been investigated since the 1990s, and Lockheed Martin Corporation (Lockheed Martin) designated the site as the DRA to distinguish it from other MSA areas under investigation (e.g., Frog Mortar Creek, Strawberry Point, Greater Strawberry Point, and the Main Terminal area).

2.1.2 Surface Water Hydrology

Frog Mortar Creek and Stansbury Creek are wide, brackish, tidal tributaries of middle Chesapeake Bay. Surface water runoff from MSA enters these creeks via localized gullies in the undeveloped eastern and western portions of the site, or via storm sewers that drain the airport runway, taxiways, and developed portions of the facility. MSA encompasses 47 drainage areas in three watersheds, forming a total drainage area of 700 acres (Maryland Aviation Administration [MAA], 2008). The airport drainage areas range from seven to more than 170 acres.

Groundwater from the surficial aquifer discharges to Frog Mortar Creek. Lockheed Martin conducted a study in 2010 to continuously monitor groundwater levels at the DRA and off-site properties, and also surface-water levels at both sides of Frog Mortar Creek, to better understand groundwater and surface water interaction and to update the DRA groundwater model (Tetra Tech, 2011). Mean tidal flux in the Middle River, Maryland area is approximately 1.6 feet (National Oceanic and Atmospheric Administration, 2015). Groundwater levels in several off-site piezometers and DRA wells responded to changes in barometric pressure and tides. Changes in

atmospheric pressure can produce sizable fluctuations in groundwater measured in wells penetrating confined or semi-confined aquifers. The relationship is inverse; that is, increases in atmospheric pressure produce decreases in water levels, and decreases in atmospheric pressure produce rising water levels (Todd, 1980).

Daily variations of the lunar gravitational field also affect groundwater levels, as indicated by semi-diurnal "tidal" fluxes. Water in the well casings can be affected directly by the pressure flux, or indirectly via inflow of surface water from nearby surface water bodies during rising tides and by groundwater outflow to nearby surface water bodies during lowering tide. Surface water levels in Frog Mortar Creek also responded to fluctuations of barometric pressure and tides during the study.

The inflow of surface water into the aquifer and outflow of groundwater to a surface water body is typically localized near the shoreline, and is expected to only occur at great distances in high-permeability formation materials (i.e., gravels and coarse sand) or in open fractures or solution channels in weathered limestone formations (which are not present at this site). Results from the 2010 study indicated both positive vertical-hydraulic gradients (upward flow potential), and negative vertical-hydraulic gradients (downward flow potential) at the wells and piezometers studied. Average positive vertical-hydraulic gradients were found at off-site piezometers on the eastern shoreline of Frog Mortar Creek, indicating more overall upward potential for groundwater flow in this area.

Lockheed Martin conducted another study in 2011 to ascertain the effects of tide and sampling depths on contaminant concentrations in Frog Mortar Creek (Tetra Tech, 2012). The tidal phase relative to the time of collection appeared to have some influence on the volatile organic compound (VOC) concentrations detected, particularly in the samples collected 50 feet from the shore. In general, VOC concentrations in "B-series" samples (at a distance of 50 feet from the shore) were greater at low tide than at high tide, irrespective of sampling depth.

2.2 PREVIOUS INVESTIGATIONS

Detailed environmental studies have been conducted at the DRA since early 1991, when the MAA removed drums discovered near Taxiway Tango. In July 1991, four drums containing dried zinc-chromate paint were uncovered during installation of underground electric cables adjacent to Taxiway Tango. This discovery prompted MDE to order MAA to conduct additional studies of the

Taxiway Tango area. Early investigations from 1991–1996 initially identified four areas of concern known as the Taxiway Tango Median Anomaly Area, the Drum Area, two ponds (Pond 1 and Pond 2), and the Petroleum Hydrocarbon Area. Detailed discussions regarding subsequent investigations of known and possible source areas, and the chemical results of historical sampling, are in the *Dump Road Area Characterization of Possible Source Areas Report* (Tetra Tech, Inc. [Tetra Tech], 2013), and are not repeated herein.

The DRA is currently comprised of open meadows, mowed grass, and heavily wooded areas; however, the DRA also extends to the airport runway, and includes a portion of Taxiway Tango. Taxiway Tango is a concrete and asphalt taxiway currently used by the Maryland Air National Guard for military aircraft operations. The airport runway is used by the Maryland Air National Guard and by state-owned and private aircraft.

Previous environmental studies at MSA demonstrate that soil, pond sediment, and groundwater at the DRA have been impacted by volatile organic compounds (VOCs), semivolatile organic compounds, and metals resulting from prior dumping and backfilling. The primary constituents that have been detected in site groundwater at concentrations exceeding state groundwater standards are the chlorinated VOCs (cVOCs) trichloroethene (TCE), *cis*-1,2-dichloroethene (*cis*-1,2-DCE), vinyl chloride (VC); petroleum-related VOCs such as benzene, toluene, ethylbenzene, and xylenes; and several metals. The distributions of TCE, *cis*-1,2-DCE, and VC in the upper, intermediate, and lower surficial-aquifer zones of DRA groundwater are shown on Figures 2-2 through 2-4, respectively.

2.2.1 Surface Water

Frog Mortar Creek is hydraulically downgradient of the DRA, and directly receives groundwater discharging from the DRA. TCE, *cis*-1,2-DCE, VC, benzene, toluene, xylenes, and several metals have been detected in surface water samples collected from Frog Mortar Creek. Surface water samples have been collected from Frog Mortar Creek since 1997, and multiple rounds of samples have been collected annually since 2010. TCE is the most common VOC detected in Frog Mortar Creek surface water samples (detected in 100% of 2014 Frog Mortar Creek samples), and is the second most common VOC detected in DRA groundwater (*cis*-1,2-DCE is the most common VOC detected in DRA groundwater).

Figures 2-5 and 2-6 show recent surface-water sampling locations and distributions of TCE in Frog Mortar Creek for a summer month (July) and a winter month (December) in 2014. The higher concentrations of cVOCs are typically found along sampling transects nearest the DRA (e.g., transects SW-38, SW-40, and SW-41), and at sampling locations nearest the western shoreline (i.e., in "A" or "B" samples) along these transects. TCE concentrations in Frog Mortar Creek during the summer occasionally exceed a risk-based, site-specific, swimming criterion of 10 micrograms per liter (µg/L); this criterion was developed to assess possible risk to swimmers in Frog Mortar Creek (see Figure 2-5). However, TCE has been found to exceed the criterion more frequently in the cooler months (see Figure 2-6), when swimming and recreational activities in Frog Mortar Creek are not expected.

TCE also occasionally exceeds a higher ecological screening criterion (21 µg/L), primarily in the colder months. *cis*-1,2-DCE (not shown on Figure 2-5) has not exceeded any of its screening criteria. VC (also not shown on Figure 2-5) exceeds its swimming criterion (0.7 µg/L) more frequently than TCE, but rarely exceeds its higher United States Environmental Protection Agency (USEPA) ambient water quality criterion (AWQC) for the human consumption of organisms (24 µg/L). VC exceeds its swimming criterion more frequently in the colder months of the year. Additional details for Frog Mortar Creek studies conducted from 1997–2014, and details of the area's physical setting, land use, physiography, and surface and subsurface conditions (i.e., soils, hydrology, and geology) are in the *2014 Annual Surface Water Sampling Report for Frog Mortar Creek* (Tetra Tech, 2015), and are not repeated herein.

2.2.2 Sediment

Frog Mortar Creek sediment investigations to date have focused on areas east of the airport. Frog Mortar Creek investigations began with a Phase I investigation in March 2007 (Tetra Tech, 2007) and were completed with a Phase III investigation in October 2008 (Tetra Tech, 2008). The objective of these investigations was to evaluate possible off-site migration of contaminants from a portion of the MSA property to Frog Mortar Creek. The phased investigation included the following:

- Phase I—identification of locations where groundwater seeps into surface water, using a Trident™ probe (March 2007)
- Phase II—surface water and shallow sediment sampling (October–November 2007)

- Phase III—sampling of deeper sediment (July 2008)

The three-phase investigation was conducted in Frog Mortar Creek adjacent to the DRA. The Phase I objective was to identify possible groundwater discharge zones by distinguishing temperature and conductivity differences between surface water and groundwater, and to collect pore-water samples from selected areas. The Phase II objective was to characterize areas of groundwater seepage into the creek and obtain analytical data to quantify the presence or absence of contaminants in Frog Mortar Creek sediment that might be related to groundwater transport or soil erosion from the site. The Phase III objective was to sample deeper sediment in areas of concern that had been identified in the first two study phases. A secondary objective of the Phase III investigation was to provide "regional" data for chemical concentrations in Frog Mortar Creek sediment along the entire eastern side of the MSA property.

The Phase I study identified the likely presence of groundwater discharge at the southern end of the MSA groundwater plume. The Phase II investigation indicated that groundwater discharge had impacted surface water and sediment in Frog Mortar Creek areas east of the DRA. *cis*-1,2-DCE was detected in two samples (FMC-15 and FMC-16) adjacent to the filled area. No other VOCs were detected in the samples containing *cis*-1,2-DCE. FMC-15 and FMC-16 are within the approximate lateral boundary of the VOC-impacted groundwater plume.

The Phase III investigation confirmed the Phase II results. In general, cVOCs were detected more frequently adjacent to the DRA in the immediate area of the known groundwater contaminant plume and filled channel area. The highest numbers of VOCs were detected adjacent to the DRA at FMC-15 and FMC-16. Individual VOCs were detected at other locations, but only at very low frequencies (i.e., one in 50).

The maximum concentrations of *cis*-1,2-DCE (3,200 micrograms per kilogram [µg/kg]) and TCE (3,200 µg/kg) were detected in sample FMC-16C (from the 1–2 foot horizon), which is east of the DRA fill area and within the area of surface sediment concern previously reported in Phase II. This sampling horizon also contained 1,2,4-trichlorobenzene (75 µg/kg). The maximum concentrations of VC (32 µg/kg) and trans-1,2-dichloroethene (1.7 µg/kg) were detected in sample FMC-16B (0-1 foot horizon). *cis*-1,2-DCE (2,600 µg/kg), TCE (910 µg/kg), and 1,2,4-trichlorobenzene (330 µg/kg) were also detected in sample FMC-15C (1–2 foot horizon) east of the DRA, whereas only *cis*-1,2-DCE (590 µg/kg) was detected in the shallower 0–1 foot horizon of sampling location

FMC-15B. These results also indicate that metals and polycyclic aromatic hydrocarbons (PAH) are widespread in Frog Mortar Creek sediment, including upstream locations.

All three phases of the Frog Mortar Creek investigation corroborate the conclusion that contaminated groundwater from MSA sampling locations in known fill areas (and within the lateral boundaries of the groundwater plume) is discharging to surface water and sediment adjacent to and east of MSA. Sediment sampling results and analyses show that the highest concentrations of cVOCs associated with DRA groundwater were detected in creek sediment adjacent to the site. The highest concentrations of metals were typically found at background sediment locations and the highest PAH concentrations were found in Gar Gut sediment.

Section 3
Investigation Approach and Methodology

This investigation sought to identify discernible differences in groundwater discharge to Frog Mortar Creek by using passive flux-meters (PFMs) and water-level measurements, and, to the extent possible, quantify water and contaminant-mass flux. PFMs were deployed in the shallow sediment of Frog Mortar Creek and left in place for two weeks. The PFMs were retrieved and sent to the University of Florida (Gainesville, Florida) for chemical analyses. University of Florida also interpreted the data, which included quantitation of groundwater flux and estimation of seepage flux rates. Water level data were also collected above and below the creek sediment and from three Dump Road Area (DRA) groundwater monitoring wells near Frog Mortar Creek, to evaluate groundwater and creek hydraulics during PFM deployment.

The activities for this investigation included:

- obtaining utility clearances from the Maryland "Miss Utility" clearinghouse
- mobilizing/demobilizing staff and equipment
- deploying/retrieving six PFMs during an initial application study
- deploying/retrieving 48 PFMs (in a grid arrangement) and four deep PFMs during the full-scale study
- deploying/retrieving electronic data loggers above and below creek sediment, and at three DRA groundwater monitoring wells, to record water levels
- analyzing the PFMs at the University of Florida laboratory for volatile organic compounds (VOCs) and indicator tracer-chemicals (used to estimate groundwater flux)
- evaluating water-level and environmental sampling data
- reporting results

3.1 UTILITY LOCATING

Field activities were coordinated with Lockheed Martin Corporation (Lockheed Martin) and Martin State Airport (MSA). Utility clearance work and documentation conformed to the provisions of Lockheed Martin's *Remediation Contractor's EESH Handbook* (Lockheed Martin, 2009a). Before installing the PFMs, Tetra Tech, Inc. (Tetra Tech) obtained a written clearance for underground utility locations from Maryland "Miss Utility" (as required by Maryland law) and reviewed site utility maps. A private utility-locating service was not used to locate and mark utilities for this project because the PFM sampling locations were beneath Frog Mortar Creek. Likewise, a Lockheed Martin digging permit and the standard MSA/Maryland Aviation Administration (MAA) digging permits were not required, because the sampling locations were not on Lockheed Martin and MSA/MAA properties.

3.2 MOBILIZATION/DEMOBILIZATION

Tetra Tech coordinated with the project subcontractors and mobilized personnel and materials to the field. Mobilization included locating the appropriate equipment required for field tasks, purchasing and leasing necessary equipment, and staging equipment for efficient loading and transportation to the site. Separate mobilizations were required to install and retrieve the PFMs (for both initial and full-scale deployments). Mobilization also included the following activities:

- mobilizing subcontractors, equipment, and materials to the site
- implementing the following:
    - site-specific health and safety plan
    - emergency response plan
    - sampling and analysis plan
    - waste management plan conforming to Lockheed Martin's *Energy, Environment, Safety, and Health (EESH) Remediation Waste Management Procedure No: EROP-03, Revision 4* (effective April 17, 2009) [Lockheed Martin. 2009b]
    - quality assurance/quality control (QA/QC) plan
    - data management plan

Demobilization included the following activities:

- demobilizing equipment and materials from the site at work completion
- performing general site cleanup and removing trash

3.3 PASSIVE FLUX-METER INVESTIGATIONS

Dr. Michael Annable (University of Florida) originally developed the PFM for placement within the screened interval of groundwater monitoring wells, where it is used to measure contaminant flux in groundwater at hazardous waste sites. In that application, the PFM is designed to quantify the horizontal flow of groundwater and identify zones with the highest contaminant flux. PFMs have been used successfully in several studies, and the applications and results of these studies are documented in peer-reviewed journals (see references in Appendix A). For the Frog Mortar Creek application, Dr. Annable modified the PFM design to quantify water and contaminant exchange at the sediment and surface water interface.

The PFM consists of a flexible, permeable membrane capable of adsorbing/retaining chemical constituents via its internal media (i.e., sorbent). The PFM membrane contains granular activated-carbon (GAC) that adsorbs VOCs (and other constituents) in groundwater as it flows through the PFM. The GAC is impregnated with five alcohol tracers that have different partitioning characteristics. The tracers are leached from the PFM at rates proportional to the rate of groundwater flow through the PFM.

For this study, PFMs were inserted into small, two-foot drive-point devices (i.e., mini-wells) constructed of two-inch-diameter polyvinyl chloride (PVC) solid casing with a PVC slotted-screen. The top of the drive-point device was closed using a threaded end-cap. The bottom of the drive-point device was closed with a conical end-cap to aid drive-point advancement into creek sediment. Devices were advanced using a slide hammer. PVC screen-sections at the upper and lower portions of the device allowed water to enter and exit. The PFM device and its installation method are shown on Figure 3-1.

As groundwater flows through the PFM, VOCs are adsorbed by the GAC and the alcohol tracers are leached from the device. The mass of VOCs accumulated in each PFM, and the mass of each tracer remaining on each PFM, were measured at the University of Florida laboratory. The loss of tracers is directly related to groundwater flow velocity and the duration of the PFM deployment period. Upward and downward flow in the PFM is estimated by measuring the mass of tracer remaining above or below the center section of the PFM. The combination of these analyses is designed to provide spatial data for groundwater flux and contaminant-mass flux per unit area

(i.e., per square meter). Additional construction details for the PFM and the chemical analyses performed on them are in the University of Florida report (Appendix A).

3.3.1 Initial Passive Flux-Meter Investigation

Tetra Tech initially deployed six PFMs (PFM-1 through PFM-6) along a transect extending from the DRA shoreline toward the center of Frog Mortar Creek, as shown on Figure 3-2. The objectives of the initial deployment were to: (1) evaluate the logistics of deployment, tethering, and retrieval; (2) evaluate PFM design, analytical procedures, and analyte detection limits; and (3) identify factors at the site that could influence PFM deployment during the full-scale study. The six initial PFMs were installed along a transect placed between surface water sampling transects SW-38 and SW-40, at the location where the highest VOC concentrations are typically detected during quarterly and summer-month sampling events.

The PFM transect is hydraulically downgradient of high VOC concentrations in DRA groundwater, as indicated by data for wells MW-52S/I/D (see Figures 2-3 and 2-4 in Section 2), groundwater-elevation contouring (Tetra Tech, 2013), and three-dimensional groundwater modeling (Tetra Tech, 2014). This transect is also downgradient of the former Limehouse Cove location, where the presence of backfill material may provide preferential movement of groundwater to Frog Mortar Creek. PFM-1 was installed approximately 10 feet outward from the low-tide line along the shoreline; PFM-2 through PFM-6 were spaced approximately every 50 feet toward the center of Frog Mortar Creek.

Initial deployment and retrieval were completed using a pontoon-configured boat. This provided the appropriate stabilization needed to deploy and retrieve the PFMs. PFMs were installed via slide hammer into sediment at approximately two-foot depths. Sampling locations were surveyed using a hand-held global positioning system (GPS) with sub-meter accuracy in Maryland State Plane North American Datum of 1983 (NAD83). A retrieval string and small float were attached to each PFM. Tide stage at the time of the survey was recorded and the depth to the top of the surface-water/sediment interface was measured using a weighted tape. The PFMs were retrieved two weeks later (May 13–14, 2014) by divers, and were packaged and shipped to the University of Florida laboratory for chemical analysis.

3.3.2 Full-Scale Passive Flux-Meter Investigation

As shown on Figure 3-3, 48 PFMs (PFM-07 through PFM-54) were deployed in a grid arrangement along 12 transects in Frog Mortar Creek during the full-scale study. PFMs were installed two feet below the creek sediment/surface water interface at four locations along 11 transects (as indicated by the green and black dots in Figure 3-3). PFMs were spaced every 50 feet at distances of 10, 60, 110, and 160 feet from the western shoreline. Four deep PFMs (DPFM-51 through DPFM-54) were installed at a depth of four feet along the twelfth transect (near the center of the study area), in an area where higher VOC concentrations have been detected in Frog Mortar Creek surface water samples. The PFMs were installed on March 25–26, 2015 and were retrieved after approximately two weeks on April 7–8, 2015.

The PFMs were installed using a slide hammer. PFM locations were surveyed via a handheld GPS with sub-meter accuracy, using the Maryland State Plane NAD83. Retrieval locations were identified via GPS and by a chain and small float attached to each PFM, although most of the floats were found missing upon retrieval of the PFMs. Forty-four of 48 PFMs were retrieved; four PFMs (PFM-11, PFM-12, PFM-28, and PFM-41) could not be located and were not recovered. PFMs were then packaged and shipped to the University of Florida laboratory for chemical analyses.

Water levels were recorded using electronic pressure-transducers/data-loggers in creek sediment near DPFM-52, in Frog Mortar Creek at 3300 Edwards Lane, and in three DRA groundwater monitoring wells (MW-48S, MW-48I, and MW-48D) (see Figure 3-3). Near DPFM-52, two data loggers were used to record water levels at two depths (2.5 and 4.5 feet) in sediment beneath the creek bed. Additionally, a barometric pressure data-logger was placed into the annular space of well MW-48S to record atmospheric barometric pressure during the monitoring period.

The barometric pressure logger was placed between the well casing and the vented, protective steel outer-casing of the well. Barometric pressure measurements were required because the data loggers installed into creek sediment were not vented to the atmosphere. Sediment PFM readings were corrected for barometric pressure to provide accurate readings of water pressure (i.e., pressure due to water depth only) and water elevations.

The internal clock of each logger was synchronized to Eastern Standard Time obtained from the National Institute of Standards and Technology time website (http://www.time.gov). Loggers simultaneously recorded and stored water-level measurements every five minutes (e.g., 12:00,

12:05, 12:10, 12:15, etc.). The five-minute recording interval was selected because it is sufficiently short to capture the shape of tidal and other short-term fluctuations in water levels, but not so frequent as to fill the data loggers' computer memory. Before data loggers were started, the initial "depth to water" level of surface water or groundwater was measured manually using an electronic water-level meter graduated to 0.01 feet. Water levels were measured from the top of each well casing or standpipe. Pre-monitoring water-level data for each location was used to set the data logger reference-level for the monitoring period. After the data were downloaded, the depth-to-water readings were converted to report water elevations in feet, in accordance with the North American Vertical Datum of 1988 (NAVD88). Water level data are in Appendix B.

The depth of water for the two pressure transducers/data loggers installed in sediment was 52 inches (4.33 feet) at installation (at approximately 11:45AM on March 25, 2015). The water elevation of Frog Mortar Creek at that time was 0.080 feet above NAVD88 (based on the creek gaging location at 3300 Edwards Lane). Therefore, the approximate elevation of the creek bed in the study area is estimated at approximately 4.25 feet below NAVD88 (-4.25). The approximate elevations of the two pressure transducers/data loggers installed in sediment were 6.75 feet below NAVD88 (-6.75) and 8.75 feet below NAVD88 (-8.75).

3.4 LABORATORY ANALYSIS

The PFMs were analyzed for VOCs and alcohol tracers at the University of Florida laboratory under the supervision of Dr. Michael Annable. The methods used for the chemical analyses are standard, industry-accepted and -approved methods. During analysis, a GAC sample from each PFM was homogenized by mixing. Approximately 10 grams of GAC were then transferred into pre-weighed 40-milliliter vials that were subsequently filled with 30 milliliters of methylene chloride (the extraction solvent). The vials were rotated at a slow speed (20% or less rotation speed) for 24 hours, and then refrigerated for 24 hours or more to allow suspended particulate matter to settle out. The supernatant was sub-sampled using two-milliliter gas-chromatogram vials. If needed, a syringe filter (Cameo 17F syringe filter, Teflon, 0.22 micron) was used to filter the particulate in suspension. The supernatant was analyzed for alcohol tracers by a gas chromatogram equipped with a flame-ionization-detector.

3.5 DOCUMENTATION

A master site logbook was maintained as an overall record of field activities for the site. Sample documentation included completed chain of custody forms and matrix-specific sample log sheets. The chain of custody forms are standardized to summarize and document pertinent sample information, such as sample identification, type, matrix, date and time of collection, preservation, and requested analysis. Sample custody procedures are designed to document sample acquisition and integrity.

3.6 SAMPLE NOMENCLATURE AND HANDLING

PFMs submitted to the University of Florida laboratory were labeled with a "PFM" or "DPFM" prefix, identifying the sampled medium as a passive flux-meter or deep passive-flux-meter, respectively, followed by a two-digit numeral to identify the sampling location. For example, PFM-10 designates a PFM sample collected at location 10. Sample handling includes field-related considerations concerning the selection of sample containers, preservatives, allowable holding times, and chemical analyses.

Proper custody procedures were followed throughout all phases of sample collection and handling. Pre-investigation PFMs were released under signature from the laboratory and were accepted under signature at delivery by Tetra Tech. Transport containers for PFMs were sealed with strapping tape and a custody seal. The custody seal contained the signature of the individual releasing the transport container, along with the date and time. These protocols demonstrate that the PFMs were handled and transferred in a manner that would prevent tampering.

Section 4
Results

The following sections discuss the results of the full-scale passive flux-meter (PFM) and water level studies. The discussion on the PFM study includes assessments related to groundwater discharge to surface water, contaminant-mass discharge, and total-mass discharge to Frog Mortar Creek. The discussion of the water level results relates the groundwater and surface-water elevation data with respect to changes in barometric pressure, tides, location, and data-logger depth.

4.1 PASSIVE FLUX-METER INVESTIGATION

The distribution of net specific-water discharge for the full-scale PFM investigation (PFM-7 through PFM-54) is shown on Figure 4-1. Net fluxes for the volatile organic compounds (VOCs) trichloroethene (TCE), 1,2-dichloroethene (1,2-DCE), and vinyl chloride (VC) are shown on Figure 4-2. TCE, 1,2-DCE, and VC were selected for this study because they are the most common chlorinated VOCs (cVOCs) detected in Frog Mortar Creek surface-water samples and Dump Road Area (DRA) groundwater samples, and because they pose the greatest risk to human and ecological receptors in Frog Mortar Creek.

Table 4-1 lists the net-specific discharge of water (Figure 4-1) and the net mass-flux results for TCE, 1,2-DCE, and VC (Figure 4-2). Net-specific discharge (Figure 4-1) is the sum of total upward and downward water flow, as estimated by the evaluation of flow tracers placed in the PFMs. A positive net-flow rate indicates upward flow of groundwater is greater than downward movement of surface water during the study period, and thus a greater net discharge of DRA groundwater to Frog Mortar Creek. A negative net flow rate indicates downward flow of surface water to the sediment is greater than upward groundwater flow during the study period.

4.1.1 PFM Groundwater Flow

Table 4-1 and Figure 4-1 show the net discharge rates for groundwater, as determined by the PFM study. The findings listed below are based on Table 4-1, Figure 4-1, and the mass-flux measurement report (Appendix A):

- The average groundwater flow over the PFM sampling area is 6.7 centimeters per day (cm/day) (i.e., 0.22 foot per day [ft/day]), indicating an overall upward groundwater flow for the study area. Net water-flow rates range from a maximum of 38.3 cm/day (1.26 ft/day) at PFM-31 to a minimum of -17.2 cm/day (-0.56 ft/day) at PFM-17.

- A contiguous area of relatively high upward flow is indicated in the southern portion of the DRA near PFM-31 (maximum positive flow location), with higher positive flow rates also nearby at PFM-35 (37.4 cm/day), PFM-32 (28.6 cm/day), and, to a lesser extent, at PFM-36 (14.7 cm/day), PFM-37 (16.7 cm/day), and PFM-39 (17.1 cm/day).

- Net upward groundwater flow occurs at all shoreline PFM locations, except for PFM-23 (another shoreline location, PFM-11, could not be evaluated because the PFM was not recovered). This indicates that groundwater generally discharges to Frog Mortar Creek at the near-shore locations, whereas offshore locations show occasional surface water recharge to groundwater.

- Predominant net upward groundwater flow occurs in several northernmost and southernmost transects.

- Predominant net downward flow occurs in central transects near former Limehouse Cove (PFM-19 though PFM-26, and PFM-51 through PFM-54).

- Net upward flow increases away from the shoreline in the two northernmost transects (PFM-07 through PFM-10; and PFM-13 and PFM-14).

- An area of relatively high net upward groundwater flow occurs at the shoreline in the center of the study area (DPFM-51 and PFM-19), with decreasing upward flow and/or net downward flow farther from shore.

- The moderate net upward flow at DPFM-51 (13.5 cm/day [0.44 ft/day]) may partially explain frequent VOC maximums in near-shore Frog Mortar Creek surface-water samples collected from location SW-38A.

4.1.2 PFM Mass-Discharge Flux

Table 4-1 and Figure 4-2 show the net mass-discharge fluxes for TCE, 1,2-DCE, and VC, as determined by the PFM study. Locations PFM-15, PFM-16, and PFM-31 account for most of the VOC mass discharge. These three PFM locations, along with the other PFMs within the two transects in which they occur, account for 96% of the total VOC-mass discharge to Frog Mortar Creek within the study area (Appendix A). PFM-15 and PFM-16 are in the northern portion of the study area, northeast of wells MW-47S/I/D (with TCE concentrations ranging from 380-3,800 micrograms per liter [µg/L] in 2015), and near surface-water sampling locations SW-40A and SW-40B (with TCE concentrations ranging from 2.1–24 µg/L in 2015). PFM-31 is hydraulically downgradient of wells DMW-4S/I/D and MW-49S/I/D (with TCE concentrations

ranging from 500–9,000 µg/L in 2015), and south of surface water sampling location SW-48A (with a relatively high TCE concentration of 24 µg/L in July 2015).

The study indicates a total VOC-mass discharge of 2,900 grams per day (g/day) over approximately seven acres. However, the mass discharge estimate may be significantly lower if adjusted for flow convergence that might possibly occur in the PFMs. One flow-convergence scenario indicates that the calculated-mass discharge could be reduced by a factor of approximately 30, which would adjust the total VOC-mass discharge to 100 g/day (see Appendix A). That particular flow-convergence scenario assumes a sediment hydraulic-conductivity of three meters per day (9.84 ft/day), which is a typical value for clean sand or silty sand (Freeze and Cherry, 1979), and 100 times lower than the permeability of the GAC sorbent used in the PFMs.

Site-specific information is required regarding sediment hydraulic-conductivity and anisotropy[1] to more accurately estimate the flow-convergence adjustment. The convergence-adjusted PFM VOC-mass discharge estimate of 100 g/day to Frog Mortar Creek is higher than the VOC-mass discharge estimate of 4 g/day provided by three-dimensional, solute-transport model simulations conducted for the DRA (Tetra Tech, 2014). However, the convergence-adjusted VOC discharge rate of 100 g/day is more in line than the unadjusted estimated VOC discharge rate to Frog Mortar Creek of 2,900 g/day.

Other locations with elevated VOC net-mass-discharge rates are DPFM-51/PFM-23, PFM-22, and PFM-27. DPFM-51/PFM-23, and PFM-27, near the shoreline in the central portion of the DRA. They are hydraulically downgradient of wells DMW-2A/B and MW-48S/I/D (with TCE concentrations ranging from 170–5,800 µg/L in 2015), and near surface water sampling locations SW-38A and SW-48A (with TCE concentrations ranging from 3–28 µg/L in 2015). PFM-07 and PFM-08, in the northern portion of the study area, are downgradient from the Maryland Air National Guard armory and have the lowest of the elevated (> 0.001 g/day) mass-discharge rates.

The locations with the highest VOC net-mass-discharge rates were not always associated with the highest net upward groundwater flow rates. The first and third highest VOC discharge rates detected at PFM-15 and PFM-16 have upward groundwater flow rates that are only slightly more than half the maximum groundwater flow (22.9 cm/day and 24.3 cm/day, respectively, as compared to 38.3 cm/day). PFM-14 had one of the highest upward groundwater flow rates

[1]Having unequal physical properties along different axes.

(30.2 cm/day), yet no VOC flux was detected at that location. PFM-22 and PFM-23 had a low upward and a downward flow rate, respectively, but only moderate VOC fluxes were detected at these two locations. This indicates that uncontaminated groundwater might be discharging in these areas. This should be considered when optimizing the groundwater interim remedial action.

4.2 WATER LEVELS

Hydrographs of the recorded Frog Mortar Creek elevations, groundwater elevations, and barometric pressure are shown on Figure 4-3. Surface water levels in Frog Mortar Creek respond to tides and fluctuations in barometric pressure. Groundwater levels measured in the three wells used in this study also fluctuated in response to tides and barometric pressure, but at lower amplitudes as compared to Frog Mortar Creek.

Groundwater responses to tides and barometric pressure for the intermediate and deep wells (MW-48I and MW-48D) were greater than the shallow well (MW-48S), which is likely related to the greater storativity in the unsaturated vadose zone, and possibly a lower permeability of the geologic formation at MW-48S. In a water table aquifer, primary storage spaces just above the water table can fill and drain readily. In the intermediate and deep zones, tidal fluctuations likely diminish less rapidly with distance from Frog Mortar Creek, because the condition of these zones is semi-confined or confined. Under these semi-confined conditions, much less damping of the tidal signal occurs, because the aquifer units are fully confined and under artesian pressure.

Throughout most of the monitoring period, barometric pressure fluctuated regularly between 33.50 and 34.48 feet of water (34 feet of water is equivalent to 30.01 inches of mercury). Generally, water levels for Frog Mortar Creek ranged from slightly above North American Vertical Datum of 1988 (NAVD88) to one foot below NAVD88 (average of 0.66 foot below NAVD88). More extreme tidal fluxes were observed for Frog Mortar Creek on the morning of March 29, 2015 (with a low elevation of 2.259 feet below NAVD88 at 9:10), the afternoon of March 30, 2015 (with a maximum elevation for the monitoring period of 0.982 feet above NAVD88 at 14:55), and the afternoon of April 4, 2015 (with a minimum elevation for the monitoring period of 2.642 feet below NAVD88 at 16:00).

Similar minimum and maximum elevation events also occurred for groundwater (i.e., wells MW-48S/I/D) during these periods. The lunar cycle for the study period consisted of the first-quarter moon on March 27, 2015, a full moon on April 4, 2015, and the third-quarter moon

on April 11, 2015. Therefore, progressively larger lunar tides were expected to occur approaching April 4, 2015 (i.e., full moon), and progressively smaller lunar tides were expected approaching April 11, 2015 (i.e., third quarter moon). The most extreme water elevations occurred near or on the full moon date of April 4, 2015, but they were enhanced by rapid and extreme barometric pressure variations.

The groundwater data indicate higher groundwater elevations for the intermediate and deep surficial-aquifer wells (MW-48I and MW-48D) as compared to the shallow surficial-aquifer well (MW-48S). The greater intermediate- and deep-aquifer groundwater elevations suggest upward hydraulic-gradients near the edge of the DRA during most of the monitoring period, which indicates upward groundwater flow potential from the deeper portions of the surficial aquifer to the shallower portions of the surficial aquifer. Groundwater hydraulic gradients at MW-48S/I/D appear to be downward during periods of increasing barometric pressure (e.g., March 29 and April 4–5), where intermediate and deeper groundwater levels (in wells MW-48I and MW-48D) are lower than those in the upper surficial aquifer (well MW-48S).

The pressure transducers/data loggers installed in Frog Mortar Creek sediment were unvented; therefore, readings for these instruments reflect the total pressure of the water above the transducer and the air pressure above the water surface (i.e., barometric pressure). Subtracting the barometric pressures from the sediment pressure readings provides the pressure for the water above the loggers only (i.e., total hydraulic pressure). Total hydraulic pressure was adjusted for the elevation of each logger, and the hydraulic gradient for each measurement was computed using a distance of two feet between the two pressure transducers/data loggers in the sediment.

Figure 4-4 shows time-series plots of water elevations and hydraulic gradients for the pressure transducers/data loggers installed in sediment. For most of the study period, the static water elevation of the deeper unit was greater than the elevation in the shallow unit (lower plots), indicating upward water flow from the deeper portion of the sediment to the shallower portion of the sediment (and subsequently the creek). Upward flow is indicated by an average hydraulic gradient of 0.246 foot per foot. This value agrees with the results from the water-flow tracer analyses conducted during the PFM study (see Appendix A).

The blue horizontal line shown in the upper plot area of Figure 4-4 represents a zero hydraulic gradient (the equalization point representing no flow potential). Hydraulic gradients plotted below

this line indicate downward flow (from the upper portion of the sediment to the lower portion of the sediment). Downward hydraulic gradients occurred regularly after March 30, 2015 until the end of the monitoring period on April 7, 2015, and predominantly coincided with the highest portions of the tide cycles (i.e., when water was deepest in Frog Mortar Creek). The downward vertical gradients appear to be more frequent during periods of relatively stable barometric pressure, or when a short rapid drop in barometric pressure coincided with a rising tide.

Summary

In 2014–2015, Tetra Tech, Inc. (Tetra Tech) conducted a groundwater characterization study on behalf of Lockheed Martin Corporation (Lockheed Martin) at Frog Mortar Creek and the Dump Road Area (DRA) of Martin State Airport (MSA), in Middle River, Maryland. The investigation further characterized the distribution and discharge of contaminated groundwater emanating from the Dump Road Area to Frog Mortar Creek. The results will be used to update the Dump Road Area groundwater model to improve its accuracy and to optimize pumping rates for the interim remedial action. The study deployed and retrieved water-level data-loggers, and included the deployment, retrieval, and chemical analyses of passive flux-meters (PFMs) installed in the sediment of Frog Mortar Creek. This investigation was conducted in conjunction with the University of Florida.

The passive flux-meter, developed by Dr. Michael Annable of the University of Florida, measures contaminant flux in groundwater at hazardous waste sites. The passive flux-meter was modified for this study to quantify water and contaminant exchange at the sediment and surface water interface. The passive flux-meter consists of a flexible, water-permeable membrane capable of adsorbing/retaining volatile organic compounds (VOCs) via its internal sorbent medium (granular activated-carbon [GAC]). The membrane is impregnated with five alcohol tracers that have different partitioning characteristics. Tracer lost is directly related to water flow velocity and to the duration of the passive flux-meter deployment period. Passive flux-meters were inserted into small, two-foot-long drive-point devices (i.e., mini-wells), constructed of a two-inch-diameter polyvinyl chloride (PVC) solid casing with a slotted screen. The mini-wells were advanced into the sediment using a slide hammer.

Tetra Tech, Inc. initially deployed six passive flux-meters in May 2014 along a transect extending from the shoreline of the Dump Road Area towards the center of Frog Mortar Creek. This initial deployment was used to evaluate parameters needed to conduct a full-scale passive flux-meter

study over a larger area of Frog Mortar Creek. For the full-scale study, Tetra Tech, Inc. deployed 48 passive flux-meters on March 25–26, 2015.

Passive flux-meters were arranged in a grid along 11 transects two feet below the sediment in Frog Mortar Creek, at distances of 10, 60, 110, and 160 feet from the western shoreline. Four deeper passive-flux-meters (four feet deep) were also installed parallel to one transect near the center of the Dump Road Area, in an area with historically high concentrations of chlorinated volatile organic compounds (i.e., trichloroethene [TCE], *cis*-1,2-dichloroethene [*cis*-1,2-DCE], and vinyl chloride [VC]). The passive flux-meters were left in the sediment for approximately two weeks and were retrieved on April 7–8, 2015.

Four devices could not be located and were not recovered. The recovered devices were analyzed by the University of Florida for volatile organic compounds and for the alcohol tracers that are used to estimate the direction and magnitude of water flow through the device. Electronic water-level pressure-transducers/data-loggers were used to record water levels at two depths in creek sediment in the Frog Mortar Creek study area, and also in three Dump Road Area groundwater-monitoring wells, to evaluate groundwater and surface water flow interaction and to study contaminant flux to Frog Mortar Creek from groundwater at the Dump Road Area.

A contiguous area of relatively high upward flow is indicated in the southern portion of the DRA near PFM-31 (maximum upward flow location), with higher upward flow rates also at nearby PFM-35 and PFM-32, and, to a lesser extent, at PFM-36, PFM-37, and PFM-39. Locations PFM-15, PFM-16, and PFM-31 account for most of the estimated-mass discharge of volatile organic compounds to the creek. These three locations, and the other passive flux-meters within the two transects in which they occur, account for 96% of the total mass of volatile organic compounds discharged to Frog Mortar Creek in the study area. PFM-15 and PFM-16 are in the northern portion of the study area, northeast of wells MW-47S/I/D (with trichloroethene concentrations ranging from 380–3,800 micrograms per liter [µg/L] in 2015), and near surface water sampling locations SW-40A and SW-40B (with trichloroethene concentrations ranging from 2.1–24 µg/L in 2015). PFM-31 is hydraulically downgradient of wells DMW-4S/I/D and MW-49S/I/D (with trichloroethene concentrations ranging from 500–9,000 µg/L in 2015), and south of surface water sampling location SW-48A (with a relatively high trichloroethene concentration of 24 µg/L in July 2015).

This study indicates an estimated total-mass discharge of 2,900 grams of volatile organic compounds per day to approximately seven acres of Frog Mortar Creek. However, this passive flux-meter mass-discharge estimate of 2,900 grams per day to Frog Mortar Creek and the lower mass-discharge estimate of 100 grams per day to Frog Mortar Creek (adjusted for flow convergence) are higher than the volatile organic compound-mass discharge estimate of four grams per day provided by three-dimensional, solute-transport model simulations conducted for the Dump Road Area (Tetra Tech, 2014). Site-specific information for sediment hydraulic-conductivity and anisotropy is required to more accurately estimate the flow-convergence adjustment for mass discharge to Frog Mortar Creek.

Water levels in shallow creek sediment, Dump Road Area groundwater, and Frog Mortar Creek responded to lunar tides and variations in barometric pressure. During most of the study period, static water-elevations for loggers installed in deeper sediment were greater than the levels for loggers installed at shallower depths, indicating upward water flow (i.e., from the deeper to shallower portions of the sediment). The predominant upward flow of groundwater to Frog Mortar Creek indicated by the water level measurements agrees with the results of the passive flux-meter study that also indicate overall upward flow. However, note that the passive flux-meter study also indicates predominantly downward water flow in some areas of the creek.

Introduction

The Frog Mortar Creek site located near the Martin State Airport is a tidally influenced surface water body that has received input of volatile organic compounds through groundwater discharge emanating from the nearby Dump Road Site. The mass flux and mass discharge from groundwater to the surface water is the focus of the monitoring activity described in this report. The conceptual model of organic compounds travelling from a source area through the aquifer and discharging to surface water was investigated using passive advective sampling devices called Sediment Bed Passive Flux Meters (SBPFMs). The application of the SBPFM in the sediments along the shoreline of Frog Mortar Creeks with provide data to improve the conceptual site model and provide a quantitative assessment of the flux and mass discharge of chlorinated solvent compounds to surface water. This information can be used to improve remedial designs and as a baseline for later comparison following remedial efforts.

The SBPFM enables a local site-specific measurement of contaminant and water fluxes to improve on Conceptual Site Models and provide information on the spatial mass flux distribution through the sediments. The SBPFM design is based on the previously developed passive flux meter (PFM) designed by the University of Florida (Hatfield et al., 2004; Annable et al., 2005). The SBPFM is a self-contained permeable unit constructed as a drive point inserted into the sediment so that it intercepts vertical flow of groundwater through intake and exhaust screens. The interior composition of the SBPFM is a matrix of hydrophobic and/or hydrophilic permeable sorbents that retain dissolved organic and inorganic contaminants present in fluid intercepted by the SBPFM. The sorbent matrix is also impregnated with known amounts of one or more fluid soluble resident tracers. These tracers are leached from the sorbent at rates proportional to water flux.

After a period of exposure to groundwater flow in the sediments, typically one to two weeks, the SBPFM drive point is removed from the sediment bed. Following removal, the sorbent matrix contained within the SBPFM is removed, segmented, homogenized and sub-sampled. The samples are then extracted and analyzed to quantify the mass of all contaminants intercepted by the SBPFM and the residual resident tracers within vertical segments of the SBPFM. The contaminant masses are used to calculate cumulative and time-averaged contaminant mass fluxes, while the remaining residual tracer masses are used to calculate cumulative or time-average water flux.

Deploying an array of SBPFMs along a shoreline or in transect perpendicular to the shoreline provides information on the distribution of mass flux and water flux between a contaminant plume migrating from the aquifer, through the sediments and into surface water. This information can be used to quantify the total mass discharge of contaminants to surface water and provide quantitative targets for remedial strategies. In addition, the spatial distribution of contaminant flux can provide information on where remedial efforts should be targeted in an effort to reduce mass discharge to surface water. Finally,

the SBPFM provides quantitative information that can serve as a baseline for evaluating the performance of remedial methods implemented.

Methods and Procedures

At the Frog Mortar Creek site, SBPFMs were used to measure water and contaminant mass flux vertically through sediments in the creek bed. Flux refers to the mass of water and or contaminants flowing per unit area at a measured point in a well screen averaged over a given period of time. Based upon this general definition, the units associated with mass flux are determined as:

$$flux = \frac{mass}{area \cdot time} = \left[\frac{M}{L^2 T}\right]$$

where the terms M, L, and T represent the base units of mass, length, and time respectively. For consistency with common practice, the ambient groundwater flux will be discussed in terms of the specific discharge or Darcy velocity, which is the volumetric water flux (or flow rate) through a specified cross-sectional area. The resulting units are L/T and for this report the Darcy velocity will be represented with the units of cm/day. For this report the contaminant flux will be discussed in terms of mass flux ($M/(L^2T)$) and represented with the units of ($mg/m^2/day$).

In order to determine the rate of vertical water flow through the SBPFM, a suite of four tracers was equilibrated on the activated carbon (methanol, ethanol, isopropyl-alcohol, tertiary butyl-alcohol and 2,4 dimethyl-3-pentanol, at concentrations of 1 to 3 mg/g). Following deployment of the SBPFMs, the fraction of each tracer remaining on the activated carbon, M_R, was used to calculate the specific discharge through the SBPFM, q, using:

$$q = L\theta R_d (1-M_R)]/t$$

where; L is the length of the sorbent in the SBPFM, θ is the water content in the SBPFM, and R_d is the retardation of the resident tracer on the sorbent, and t is the sampling duration. The formulation used in this report assumed that there is no convergence or divergence of flow through the well screen and PFM. The convergence factors are currently assumed to be unity but can be estimated using values for hydraulic conductivities of the PFM, screen intervals and sediment hydraulic conductivity and anisotropy (see Klammler et al., 2007 for horizontal flow through wells).

The UF group shipped 48 SBPFMs on March 20, 2015 to the Tetra Tech office in Germantown, Maryland for installation by the Tetra Tech team. The SBPFMs were deployed in 11 transects each with four SBPFMs extending from near the shoreline toward the center of the creek (Figure 1). Installation involved pushing and pounding the SBPFMs until reaching a depth of about 2 feet with the upper screen interval just below

the sediment surface. The SBPFMs were installed between 3/24/15 and 3/26/15. This formed a 4 by 11 grid covering approximately 1600 feet along the shoreline of Frog Mortar Creek. One additional transect was conducted in which the SBPFMs were driven deeper to a depth of 4 feet into the sediments at transect number 5 (PFM 51 through 54). The SBPFMs were retrieved after a period of two weeks during the period 4/7/2015 to 4/9/2015 and shipped for sampling and analysis at the University of Florida laboratory. Analysis was conducted over the next three weeks.

Results

The 48 PFMs deployed in the 4 by 11 transect were retrieved using GPS to locate each drive point. During this deployment PFMs were identified starting from PFM7 through PFM 54. Six PFMs (PFM1 through PFM6) were deployed in a preliminary trial and those results are not included in this report. Of the 48 PFMs deployed, 44 of the SBPFMs were located and recovered while PFMs 11, 12, 28 and 41 were not recovered. The 44 PFMs were analyzed for both tracers and contaminants by segmenting the PFMs into either 4 or 10 vertically discretized samples. The transects near the center of the 4 by 11 grid, near the suspected landfill discharge, were sampled at a higher resolution to attempt to more quantitatively assess the influence of tidal fluctuations on the SBPFM performance.

Darcy Flux in Sediments

The results of the tracer data, used to estimate groundwater Darcy flux and direction, are presented in three primary Figures 2-4. Figure 2 shows the magnitude of measured vertical upward flux for all of the PFMs. The center section of each PFM contained activated carbon with a suite of tracers used to quantify water flow. The loss of tracer in this section was used to determine the cumulative flow through the device. That flow was then proportioned to vertical upward vs. vertical downward flow based on the amount of tracer mass found above or below the center section containing tracers (tracer results for each PFM are provided in Appendix A). This was done using a simple approach where the relative mass above verses the relative mass below the tracer section was calculated. Based on the relative (or percent) of mass of tracer above the center section that portion of the total flow was assigned as Up Flow (Figure 2). The distribution of Up Flow can is provided in Figure 2 and ranged from zero to a maximum of about 38 cm/day. Two higher Up Flow zones can be seen in the Northern and Southern ends of the grid network.

Based on the amount of tracer observed below the center tracer zone, Down Flow was calculated. The magnitude and distribution of Down Flow is provided in Figure 3. The maximum Down Flow was about 23 cm/day. The distribution of Down Flow shows mainly high fluxes near the center of the grid in contrast to the observed Up Flow distribution. The quantification of up and down flow can then be used to calculate a net flow for each SBPFM. The net flow is provided in Figure 4. The majority of the flow was upward as anticipated based on the observed contaminants in Frog Mortar Creek. The maximum observed net groundwater flow was about 37 cm/day while the maximum

net downward flow was about -17 cm/day. It is very clear in this figure that Up Flow dominates in the Northern and Southern section of the grid while Down Flow was evident in the center. The average of all net flows was 6.7 cm/day indicating an overall net positive flow.

Contaminant Flux in Sediments

The contaminant flux is calculated based on the mass extracted from the activated carbon samples collected from the segmented SBPFM. In order to increase the likelihood of contaminant detection a short, one inch, section of the PFM was collected from the bottom. In general the majority of the contaminant mass was recovered from the bottom segment. Much less mass was collected from segments further into the device (all segmented contaminant data is provided in Appendix A). A summary of contaminant mass flux calculated for each contaminant (TCE, 12DCE, VC) is provide in Figures 5 through 8. The first observation is that the contaminant flux is dominated by samples in the third transect starting with PFM15 which has the highest TCE mass flux at 2700 $mg/m^2/day$. The next highest mass flux zone is at transect seven starting with PFM31 with a TCE mass flux of about 1200 $mg/m^2/day$. These two zones dominate the mass flux distribution.

Figures 6 through 8 provide a breakdown of mass flux by contaminant and upward verses downward mass flux. In general the mass flux is dominated by TCE and is mainly upward flux. A small amount of downward mass flux was observed at many locations but was much lower than the observed upward flux. This may be due to the presence of contaminants in the surface water that would flow into the sediments during tidal cycling. This assumption might be evaluated through using a simple site mass balance approach. The effect of tidal cycling has not been evaluated for the PFM deployments. Transducer data has not been consider yet in this analysis.

Spatial Distribution of Darcy and Contaminant Flux

A more detailed assessment of the Darcy flux through the 4 by 11 grid is provided in Figures 9 and 10. The data are plotted by transect to visualize the Darcy flux within the grid deployment of SBPFMs. A general observation is that the Darcy flux tends to decrease somewhat with distance offshore. This may be related to the presence of finer grained sediments with increasing water depth. Some correlation may be investigated with water depth or the presence of finer sediments based on SBPFM installation data.

The contaminant mass flux distribution is presented in Figures 11-13. For each contaminant the dominant mass discharge is found at PFM 15 with smaller but significant amounts at PFM31. The plots are provided on log scale so the lower mass flux values that were dominated by PFM15 can be observed. The distribution of TCE mass flux has been crudely evaluated through a contour plot using Surfer (Figures 14 through 16). The figures again shows how the mass flux is dominated by transects 3 and 7. The mass discharge associated with each transect was calculated and scaled to the total mass discharge to find that 82% of the mass discharge was associated with transect 3 while

14% was associated with transect 7. The total mass discharge for the grid which covered an area of about 7 acres was 2900 g/day for TCE, 760 g/day for 12DCE and 230 g/day for VC. These values are quite high but as discussed in the next section may be subject to flow convergence.

Flow Convergence through the SBPFM

All of the SBPFM data discussed above has assumed that the flow and contaminant flux through the device is the same as that in the sediments in the absence of the SBPFM. When the SBPFM is driven into the sediments it naturally creates a short circuit pathway for flow of water and contaminants vertically thorough the device. The magnitude of that flow convergence depends on several factors including the hydraulic conductivity of the sorbent media inside the device, the diameter, the length between the intake and exhaust screens, the hydraulic conductivity of the sediments and finally the anisotropy of the sediments. We are currently formulating analytical solutions to the flow field associated with the SBPFM deployments. A Ph.D. student is completing this effort as part of the dissertation. Using the conditions for the field deployments of the SBPFMs, 2 inch diameter with about 15 inches between screens and a hydraulic conductivity for the activated carbon of 300 m/day and assuming a much lower hydraulic conductivity for the sediments of 3 m/day (two orders of magnitude lower) the calculated convergence is 30. This value is quite high and would indicate that all values reported above should be decreased by a factor of 30. For the overall integrated TCE mass flux estimate of 2900 g/day this value would decline to about 100 g/day. This is a significant change and needs to be further evaluated. One possible comparison is with values obtained through modeling efforts and simple mass balance approach. The convergence factor would not likely change the relative spatial distribution of water and mass flux as the convergence is fairly insensitive to the hydraulic conductivity of the sediments assuming the hydraulic conductivity contrast is high.

Application of Shallow and Deep SBPFM Deployments

In one of the transects of four SBPFM deployments, two sets of units were applied at two different depths. The goal was to assess the change in mass flux as the groundwater discharge approached the sediment water interface. Looking at the net mass flux comparison between the two sets of SBPFMs deployed, one finds no evidence of change in mass flux of the three constituents evaluated. Looking closer and upward and downward mass flux there may be evidence for some degradation of the parent compound TCE. Further evaluation of this data set is required to fully interpret the results in particularly considering the effect of tidal cycling.

Summary

The application of 48 SBPFMs at the Frog Mortar Creek site have provided a data set that can be used to assess the distribution of mass flux into surface water along the shoreline adjacent to the original source of chlorinated solvents. This data set provides a general understanding of the magnitude and distribution of both Darcy and contaminant mass

flux through the sediments of Frog Mortar Creek. The mass flux and integrated mass discharge values determined through SBPFM deployments can be compared to other approaches such as modeling and simple mass balances to further improve the conceptual model for the site. The contaminant mass flux distribution determined through the grid network deployment may be of valuable for targeting remedial efforts to address zones of high contaminant mass flux. Finally, this data set provided a baseline assessment that can be later used to evaluate the performance of remedial efforts aimed at reducing mass flux and mass discharge to Frog Mortar Creek.
